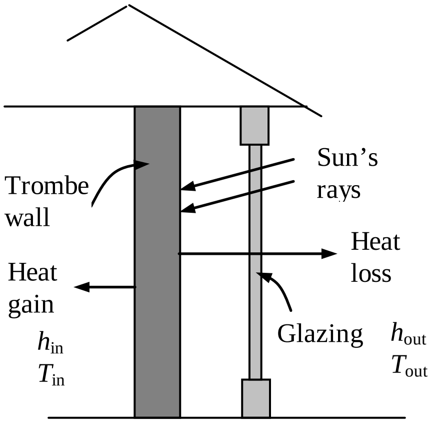
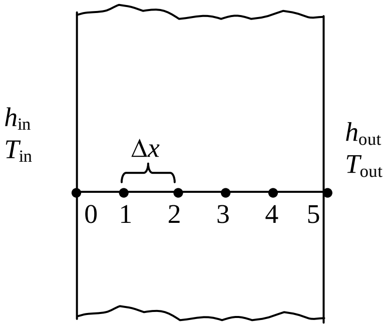
Properties The wall properties are given to be k = 0.70 W/m·°C, $\alpha = 0.44\times10^{-6}\ \text{m}^2/\text{s}$, and $\kappa = 0.76$. The hourly variation of monthly average ambient temperature and solar heat flux incident on a vertical surface is given to be

Time of day	Ambient Temperature, °C	Solar insolation W/m^2
7am-10am	0	375
10am-1pm	4	750
1pm-4pm	6	580
4pm-7pm	1	95
7pm-10pm	-2	0
10pm-1am	-3	0
1am-4am	-4	0
4am-7am	-4	0





Analysis The nodal spacing is given to be Δx = 0.05 m, Then the number of nodes becomes $M = L/\Delta x + 1$ = 0.30/0.05+1 = 7. This problem involves 7 unknown nodal temperatures, and thus we need to have 7 equations. Nodes 1, 2, 3, 4, and 5 are interior nodes, and thus for them we can use the general explicit finite difference relation expressed as

$$T_{m-1}^i - 2T_m^i + T_{m+1}^i + \frac{\dot{g}_m^i \Delta x^2}{k} = \frac{T_m^{i+1} - T_m^i}{\tau} \ \rightarrow\ T_m^{i+1} = \tau(T_{m-1}^i + T_{m+1}^i) + (1-2\tau)T_m^i$$

The finite difference equation for boundary nodes 0 and 6 are obtained by applying an energy balance on the half volume elements and taking the direction of all heat transfers to be towards the node under consideration:

Node 0: $h_{\text{in}} A(T_{\text{in}}^i - T_0^i) + kA\dfrac{T_1^i - T_0^i}{\Delta x} = \rho A \dfrac{\Delta x}{2} C \dfrac{T_0^{i+1} - T_0^i}{\Delta t}$

or $\quad T_0^{i+1} = \left(1 - 2\tau - 2\tau\dfrac{h_{\text{in}}\Delta x}{k}\right)T_0^i + 2\tau T_1^i + 2\tau\dfrac{h_{\text{in}}\Delta x}{k}T_{\text{in}}$

Node 1 $(m=1)$: $T_1^{i+1} = \tau(T_0^i + T_2^i) + (1-2\tau)T_1^i$

Node 2 $(m=2)$: $T_2^{i+1} = \tau(T_1^i + T_3^i) + (1-2\tau)T_2^i$

Node 3 $(m=3)$: $T_3^{i+1} = \tau(T_2^i + T_4^i) + (1-2\tau)T_3^i$

Node 4 $(m=4)$: $T_4^{i+1} = \tau(T_3^i + T_5^i) + (1-2\tau)T_4^i$

Node 5 $(m=5)$: $T_5^{i+1} = \tau(T_4^i + T_6^i) + (1-2\tau)T_5^i$

Node 6 $$h_{\text{out}} A(T_{\text{out}}^i - T_6^i) + \kappa A\dot{q}_{\text{solar}}^i + kA\frac{T_5^i - T_6^i}{\Delta x} = \rho A\frac{\Delta x}{2}C\frac{T_6^{i+1} - T_6^i}{\Delta t}$$

or $$T_6^{i+1} = \left(1 - 2\tau - 2\tau\frac{h_{\text{out}}\Delta x}{k}\right)T_6^i + 2\tau T_5^i + 2\tau\frac{h_{\text{out}}\Delta x}{k}T_{\text{out}}^i + 2\tau\frac{\kappa\dot{q}_{\text{solar}}^i\Delta x}{k}$$

where L = 0.30 m, k = 0.70 W/m.°C, $\alpha = 0.44\times10^{-6}\ \text{m}^2/\text{s}$, T_{out} and $\dot{q}_{\text{solar}}$ are as given in the table, $\kappa = 0.76$ h_{out} = 3.4 W/m^2.°C, T_{in} = 20°C, h_{in} = 9.1 W/m^2.°C, and Δx = 0.05 m.

Next we need to determine the upper limit of the time step Δt from the stability criteria since we are using the explicit method. This requires the identification of the smallest primary coefficient in the system. We know that the boundary nodes are more restrictive than the interior nodes, and thus we examine the formulations of the boundary nodes 0 and 6 only. The smallest and thus the most restrictive primary coefficient in this case is the coefficient of T_0^i in the formulation of node 0 since $h_{\text{in}} > h_{\text{out}}$, and thus

$$1 - 2\tau - 2\tau\frac{h_{\text{in}}\Delta x}{k} < 1 - 2\tau - 2\tau\frac{h_{\text{out}}\Delta x}{k}$$

Therefore, the stability criteria for this problem can be expressed as

$$1 - 2\tau - 2\tau\frac{h_{\text{in}}\Delta x}{k} \geq 0 \quad\rightarrow\quad \tau \leq \frac{1}{2(1 + h_{\text{in}}\Delta x / k)} \quad\rightarrow\quad \Delta t \leq \frac{\Delta x^2}{2\alpha(1 + h_{\text{in}}\Delta x / k)}$$

since $\tau = \alpha\Delta t / \Delta x^2$. Substituting the given quantities, the maximum allowable the time step becomes

$$\Delta t \leq \frac{(0.05\,\text{m})^2}{2(0.44\times10^{-6}\ \text{m}^2/\text{s})[1 + (9.1\,\text{W/m}^2.°\text{C})(0.05\,\text{m})/(0.70\,\text{W/m.°C})]} = 1722\,\text{s}$$

Therefore, any time step less than 1722 s can be used to solve this problem. For convenience, let us choose the time step to be Δt = 900 s = 15 min. Then the mesh Fourier number becomes

$$\tau = \frac{\alpha\Delta t}{\Delta x^2} = \frac{(0.44\times10^{-6}\ \text{m}^2/\text{s})(900\,\text{s})}{(0.05\,\text{m})^2} = 0.1584$$

Initially (at 7 am or t = 0), the temperature of the wall is said to vary linearly between 20°C at node 0 and 0°C at node 6. Noting that there are 6 nodal spacing of equal length, the temperature change between two neighboring nodes is (20 - 0)°F/6 = 3.33°C. Therefore, the initial nodal temperatures are

$$T_0^0 = 20°\text{C},\ T_1^0 = 16.66°\text{C},\ T_2^0 = 13.33°\text{C},\ T_3^0 = 10°\text{C},\ T_4^0 = 6.66°\text{C},\ T_5^0 = 3.33°\text{C},\ T_6^0 = 0°\text{C}$$

Substituting the given and calculated quantities, the nodal temperatures after 6, 12, 18, 24, 30, 36, 42, and 48 h are calculated and presented in the following table and chart.

Time	Time step, *i*	Nodal temperatures, °C						
		T_0	T_1	T_2	T_3	T_4	T_5	T_6
0 h (7am)	0	20.0	16.7	13.3	10.0	6.66	3.33	0.0
6 h (1 pm)	24	17.5	16.1	15.9	18.1	24.8	38.8	61.5
12 h (7 pm)	48	21.4	22.9	25.8	30.2	34.6	37.2	35.8
18 h (1 am)	72	22.9	24.6	26.0	26.6	26.0	23.5	19.1
24 h (7 am)	96	21.6	22.5	22.7	22.1	20.4	17.7	13.9
30 h (1 pm)	120	21.0	21.8	23.4	26.8	34.1	47.6	68.9
36 h (7 pm)	144	24.1	27.0	31.3	36.4	41.1	43.2	40.9
42 h (1 am)	168	24.7	27.6	29.9	31.1	30.5	27.8	22.6
48 h (7 am)	192	23.0	24.6	25.5	25.2	23.7	20.7	16.3

The rate of heat transfer from the Trombe wall to the interior of the house during each time step is determined from Newton's law of cooling using the average temperature at the inner surface of the wall (node 0) as

$$Q^i_{\text{Trumbe wall}} = \dot{Q}^i_{\text{Trumbe wall}}\Delta t = h_{\text{in}}A(T_0^i - T_{\text{in}})\Delta t = h_{\text{in}}A[(T_0^i + T_0^{i-1})/2 - T_{\text{in}}]\Delta t$$

Therefore, the amount of heat transfer during the first time step (*i* = 1) or during the first 15 min period is

$$Q^1_{\text{Trumbe wall}} = h_{\text{in}}A[(T_0^1 + T_0^0)/2 - T_{\text{in}}]\Delta t = (9.1\ \text{W/m}^2.°\text{C})(2.8\times 7\ \text{m}^2)[(68.3+70)/2 - 70°\text{F}](0.25\ \text{h}) = -96.8\ \text{Btu}$$

The negative sign indicates that heat is transferred to the Trombe wall from the air in the house which represents a heat loss. Then the total heat transfer during a specified time period is determined by adding the heat transfer amounts for each time step as

$$Q_{\text{Trumbe wall}} = \sum_{i=1}^{I} Q^i_{\text{Trumbe wall}} = \sum_{i=1}^{I} h_{\text{in}}A[(T_0^i + T_0^{i-1})/2 - T_{\text{in}}]\Delta t$$

where *I* is the total number of time intervals in the specified time period. In this case *I* = 48 for 12 h, 96 for 24 h, etc. Following the approach described above using a computer, the amount of heat transfer between the Trombe wall and the interior of the house is determined to be

$Q_{\text{Trombe wall}}$ = - 3421 kJ after 12 h

$Q_{\text{Trombe wall}}$ = 1753 kJ after 24 h

$Q_{\text{Trombe wall}}$ = 5393 kJ after 36 h

$Q_{\text{Trombe wall}}$ = 15,230 kJ after 48 h

Discussion Note that the interior temperature of the Trombe wall drops in early morning hours, but then rises as the solar energy absorbed by the exterior surface diffuses through the wall. The exterior surface temperature of the Trombe wall rises from 0 to 61.5°C in just 6 h because of the solar energy absorbed, but then drops to 13.9°C by next morning as a result of heat loss at night. Therefore, it may be worthwhile to cover the outer surface at night to minimize the heat losses.

Also the house loses 3421 kJ through the Trombe wall the 1st daytime as a result of the low start-up temperature, but delivers about 13,500 kJ of heat to the house the second day. It can be shown that the Trombe wall will deliver even more heat to the house during the 3rd day since it will start the day at a higher average temperature.

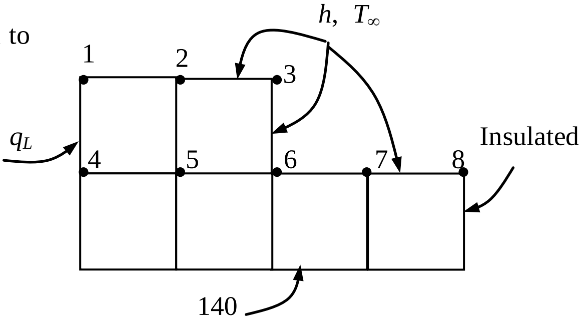
5-87 Heat conduction through a long L-shaped solid bar with specified boundary conditions is considered. The temperature at the top corner (node #3) of the body after 2, 5, and 30 min is to be determined with the transient explicit finite difference method.

Assumptions **1** Heat transfer through the body is given to be transient and two-dimensional. **2** Thermal conductivity is constant. **3** Heat generation is uniform.



Properties The conductivity and diffusivity are given to be k = 15 W/m·°C and $\alpha = 3.2\times10^{-6}\ \text{m}^2/\text{s}$.

Analysis The nodal spacing is given to be Δx=Δx=l=0.015 m. The explicit finite difference equations are determined on the basis of the energy balance for the transient case expressed as

$$\sum_{\text{All sides}} \dot{Q}^i + \dot{G}^{\text{i}}_{\text{element}} = \rho V_{\text{element}} C \frac{T_m^{i+1} - T_m^i}{\Delta t}$$

The quantities $h,\ T_\infty,\ \dot{g}$, and $\dot{q}_R$ do not change with time, and thus we do not need to use the superscript i for them. Also, the energy balance expressions can be simplified using the definitions of thermal diffusivity $\alpha = k/(\rho C)$ and the dimensionless mesh Fourier number $\tau = \alpha\Delta t/l^2$ where $\Delta x = \Delta y = l$. We note that all nodes are boundary nodes except node 5 that is an interior node. Therefore, we will have to rely on energy balances to obtain the finite difference equations. Using energy balances, the finite difference equations for each of the 8 nodes are obtained as follows:

Node 1: $\dot{q}_L \dfrac{l}{2} + h\dfrac{l}{2}(T_\infty - T_1^i) + k\dfrac{l}{2}\dfrac{T_2^i - T_1^i}{l} + k\dfrac{l}{2}\dfrac{T_4^i - T_1^i}{l} + \dot{g}_0 \dfrac{l^2}{4} = \rho\dfrac{l^2}{4}C\dfrac{T_1^{i+1} - T_1^i}{\Delta t}$

Node 2: $hl(T_\infty - T_2^i) + k\dfrac{l}{2}\dfrac{T_1^i - T_2^i}{l} + k\dfrac{l}{2}\dfrac{T_3^i - T_2^i}{l} + kl\dfrac{T_5^i - T_2^i}{l} + \dot{g}_0 \dfrac{l^2}{2} = \rho\dfrac{l^2}{2}C\dfrac{T_2^{i+1} - T_2^i}{\Delta t}$

Node 3: $hl(T_\infty - T_3^i) + k\dfrac{l}{2}\dfrac{T_2^i - T_3^i}{l} + k\dfrac{l}{2}\dfrac{T_6^i - T_3^i}{l} + \dot{g}_0 \dfrac{l^2}{4} = \rho\dfrac{l^2}{4}C\dfrac{T_3^{i+1} - T_3^i}{\Delta t}$

(It can be rearranged as $T_3^{i+1} = \left(1 - 4\tau - 4\tau\dfrac{hl}{k}\right)T_3^i + 2\tau\left(T_4^i + T_6^i + 2\dfrac{hl}{k}T_\infty + \dfrac{\dot{g}_3 l^2}{2k}\right)$)

Node 4: $\dot{q}_L l + k\dfrac{l}{2}\dfrac{T_1^i - T_4^i}{l} + k\dfrac{l}{2}\dfrac{140 - T_4^i}{l} + kl\dfrac{T_5^i - T_4^i}{l} + \dot{g}_0 \dfrac{l^2}{2} = \rho\dfrac{l^2}{2}C\dfrac{T_4^{i+1} - T_4^i}{\Delta t}$

Node 5 (interior): $T_5^{i+1} = (1 - 4\tau)T_5^i + \tau\left(T_2^i + T_4^i + T_6^i + 140 + \dfrac{\dot{g}_0 l^2}{k}\right)$

Node 6: $hl(T_\infty - T_6^i) + k\dfrac{l}{2}\dfrac{T_3^i - T_6^i}{l} + kl\dfrac{T_5^i - T_6^i}{l} + kl\dfrac{140 - T_6^i}{l} + k\dfrac{l}{2}\dfrac{T_7^i - T_6^i}{l} + \dot{g}_0 \dfrac{3l^2}{4} = \rho\dfrac{3l^2}{4}C\dfrac{T_6^{i+1} - T_6^i}{\Delta t}$

Node 7: $hl(T_\infty - T_7^i) + k\dfrac{l}{2}\dfrac{T_6^i - T_7^i}{l} + k\dfrac{l}{2}\dfrac{T_8^i - T_7^i}{l} + kl\dfrac{140 - T_7^i}{l} + \dot{g}_0 \dfrac{l^2}{2} = \rho\dfrac{l^2}{2}C\dfrac{T_7^{i+1} - T_7^i}{\Delta t}$

Node 8: $h\dfrac{l}{2}(T_\infty - T_8^i) + k\dfrac{l}{2}\dfrac{T_7^i - T_8^i}{l} + k\dfrac{l}{2}\dfrac{140 - T_8^i}{l} + \dot{g}_0 \dfrac{l^2}{4} = \rho\dfrac{l^2}{4}C\dfrac{T_8^{i+1} - T_8^i}{\Delta t}$

where $\dot{g}_0 = 2\times10^7\ \text{W/m}^3$, $\dot{q}_L = 8000\ \text{W/m}^2$, l = 0.015 m, k =15 W/m·°C, h = 80 W/m^2·°C, and T_∞ =25°C.

The upper limit of the time step Δt is determined from the stability criteria that requires the coefficient of T_m^i in the T_m^{i+1} expression (the primary coefficient) be greater than or equal to zero for all nodes. The smallest primary coefficient in the 8 equations above is the coefficient of T_3^i in the T_3^{i+1} expression since it is exposed to most convection per unit volume (this can be verified), and thus the stability criteria for this problem can be expressed as

$$1-4\tau-4\tau\frac{hl}{k}\geq 0 \quad\rightarrow\quad \tau\leq\frac{1}{4(1+hl/k)} \quad\rightarrow\quad \Delta t\leq\frac{l^2}{4\alpha(1+hl/k)}$$

since $\tau=\alpha\Delta t/l^2$. Substituting the given quantities, the maximum allowable value of the time step is determined to be

$$\Delta t\leq\frac{(0.015\,\text{m})^2}{4(3.2\times10^{-6}\ \text{m}^2/\text{s})[1+(80\ \text{W/m}^2.^\circ\text{C})(0.015\,\text{m})/(15\ \text{W/m}.^\circ\text{C})]}=16.3\,\text{s}$$

Therefore, any time step less than 16.3 s can be used to solve this problem. For convenience, we choose the time step to be Δt = 15 s. Then the mesh Fourier number becomes

$$\tau=\frac{\alpha\Delta t}{l^2}=\frac{(3.2\times10^{-6}\ \text{m}^2/\text{s})(15\,\text{s})}{(0.015\,\text{m})^2}=0.2133 \qquad (\text{for}\quad \Delta t = 15\ \text{s})$$

Using the specified initial condition as the solution at time t = 0 (for i = 0), sweeping through the 9 equations above will give the solution at intervals of 15 s. Using a computer, the solution at the upper corner node (node 3) is determined to be **441, 520**, and **529°C** at 2, 5, and 30 min, respectively. It can be shown that the steady state solution at node 3 is 531°C.

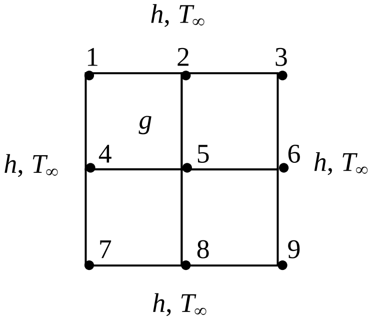
5-89 A long solid bar is subjected to transient two-dimensional heat transfer. The centerline temperature of the bar after 10 min and after steady conditions are established are to be determined.

Assumptions **1** Heat transfer through the body is given to be transient and two-dimensional. **2** Heat is generated uniformly in the body. **3** The heat transfer coefficient also includes the radiation effects.

Properties The conductivity and diffusivity are given to be k = 28 W/m·°C and $\alpha = 12\times10^{-6}\ \text{m}^2/\text{s}$.



Analysis The nodal spacing is given to be Δx=Δx=l=0.1 m. The explicit finite difference equations are determined on the basis of the energy balance for the transient case expressed as

$$\sum_{\text{All sides}} \dot{Q}^i + \dot{G}^{\text{i}}_{\text{element}} = \rho V_{\text{element}} C \frac{T_m^{i+1} - T_m^i}{\Delta t}$$

The quantities h, T_∞, and $\dot{g}_0$ do not change with time, and thus we do not need to use the superscript i for them. The general explicit finite difference form of an interior node for transient two-dimensional heat conduction is expressed as

$$T_{\text{node}}^{i+1} = \tau(T_{\text{left}}^{\text{i}} + T_{\text{top}}^{\text{i}} + T_{\text{right}}^{\text{i}} + T_{\text{bottom}}^{\text{i}}) + (1-4\tau)T_{\text{node}}^{\text{i}} + \tau\frac{\dot{g}_{\text{node}}^{\text{i}} l^2}{k}$$

There is symmetry about the vertical, horizontal, and diagonal lines passing through the center. Therefore, $T_1 = T_3 = T_7 = T_9$ and $T_2 = T_4 = T_6 = T_8$, and T_1, T_2, and T_5 are the only 3 unknown nodal temperatures, and thus we need only 3 equations to determine them uniquely. Also, we can replace the symmetry lines by insulation and utilize the mirror-image concept when writing the finite difference equations for the interior nodes. The finite difference equations for boundary nodes are obtained by applying an energy balance on the volume elements and taking the direction of all heat transfers to be towards the node under consideration:

Node 1: $hl(T_\infty - T_1^i) + k\dfrac{l}{2}\dfrac{T_2^i - T_1^i}{l} + k\dfrac{l}{2}\dfrac{T_4^i - T_1^i}{l} + \dot{g}_0\dfrac{l^2}{4} = \rho\dfrac{l^2}{4}C\dfrac{T_1^{i+1} - T_1^i}{\Delta t}$

Node 2: $h\dfrac{l}{2}(T_\infty - T_2^i) + k\dfrac{l}{2}\dfrac{T_1^i - T_2^i}{l} + k\dfrac{l}{2}\dfrac{T_5^i - T_2^i}{l} + \dot{g}_0\dfrac{l^2}{4} = \rho\dfrac{l^2}{4}C\dfrac{T_2^{i+1} - T_2^i}{\Delta t}$

Node 5 (interior): $T_5^{i+1} = (1-4\tau)T_5^i + \tau\left(4T_2^i + \dfrac{\dot{g}_0 l^2}{k}\right)$

where $\dot{g}_0 = 8\times10^5$ W/m^3, l = 0.1 m, and k = 28 W/m·°C, h = 45 W/m^2·°C, and T_∞ =30°C.

The upper limit of the time step Δt is determined from the stability criteria that requires the coefficient of T_m^i in the T_m^{i+1} expression (the primary coefficient) be greater than or equal to zero for all nodes. The smallest primary coefficient in the 3 equations above is the coefficient of T_1^i in the T_1^{i+1} expression since it is exposed to most convection per unit volume (this can be verified), and thus the stability criteria for this problem can be expressed as

$$1 - 4\tau - 4\tau\frac{hl}{k} \geq 0 \quad \rightarrow \quad \tau \leq \frac{1}{4(1+hl/k)} \quad \rightarrow \quad \Delta t \leq \frac{l^2}{4\alpha(1+hl/k)}$$

since $\tau = \alpha\Delta t / l^2$. Substituting the given quantities, the maximum allowable value of the time step is determined to be

$$\Delta t \le \frac{(0.1\,\text{m})^2}{4(12\times10^{-6}\ \text{m}^2/\text{s})[1+(45\ \text{W/m}^2.\text{°C})(0.1\,\text{m})/(28\ \text{W/m.°C})]} = 179\ \text{s}$$

Therefore, any time step less than 179 s can be used to solve this problem. For convenience, we choose the time step to be Δt = 60 s. Then the mesh Fourier number becomes

$$\tau = \frac{\alpha \Delta t}{l^2} = \frac{(12\times10^{-6}\ \text{m}^2/\text{s})(60\,\text{s})}{(0.1\,\text{m})^2} = 0.072 \qquad (\text{for}\quad \Delta t = 60\ \text{s})$$

Using the specified initial condition as the solution at time t = 0 (for i = 0), sweeping through the 3 equations above will give the solution at intervals of 1 min. Using a computer, the solution at the center node (node 5) is determined to be **217.2°C**, 302.8°C, 379.3°C, 447.7°C, 508.9°C, 612.4°C, 695.1°C, and 761.2°C at 10, 15, 20, 25, 30, 40, 50, and 60 min, respectively. Continuing in this manner, it is observed that steady conditions are reached in the medium after about 6 hours for which the temperature at the center node is **1023°C**.

5-90E A plain window glass initially at a uniform temperature is subjected to convection on both sides. The transient finite difference formulation of this problem is to be obtained, and it is to be determined how long it will take for the fog on the windows to clear up (i.e., for the inner surface temperature of the window glass to reach 54°F).

Assumptions **1** Heat transfer is one-dimensional since the window is large relative to its thickness. **2** Thermal conductivity is constant. **3** Radiation heat transfer is negligible.

Properties The conductivity and diffusivity are given to be k = 0.48 Btu/h.ft·°F and $\alpha = 4.2\times10^{-6}\ \text{ft}^2/\text{s}$.

Analysis The nodal spacing is given to be Δx = 0.125 in. Then the number of nodes becomes $M = L/\Delta x + 1$ = 0.375/0.125+1 = 4. This problem involves 4 unknown nodal temperatures, and thus we need to have 4 equations. Nodes 2 and 3 are interior nodes, and thus for them we can use the general explicit finite difference relation expressed as

$$T_{m-1}^i - 2T_m^i + T_{m+1}^i + \frac{\dot{g}_m^i \Delta x^2}{k} = \frac{T_m^{i+1} - T_m^i}{\tau} \rightarrow T_m^{i+1} = \tau(T_{m-1}^i + T_{m+1}^i) + (1-2\tau)T_m^i$$

since there is no heat generation. The finite difference equation for nodes 1 and 4 on the surfaces subjected to convection is obtained by applying an energy balance on the half volume element about the node, and taking the direction of all heat transfers to be towards the node under consideration:

$$\text{Node 1 (convection)}: \quad h_i(T_i - T_1^i) + k\frac{T_2^i - T_1^i}{\Delta x} = \rho\frac{\Delta x}{2}C\frac{T_1^{i+1} - T_1^i}{\Delta t}$$

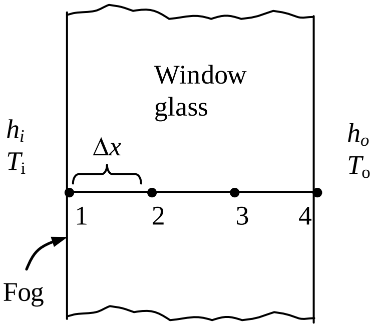
$$\textit{or} \quad T_1^{i+1} = \left(1 - 2\tau - 2\tau\frac{h_i \Delta x}{k}\right)T_1^i + 2\tau T_2^i + 2\tau\frac{h_i\Delta x}{k}T_i$$

$$\text{Node 2 (interior)}: \quad T_2^{i+1} = \tau(T_1^i + T_3^i) + (1-2\tau)T_2^i$$

$$\text{Node 3 (interior)}: \quad T_3^{i+1} = \tau(T_2^i + T_4^i) + (1-2\tau)T_3^i$$

$$\text{Node 4 (convection)}: \quad h_o(T_o - T_4^i) + k\frac{T_3^i - T_4^i}{\Delta x} = \rho\frac{\Delta x}{2}C\frac{T_4^{i+1} - T_4^i}{\Delta t}$$

$$\text{or} \quad T_4^{i+1} = \left(1 - 2\tau - 2\tau\frac{h_o\Delta x}{k}\right)T_4^i + 2\tau T_3^i + 2\tau\frac{h_o\Delta x}{k}T_o$$



where Δx = 0.125/12 ft , k = 0.48 Btu/h.ft·°F, h_i = 1.2 Btu/h.ft^2·°F, T_i =35+2*(t/60)°F (t in seconds), h_o = 2.6 Btu/h.ft^2·°F, and T_o =35°F. The upper limit of the time step Δt is determined from the stability criteria that requires all primary coefficients to be greater than or equal to zero. The coefficient of T_4^i is smaller in this case, and thus the stability criteria for this problem can be expressed as

$$1 - 2\tau - 2\tau\frac{h\Delta x}{k} \ge 0 \quad \rightarrow \quad \tau \le \frac{1}{2(1 + h\Delta x/k)} \quad \rightarrow \quad \Delta t \le \frac{\Delta x^2}{2\alpha(1 + h\Delta x/k)}$$

since $\tau = \alpha\Delta t/\Delta x^2$. Substituting the given quantities, the maximum allowable time step becomes

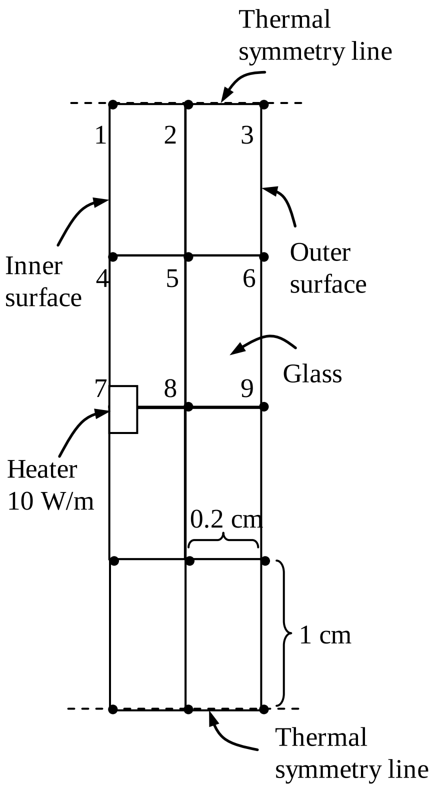
$$\Delta t \le \frac{(0.125/12\ \text{ft})^2}{2(4.2\times10^{-6}\ \text{ft}^2/\text{s})[1 + (2.6\ \text{Btu/h.ft}^2.°\text{F})(0.125/12\ \text{m})/(0.48\ \text{Btu/h.ft.°F})]} = 12.2\ \text{s}$$

Therefore, any time step less than 12.2 s can be used to solve this problem. For convenience, let us choose the time step to be Δt = 10 s. Then the mesh Fourier number becomes

$$\tau = \frac{\alpha\Delta t}{\Delta x^2} = \frac{(4.2\times10^{-6}\ \text{ft}^2/\text{s})(10\ \text{s})}{(0.125/12\ \text{ft})^2} = 0.3871$$

Substituting this value of τ and other given quantities, the time needed for the inner surface temperature of the window glass to reach 54°F to avoid fogging is determined to be *never*. This is because steady conditions are reached in about 156 min, and the inner surface temperature at that time is determined to be 48.0°F. Therefore, the window will will be fogged at all times.

5-91 The formation of fog on the glass surfaces of a car is to be prevented by attaching electric resistance heaters to the inner surfaces. The temperature distribution throughout the glass 15 min after the strip heaters are turned on and also when steady conditions are reached are to be determined using the explicit method.



Assumptions **1** Heat transfer through the glass is given to be transient and two-dimensional. **2** Thermal conductivity is constant. **3** There is heat generation only at the inner surface, which will be treated as prescribed heat flux.

Properties The conductivity and diffusivity are given to be k = 0.84 W/m·°C and $\alpha = 0.39\times10^{-6}\ \text{m}^2/\text{s}$.

Analysis The nodal spacing is given to be Δx = 0.2 cm and Δy = 1 cm. The explicit finite difference equations are determined on the basis of the energy balance for the transient case expressed as

$$\sum_{\text{All sides}} \dot{Q}^i + \dot{G}^{\text{i}}_{\text{element}} = \rho V_{\text{element}} C \frac{T_m^{i+1} - T_m^i}{\Delta t}$$

We consider only 9 nodes because of symmetry. Note that we do not have a square mesh in this case, and thus we will have to rely on energy balances to obtain the finite difference equations. Using energy balances, the finite difference equations for each of the 9 nodes are obtained as follows:

Node 1: $h_i \dfrac{\Delta y}{2}(T_i - T_1^i) + k\dfrac{\Delta x}{2}\dfrac{T_4^i - T_1^i}{\Delta y} + k\dfrac{\Delta y}{2}\dfrac{T_2^i - T_1^i}{\Delta x} = \rho C\dfrac{\Delta x}{2}\dfrac{\Delta y}{2}\dfrac{T_1^{i+1} - T_1^i}{\Delta t}$

Node 2: $k\dfrac{\Delta y}{2}\dfrac{T_1^i - T_2^i}{\Delta x} + k\dfrac{\Delta y}{2}\dfrac{T_3^i - T_2^i}{\Delta x} + k\Delta x\dfrac{T_5^i - T_2^i}{\Delta y} = \rho C\Delta x\dfrac{\Delta y}{2}\dfrac{T_2^{i+1} - T_2^i}{\Delta t}$

Node 3: $h_o \dfrac{\Delta y}{2}(T_o - T_3^i) + k\dfrac{\Delta x}{2}\dfrac{T_6^i - T_3^i}{\Delta y} + k\dfrac{\Delta y}{2}\dfrac{T_2^i - T_3^i}{\Delta x} = \rho C\dfrac{\Delta x}{2}\dfrac{\Delta y}{2}\dfrac{T_3^{i+1} - T_3^i}{\Delta t}$

Node 4: $h_i\Delta y(T_i - T_4^i) + k\dfrac{\Delta x}{2}\dfrac{T_1^i - T_4^i}{\Delta y} + k\dfrac{\Delta x}{2}\dfrac{T_7^i - T_4^i}{\Delta y} + k\Delta y\dfrac{T_5^i - T_4^i}{\Delta x} = \rho C\Delta y\dfrac{\Delta x}{2}\dfrac{T_4^{i+1} - T_4^i}{\Delta t}$

Node 5: $k\Delta y\dfrac{T_4^i - T_5^i}{\Delta x} + k\Delta y\dfrac{T_6^i - T_5^i}{\Delta x} + k\Delta x\dfrac{T_8^i - T_5^i}{\Delta y} + k\Delta x\dfrac{T_2^i - T_5^i}{\Delta y} = \rho C\Delta x\Delta y\dfrac{T_5^{i+1} - T_5^i}{\Delta t}$

Node 6: $h_o\Delta y(T_i - T_6^i) + k\dfrac{\Delta x}{2}\dfrac{T_3^i - T_6^i}{\Delta y} + k\dfrac{\Delta x}{2}\dfrac{T_9^i - T_6^i}{\Delta y} + k\Delta y\dfrac{T_5^i - T_6^i}{\Delta x} = \rho C\Delta y\dfrac{\Delta x}{2}\dfrac{T_6^{i+1} - T_6^i}{\Delta t}$

Node 7: $5\ \text{W} + h_i \dfrac{\Delta y}{2}(T_i - T_7^i) + k\dfrac{\Delta x}{2}\dfrac{T_4^i - T_7^i}{\Delta y} + k\dfrac{\Delta y}{2}\dfrac{T_8^i - T_7^i}{\Delta x} = \rho C\dfrac{\Delta x}{2}\dfrac{\Delta y}{2}\dfrac{T_7^{i+1} - T_7^i}{\Delta t}$

Node 8: $k\dfrac{\Delta y}{2}\dfrac{T_7^i - T_8^i}{\Delta x} + k\dfrac{\Delta y}{2}\dfrac{T_9^i - T_8^i}{\Delta x} + k\Delta x\dfrac{T_5^i - T_8^i}{\Delta y} = \rho C\Delta x\dfrac{\Delta y}{2}\dfrac{T_8^{i+1} - T_8^i}{\Delta t}$

Node 9: $h_o \dfrac{\Delta y}{2}(T_o - T_9^i) + k\dfrac{\Delta x}{2}\dfrac{T_6^i - T_9^i}{\Delta y} + k\dfrac{\Delta y}{2}\dfrac{T_8^i - T_9^i}{\Delta x} = \rho C\dfrac{\Delta x}{2}\dfrac{\Delta y}{2}\dfrac{T_9^{i+1} - T_9^i}{\Delta t}$

where k = 0.84 W/m.°C, $\alpha = k/\rho C = 0.39 \times 10^{-6}\ \mathrm{m^2/s}$, $T_i = T_o$ = -3°C h_i = 6 W/m^2.°C, h_o = 20 W/m^2.°C, Δx = 0.002 m, and Δy = 0.01 m.

The upper limit of the time step Δt is determined from the stability criteria that requires the coefficient of T_m^i in the T_m^{i+1} expression (the primary coefficient) be greater than or equal to zero for all nodes. The smallest primary coefficient in the 9 equations above is the coefficient of T_9^i in the T_6^{i+1} expression since it is exposed to most convection per unit volume (this can be verified). The equation for node 6 can be rearranged as

$$T_6^{i+1} = \left[1 - 2\alpha\Delta t\left(\frac{h_o}{k\Delta x} + \frac{1}{\Delta y^2} + \frac{1}{\Delta x^2}\right)\right]T_6^i + 2\alpha\Delta t\left(\frac{h_o}{k\Delta x}T_0 + \frac{T_3^i + T_9^i}{\Delta y^2} + \frac{T_5^i}{\Delta x^2}\right)$$

Therefore, the stability criteria for this problem can be expressed as

$$1 - 2\alpha\Delta t\left(\frac{h_o}{k\Delta x} + \frac{1}{\Delta y^2} + \frac{1}{\Delta x^2}\right) \geq 0 \ \rightarrow\ \Delta \mathrm{t} \leq \frac{1}{2\alpha\left(\frac{h_o}{k\Delta x} + \frac{1}{\Delta y^2} + \frac{1}{\Delta x^2}\right)}$$

Substituting the given quantities, the maximum allowable value of the time step is determined to be

$$\text{or,}\quad \Delta \mathrm{t} \leq \frac{1}{2\times(0.39\times 10^{6}\ \mathrm{m^2}/s)\left(\frac{20\ \mathrm{W/m^2\cdot{}^\circ C}}{(0.84\ \mathrm{W/m\cdot{}^\circ C})(0.002\ \mathrm{m})} + \frac{1}{(0.002\ \mathrm{m})^2} + \frac{1}{(0.01\ \mathrm{m})^2}\right)} = 4.8\ \mathrm{s}$$

Therefore, any time step less than 4.8 s can be used to solve this problem. For convenience, we choose the time step to be Δt = 4 s. Then the temperature distribution throughout the glass 15 min after the strip heaters are turned on and when steady conditions are reached are determined to be (from the EES solutions disk)

15 min: T_1 = -2.4°C, T_2 = -2.4°C, T_3 = -2.5°C, T_4 = -1.8°C, T_5 = -2.0°C,

T_6 = -2.7°C, T_7 = 12.3°C, T_8 = 10.7°C, T_9 = 9.6°C

Steady-state: T_1 = -2.4°C, T_2 = -2.4°C, T_3 = -2.5°C, T_4 = -1.8°C, T_5 = -2.0°C,

T_6 = -2.7°C, T_7 = 12.3°C, T_8 = 10.7°C, T_9 = 9.6°C

Discussion Steady operating conditions are reached in about 8 min.

5-92 The formation of fog on the glass surfaces of a car is to be prevented by attaching electric resistance heaters to the inner surfaces. The temperature distribution throughout the glass 15 min after the strip heaters are turned on and also when steady conditions are reached are to be determined using the implicit method with a time step of Δ*t* = 1 min.

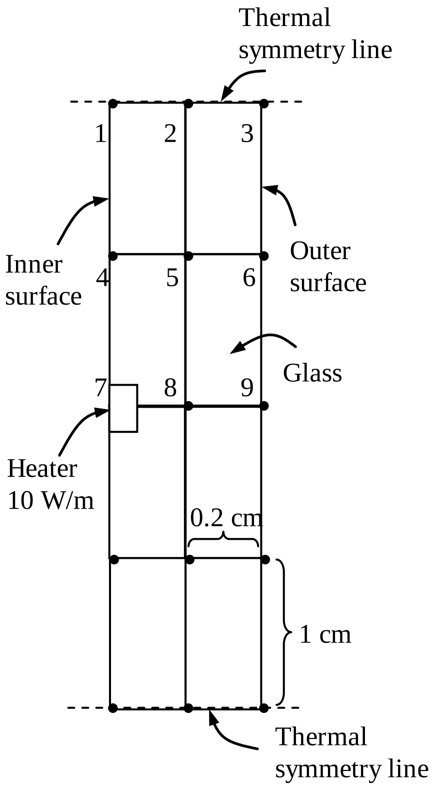
Assumptions **1** Heat transfer through the glass is given to be transient and two-dimensional. **2** Thermal conductivity is constant. **3** There is heat generation only at the inner surface, which will be treated as prescribed heat flux.

Properties The conductivity and diffusivity are given to be k = 0.84 W/m·°C and $\alpha = 0.39\times 10^{-6}\ \text{m}^2/\text{s}$.

Analysis The nodal spacing is given to be Δ*x* = 0.2 cm and Δ*y* = 1 cm. The implicit finite difference equations are determined on the basis of the energy balance for the transient case expressed as

$$\sum_{\text{All sides}} \dot{Q}^{i+1} + \dot{G}^{i+1}_{\text{element}} = \rho V_{\text{element}} C \frac{T_m^{i+1} - T_m^i}{\Delta t}$$

We consider only 9 nodes because of symmetry. Note that we do not have a square mesh in this case, and thus we will have to rely on energy balances to obtain the finite difference equations. Using energy balances, the finite difference equations for each of the 9 nodes are obtained as follows:



$$\text{Node 1: } h_i \frac{\Delta y}{2}(T_i - T_1^{i+1}) + k\frac{\Delta x}{2}\frac{T_4^{i+1} - T_1^{i+1}}{\Delta y} + k\frac{\Delta y}{2}\frac{T_2^{i+1} - T_1^{i+1}}{\Delta x} = \rho C \frac{\Delta x}{2}\frac{\Delta y}{2}\frac{T_1^{i+1} - T_1^i}{\Delta t}$$

$$\text{Node 2: } k\frac{\Delta y}{2}\frac{T_1^{i+1} - T_2^{i+1}}{\Delta x} + k\frac{\Delta y}{2}\frac{T_3^{i+1} - T_2^{i+1}}{\Delta x} + k\Delta x\frac{T_5^{i+1} - T_2^{i+1}}{\Delta y} = \rho C \Delta x\frac{\Delta y}{2}\frac{T_2^{i+1} - T_2^i}{\Delta t}$$

$$\text{Node 3: } h_o \frac{\Delta y}{2}(T_o - T_3^{i+1}) + k\frac{\Delta x}{2}\frac{T_6^{i+1} - T_3^{i+1}}{\Delta y} + k\frac{\Delta y}{2}\frac{T_2^{i+1} - T_3^{i+1}}{\Delta x} = \rho C \frac{\Delta x}{2}\frac{\Delta y}{2}\frac{T_3^{i+1} - T_3^i}{\Delta t}$$

$$\text{N4: } h_i \Delta y(T_i - T_4^{i+1}) + k\frac{\Delta x}{2}\frac{T_1^{i+1} - T_4^{i+1}}{\Delta y} + k\frac{\Delta x}{2}\frac{T_7^{i+1} - T_4^{i+1}}{\Delta y} + k\Delta y\frac{T_5^{i+1} - T_4^{i+1}}{\Delta x} = \rho C\Delta y\frac{\Delta x}{2}\frac{T_4^{i+1} - T_4^i}{\Delta t}$$

$$\text{Node 5: } k\Delta y\frac{T_4^{i+1} - T_5^{i+1}}{\Delta x} + k\Delta y\frac{T_6^{i+1} - T_5^{i+1}}{\Delta x} + k\Delta x\frac{T_8^{i+1} - T_5^{i+1}}{\Delta y} + k\Delta x\frac{T_2^{i+1} - T_5^{i+1}}{\Delta y} = \rho C\Delta x\Delta y\frac{T_5^{i+1} - T_5^i}{\Delta t}$$

$$\text{N6: } h_o \Delta y(T_i - T_6^{i+1}) + k\frac{\Delta x}{2}\frac{T_3^{i+1} - T_6^{i+1}}{\Delta y} + k\frac{\Delta x}{2}\frac{T_9^{i+1} - T_6^{i+1}}{\Delta y} + k\Delta y\frac{T_5^{i+1} - T_6^{i+1}}{\Delta x} = \rho C\Delta y\frac{\Delta x}{2}\frac{T_6^{i+1} - T_6^i}{\Delta t}$$

$$\text{Node 7: } 5\,\text{W} + h_i \frac{\Delta y}{2}(T_i - T_7^{i+1}) + k\frac{\Delta x}{2}\frac{T_4^{i+1} - T_7^{i+1}}{\Delta y} + k\frac{\Delta y}{2}\frac{T_8^{i+1} - T_7^{i+1}}{\Delta x} = \rho C \frac{\Delta x}{2}\frac{\Delta y}{2}\frac{T_7^{i+1} - T_7^i}{\Delta t}$$

$$\text{Node 8: } k\frac{\Delta y}{2}\frac{T_7^{i+1} - T_8^{i+1}}{\Delta x} + k\frac{\Delta y}{2}\frac{T_9^{i+1} - T_8^{i+1}}{\Delta x} + k\Delta x\frac{T_5^{i+1} - T_8^{i+1}}{\Delta y} = \rho C \Delta x\frac{\Delta y}{2}\frac{T_8^{i+1} - T_8^i}{\Delta t}$$

$$\text{Node 9: } h_o \frac{\Delta y}{2}(T_o - T_9^{i+1}) + k\frac{\Delta x}{2}\frac{T_6^{i+1} - T_9^{i+1}}{\Delta y} + k\frac{\Delta y}{2}\frac{T_8^{i+1} - T_9^{i+1}}{\Delta x} = \rho C \frac{\Delta x}{2}\frac{\Delta y}{2}\frac{T_9^{i+1} - T_9^i}{\Delta t}$$

where k = 0.84 W/m.°C, $\alpha = k/\rho C = 0.39\times10^{-6}\ \text{m}^2/\text{s}$, $T_i = T_o$ = -3°C h_i = 6 W/m^2.°C, h_o = 20 W/m^2.°C, Δx = 0.002 m, and Δy = 0.01 m. Taking time step to be Δt = 1 min, the temperature distribution throughout the glass 15 min after the strip heaters are turned on and when steady conditions are reached are determined to be (from the EES solutions disk)

15 min: T_1 = -2.4°C, T_2 = -2.4°C, T_3 = -2.5°C, T_4 = -1.8°C, T_5 = -2.0°C,

T_6 = -2.7°C, T_7 = 12.3°C, T_8 = 10.7°C, T_9 = 9.6°C

Steady-state: T_1 = -2.4°C, T_2 = -2.4°C, T_3 = -2.5°C, T_4 = -1.8°C, T_5 = -2.0°C,

T_6 = -2.7°C, T_7 = 12.3°C, T_8 = 10.7°C, T_9 = 9.6°C

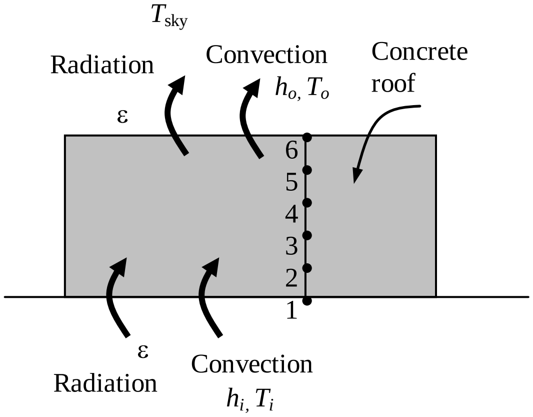
Discussion Steady operating conditions are reached in about 8 min.

5-93 The roof of a house initially at a uniform temperature is subjected to convection and radiation on both sides. The temperatures of the inner and outer surfaces of the roof at 6 am in the morning as well as the average rate of heat transfer through the roof during that night are to be determined.

Assumptions **1** Heat transfer is one-dimensional. **2** Thermal properties, heat transfer coefficients, and the indoor and outdoor temperatures are constant. **3** Radiation heat transfer is significant.

Properties The conductivity and diffusivity are given to be k = 1.4 W/m.°C and $\alpha = 0.69\times10^{-6}\ \text{m}^2/\text{s}$. The emissivity of both surfaces of the concrete roof is 0.9.

Analysis The nodal spacing is given to be Δx = 0.03 m. Then the number of nodes becomes $M = L/\Delta x + 1$ = 0.15/0.03+1 = 6. This problem involves 6 unknown nodal temperatures, and thus we need to have 6 equations. Nodes 2, 3, 4, and 5 are interior nodes, and thus for them we can use the general explicit finite difference relation expressed as



$$T_{m-1}^i - 2T_m^i + T_{m+1}^i + \frac{\dot{g}_m^i \Delta x^2}{k} = \frac{T_m^{i+1} - T_m^i}{\tau}$$

$$\rightarrow\ T_m^{i+1} = \tau(T_{m-1}^i + T_{m+1}^i) + (1-2\tau)T_m^i + \tau\frac{\dot{g}_m^i \Delta x^2}{k}$$

The finite difference equations for nodes 1 and 6 subjected to convection and radiation are obtained from an energy balance by taking the direction of all heat transfers to be towards the node under consideration:

$$\text{Node 1 (convection)}: \quad h_i(T_i - T_1^i) + k\frac{T_2^i - T_1^i}{\Delta x} + \varepsilon\sigma\left[T_{wall}^4 - (T_1^i + 273)^4\right] = \rho\frac{\Delta x}{2}C\frac{T_1^{i+1} - T_1^i}{\Delta t}$$

$$\text{Node 2 (interior)}: \quad T_2^{i+1} = \tau(T_1^i + T_3^i) + (1-2\tau)T_2^i$$

$$\text{Node 3 (interior)}: \quad T_3^{i+1} = \tau(T_2^i + T_4^i) + (1-2\tau)T_3^i$$

$$\text{Node 4 (interior)}: \quad T_4^{i+1} = \tau(T_3^i + T_5^i) + (1-2\tau)T_4^i$$

$$\text{Node 5 (interior)}: \quad T_5^{i+1} = \tau(T_4^i + T_6^i) + (1-2\tau)T_5^i$$

$$\text{Node 6 (convection)}: \quad h_o(T_0 - T_6^i) + k\frac{T_5^i - T_6^i}{\Delta x} + \varepsilon\sigma\left[T_{sky}^4 - (T_6^i + 273)^4\right] = \rho\frac{\Delta x}{2}C\frac{T_6^{i+1} - T_6^i}{\Delta t}$$

where k = 1.4 W/m.°C, $\alpha = k/\rho C = 0.69\times10^{-6}\ \text{m}^2/\text{s}$, T_i = 20°C, T_wall = 293 K, T_o = 6°C, T_sky =260 K, h_i = 5 W/m^2.°C, h_o = 12 W/m^2.°C, Δx = 0.03 m, and Δt = 5 min. Also, the mesh Fourier number is

$$\tau = \frac{\alpha\Delta t}{\Delta x^2} = \frac{(0.69\times10^{-6}\ \text{m}^2/\text{s})(300\ \text{s})}{(0.03\ \text{m})^2} = 0.230$$

Substituting this value of τ and other given quantities, the inner and outer surface temperatures of the roof after 12×(60/5) = 144 time steps (12 h) are determined to be **T_1 = 10.3°C and T_6 = -0.97°C.**

(*b*) The average temperature of the inner surface of the roof can be taken to be

$$T_{1,ave} = \frac{T_{1@6\,\text{PM}} + T_{1@6\,\text{AM}}}{2} = \frac{18+10.3}{2} = 14.15°\text{C}$$

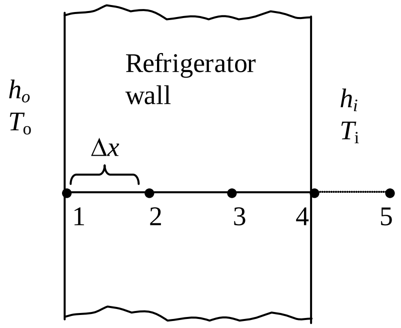
Then the average rate of heat loss through the roof that night becomes

$$\begin{aligned}\dot{Q}_{ave} &= h_i A_s(T_i - T_{1,ave}) + \varepsilon\sigma A_s\left[T_{wall}^4 - (T_1^i + 273)^4\right] \\ &= (5\ \text{W/m}^2\cdot°\text{C})(20\times20\ \text{m}^2)(20-14.15)°\text{C} + 0.9(20\times20\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(293\,\text{K})^4 - (14.15+273\,\text{K})^4] \\ &= \mathbf{23{,}360\ W}\end{aligned}$$

5-94 A refrigerator whose walls are constructed of 3-cm thick urethane insulation malfunctions, and stops running for 6 h. The temperature inside the refrigerator at the end of this 6 h period is to be determined.

Assumptions **1** Heat transfer is one-dimensional since the walls are large relative to their thickness. **2** Thermal properties, heat transfer coefficients, and the outdoor temperature are constant. **3** Radiation heat transfer is negligible. **4** The temperature of the contents of the refrigerator, including the air inside, rises uniformly during this period. **5** The local atmospheric pressure is 1 atm. **6** The space occupied by food and the corner effects are negligible. **7** Heat transfer through the bottom surface of the refrigerator is negligible.

Properties The conductivity and diffusivity are given to be k = 1.4 W/m.°C and $\alpha = 0.69\times10^{-6}\ \text{m}^2/\text{s}$. The average specific heat of food items is given to be 3.6 kJ/kg.°C. The specific heat and density of air at 1 atm and 3°C are C_p = 1.004 kJ/kg.°C and ρ = 1.29 kg/m^3 (Table A-15.



Analysis The nodal spacing is given to be Δx = 0.01 m. Then the number of nodes becomes $M = L/\Delta x + 1$ = 0.03/0.01+1 = 4. This problem involves 4 unknown nodal temperatures, and thus we need to have 4 equations. Nodes 2 and 3 are interior nodes, and thus for them we can use the general explicit finite difference relation expressed as

$$T_{m-1}^i - 2T_m^i + T_{m+1}^i + \frac{\dot{g}_m^i \Delta x^2}{k} = \frac{T_m^{i+1} - T_m^i}{\tau} \rightarrow T_m^{i+1} = \tau(T_{m-1}^i + T_{m+1}^i) + (1-2\tau)T_m^i + \tau\frac{\dot{g}_m^i \Delta x^2}{k}$$

The finite difference equations for nodes 1 and 4 subjected to convection and radiation are obtained from an energy balance by taking the direction of all heat transfers to be towards the node under consideration:

$$\text{Node 1 (convection)}: \quad h_o(T_0 - T_1^i) + k\frac{T_2^i - T_1^i}{\Delta x} = \rho\frac{\Delta x}{2}C\frac{T_1^{i+1} - T_1^i}{\Delta t}$$

$$\text{Node 2 (interior)}: \quad T_2^{i+1} = \tau(T_1^i + T_3^i) + (1-2\tau)T_2^i$$

$$\text{Node 3 (interior)}: \quad T_3^{i+1} = \tau(T_2^i + T_4^i) + (1-2\tau)T_3^i$$

$$\text{Node 4 (convection)}: \quad h_i(T_5^i - T_4^i) + k\frac{T_3^i - T_4^i}{\Delta x} = \rho\frac{\Delta x}{2}C\frac{T_4^{i+1} - T_4^i}{\Delta t}$$

where k = 0.026 W/m.°C, $\alpha = k/\rho C = 0.36\times10^{-6}\ \text{m}^2/\text{s}$, $T_5 = T_i$ = 3°C (initially), T_o = 25°C, h_i = 6 W/m^2.°C, h_o = 9 W/m^2.°C, Δx = 0.01 m, and Δt = 1 min. Also, the mesh Fourier number is

$$\tau = \frac{\alpha\Delta t}{\Delta x^2} = \frac{(0.39\times10^{-6}\ \text{m}^2/\text{s})(60\ \text{s})}{(0.01\ \text{m})^2} = 0.216$$

The volume of the refrigerator cavity and the mass of air inside are

$$V = (1.80-0.03)(0.8-0.03)(0.7-0.03) = 0.913\,\text{m}^3$$

$$m_{air} = \rho V = (1.29\ \text{kg/m}^3)(0.824\ \text{m}^3) = 1.063\ \text{kg}$$

Energy balance for the air space of the refrigerator can be expressed as

$$\text{Node 5 (refrig. air)}: \quad h_i A_i(T_4^i - T_5^i) = (mC\Delta T)_{air} + (mC\Delta T)_{food}$$

or

$$h_i A_i(T_4^i - T_5^i) = \left[(mC)_{air} + (mC)_{food}\right]\frac{T_5^{i+1} - T_5^i}{\Delta t}$$

where $$A_i = 2(1.77\times0.77) + 2(1.77\times0.67) + (0.77\times0.67) = 5.6135\,\text{m}^2$$

Substituting, temperatures of the refrigerated space after 6×60 = 360 time steps (6 h) is determined to be

$T_{in} = T_5$ =19.6°C.

Special Topic: Controlling the Numerical Error

5-96C The results obtained using a numerical method differ from the exact results obtained analytically because the results obtained by a numerical method are approximate. The difference between a numerical solution and the exact solution (the error) is primarily due to two sources: The *discretization error* (also called the *truncation* or *formulation* error) which is caused by the approximations used in the formulation of the numerical method, and the *round-off error* which is caused by the computers' representing a number by using a limited number of significant digits and continuously rounding (or chopping) off the digits it cannot retain.

5-97C The *discretization error* (also called the *truncation* or *formulation* error) is due to replacing the derivatives by differences in each step, or replacing the actual temperature distribution between two adjacent nodes by a straight line segment. The difference between the two solutions at each time step is called the *local discretization error*. The total discretization error at any step is called the *global* or *accumulated discretization error*. The local and global discretization errors are identical for the first time step.

5-98C Yes, the global (accumulated) discretization error be less than the local error during a step. The global discretization error usually increases with increasing number of steps, but the opposite may occur when the solution function changes direction frequently, giving rise to local discretization errors of opposite signs which tend to cancel each other.

5-99C The Taylor series expansion of the temperature at a specified nodal point *m* about time t_i is

$$T(x_m, t_i + \Delta t) = T(x_m, t_i) + \Delta t \frac{\partial T(x_m, t_i)}{\partial t} + \frac{1}{2}\Delta t^2 \frac{\partial^2 T(x_m, t_i)}{\partial t^2} + \cdots$$

The finite difference formulation of the time derivative at the same nodal point is expressed as

$$\frac{\partial T(x_m, t_i)}{\partial t} \cong \frac{T(x_m, t_i + \Delta t) - T(x_m, t_i)}{\Delta t} = \frac{T_m^{i+1} - T_m^i}{\Delta t} \quad \text{or} \quad T(x_m, t_i + \Delta t) \cong T(x_m, t_i) + \Delta t \frac{\partial T(x_m, t_i)}{\partial t}$$

which resembles the Taylor series expansion terminated after the first two terms.

5-100C The Taylor series expansion of the temperature at a specified nodal point *m* about time t_i is

$$T(x_m,t_i+\Delta t)=T(x_m,t_i)+\Delta t\,\frac{\partial T(x_m,t_i)}{\partial t}+\frac{1}{2}\Delta t^2\,\frac{\partial^2 T(x_m,t_i)}{\partial t^2}+\cdots$$

The finite difference formulation of the time derivative at the same nodal point is expressed as

$$\frac{\partial T(x_m,t_i)}{\partial t}\cong\frac{T(x_m,t_i+\Delta t)-T(x_m,t_i)}{\Delta t}=\frac{T_m^{i+1}-T_m^i}{\Delta t}\quad\text{or}\quad T(x_m,t_i+\Delta t)\cong T(x_m,t_i)+\Delta t\,\frac{\partial T(x_m,t_i)}{\partial t}$$

which resembles the Taylor series expansion terminated after the first two terms. Therefore, the 3rd and following terms in the Taylor series expansion represent the error involved in the finite difference approximation. For a sufficiently small time step, these terms decay rapidly as the order of derivative increases, and their contributions become smaller and smaller. The first term neglected in the Taylor series expansion is proportional to $(\Delta t)^2$, and thus the local discretization error is also proportional to $(\Delta t)^2$.

The global discretization error is proportional to the step size to Δt itself since, at the worst case, the accumulated discretization error after I time steps during a time period t_0 is $I\Delta t^2=(t_0/\Delta t)\Delta t^2=t_0\Delta t$ which is proportional to Δt.

5-101C The *round-off error* is caused by retaining a limited number of digits during calculations. It depends on the number of calculations, the method of rounding off, the type of the computer, and even the sequence of calculations. Calculations that involve the alternate addition of small and large numbers are most susceptible to round-off error.

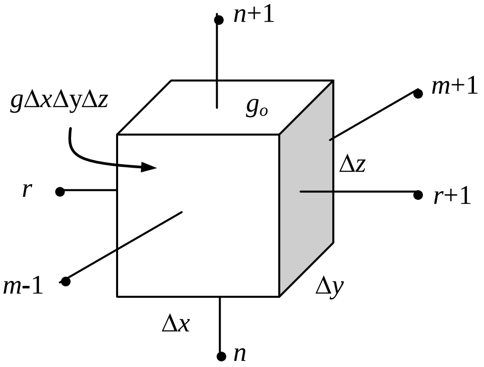
5-102C As the step size is decreased, the discretization error decreases but the round-off error increases.

5-103C The round-off error can be reduced by avoiding extremely small mess sizes (smaller than necessary to keep the discretization error in check) and sequencing the terms in the program such that the addition of small and large numbers is avoided.

5-104C A practical way of checking if the round-off error has been significant in calculations is to repeat the calculations using double precision holding the mesh size and the size of the time step constant. If the changes are not significant, we conclude that the round-off error is not a problem.

5-105C A practical way of checking if the discretization error has been significant in calculations is to start the calculations with a reasonable mesh size Δx (and time step size Δt for transient problems), based on experience, and then to repeat the calculations using a mesh size of $\Delta x/2$. If the results obtained by halving the mesh size do not differ significantly from the results obtained with the full mesh size, we conclude that the discretization error is at an acceptable level.

Review Problems



5-106 Starting with an energy balance on a volume element, the steady three-dimensional finite difference equation for a general interior node in rectangular coordinates for $T(x, y, z)$ for the case of constant thermal conductivity and uniform heat generation is to be obtained.

Analysis We consider a *volume element* of size $\Delta x\times\Delta y\times\Delta z$ centered about a general interior node (m, n, r) in a region in which heat is generated at a constant rate of $\dot{g}_0$ and the thermal conductivity k is variable. Assuming the direction of heat conduction to be *towards* the node under consideration at all surfaces, the energy balance on the volume element can be expressed as

$$\dot{Q}_{\text{cond, left}}+\dot{Q}_{\text{cond, top}}+\dot{Q}_{\text{cond, right}}+\dot{Q}_{\text{cond, bottom}}+\dot{Q}_{\text{cond, front}}+\dot{Q}_{\text{cond, back}}+\dot{G}_{\text{element}}=\frac{\Delta E_{\text{element}}}{\Delta t}=0$$

for the *steady* case. Again assuming the temperatures between the adjacent nodes to vary linearly, the energy balance relation above becomes

$$\begin{aligned}&k(\Delta y\times\Delta z)\frac{T_{m-1,n,r}-T_{m,n,r}}{\Delta x}+k(\Delta x\times\Delta z)\frac{T_{m,n+1,r}-T_{m,n,r}}{\Delta y}\\&+k(\Delta y\times\Delta z)\frac{T_{m+1,n,r}-T_{m,n,r}}{\Delta x}+k(\Delta x\times\Delta z)\frac{T_{m,n-1,r}-T_{m,n,r}}{\Delta y}\\&+k(\Delta x\times\Delta y)\frac{T_{m,n,r-1}-T_{m,n,r}}{\Delta z}+k(\Delta x\times\Delta y)\frac{T_{m,n,r+1}-T_{m,n,r}}{\Delta z}+\dot{g}_0(\Delta x\times\Delta y\times\Delta z)=0\end{aligned}$$

Dividing each term by $k\,\Delta x\times\Delta y\times\Delta z$ and simplifying gives

$$\frac{T_{m-1,n,r}-2T_{m,n,r}+T_{m+1,n,r}}{\Delta x^2}+\frac{T_{m,n-1,r}-2T_{m,n,r}+T_{m,n+1,r}}{\Delta y^2}+\frac{T_{m,n,r-1}-2T_{m,n,r}+T_{m,n,r+1}}{\Delta z^2}+\frac{\dot{g}_0}{k}=0$$

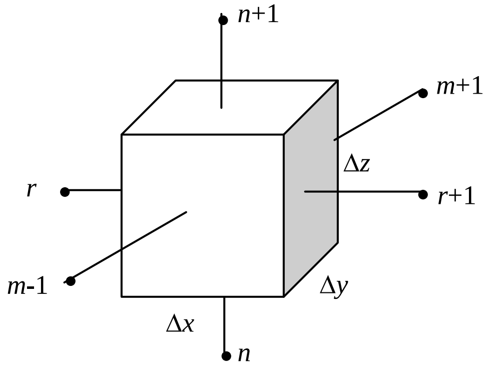
For a cubic mesh with $\Delta x = \Delta y = \Delta z = l$, and the relation above simplifies to

$$T_{m-1,n,r}+T_{m+1,n,r}+T_{m,n-1,r}+T_{m,n-1,r}+T_{m,n,r-1}+T_{m,n,r+1}-6T_{m,n,r}+\frac{\dot{g}_0 l^2}{k}=0$$

It can also be expressed in the following easy-to-remember form:

$$T_{\text{left}}+T_{\text{top}}+T_{\text{right}}+T_{\text{bottom}}+T_{\text{front}}+T_{\text{back}}-6T_{\text{node}}+\frac{\dot{g}_0 l^2}{k}=0$$

5-107 Starting with an energy balance on a volume element, the three-dimensional transient *explicit* finite difference equation for a general interior node in rectangular coordinates for $T(x, y, z, t)$ for the case of constant thermal conductivity k and no heat generation is to be obtained.



Analysis We consider a rectangular region in which heat conduction is significant in the x and y directions. There is no heat generation in the medium, and the thermal conductivity k of the medium is constant. Now we divide the x-y-z region into a *mesh* of nodal points which are spaced Δx, Δy, and Δz apart in the x, y, and z directions, respectively, and consider a general interior node (m, n, r) whose coordinates are $x = m\Delta x$, $y = n\Delta y$, are $z = r\Delta z$. Noting that the volume element centered about the general interior node (m, n, r) involves heat conduction from six sides (right, left, front, rear, top, and bottom) and expressing them at previous time step i, the transient explicit finite difference formulation for a general interior node can be expressed as

$$k(\Delta y\times\Delta z)\frac{T^i_{m-1,n,r}-T^i_{m,n,r}}{\Delta x}+k(\Delta x\times\Delta z)\frac{T^i_{m,n+1,r}-T^i_{m,n,r}}{\Delta y}+k(\Delta y\times\Delta z)\frac{T^i_{m+1,n,r}-T^i_{m,n,r}}{\Delta x}$$

$$+k(\Delta x\times\Delta z)\frac{T^i_{m,n-1,r}-T^i_{m,n,r}}{\Delta y}+k(\Delta x\times\Delta y)\frac{T^i_{m,n,r-1}-T^i_{m,n,r}}{\Delta z}+k(\Delta x\times\Delta y)\frac{T^i_{m,n,r+1}-T^i_{m,n,r}}{\Delta z}$$

$$=\rho(\Delta x\times\Delta y\times 1)C\frac{T^{i+1}_{m,n}-T^i_{m,n}}{\Delta t}$$

Taking a cubic mesh ($\Delta x = \Delta y = \Delta z = l$) and dividing each term by k gives, after simplifying,

$$T^i_{m-1,n,r}+T^i_{m+1,n,r}+T^i_{m,n+1,r}+T^i_{m,n-1,r}+T^i_{m,n,r-1}+T^i_{m,n,r+1}-6T^i_{m,n,r}=\frac{T^{i+1}_{m,n,r}-T^i_{m,n,r}}{\tau}$$

where $\alpha = k/(\rho C)$ is the thermal diffusivity of the material and $\tau = \alpha\Delta t/l^2$ is the dimensionless mesh Fourier number. It can also be expressed in terms of the temperatures at the neighboring nodes in the following easy-to-remember form:

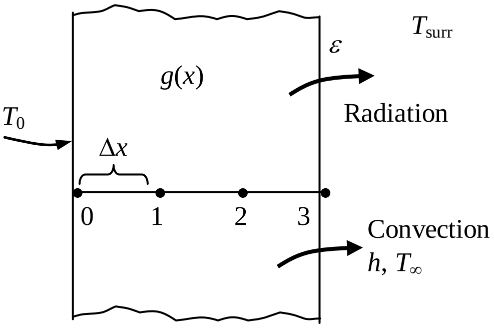
$$T^i_{\text{left}}+T^i_{\text{top}}+T^i_{\text{right}}+T^i_{\text{bottom}}+T^i_{\text{front}}+T^i_{\text{back}}-6T^i_{\text{node}}=\frac{T^{i+1}_{\text{node}}-T^i_{\text{node}}}{\tau}$$

Discussion We note that setting $T^{i+1}_{\text{node}} = T^i_{\text{node}}$ gives the steady finite difference formulation.

5-108 A plane wall with variable heat generation and constant thermal conductivity is subjected to combined convection and radiation at the right (node 3) and specified temperature at the left boundary (node 0). The finite difference formulation of the right boundary node (node 3) and the finite difference formulation for the rate of heat transfer at the left boundary (node 0) are to be determined.

Assumptions **1** Heat transfer through the wall is given to be steady and one-dimensional. **2** The thermal conductivity is given to be constant.

Analysis Using the energy balance approach and taking the direction of all heat transfers to be towards the node under consideration, the finite difference formulations become



Right boundary node (all temperatures are in K):

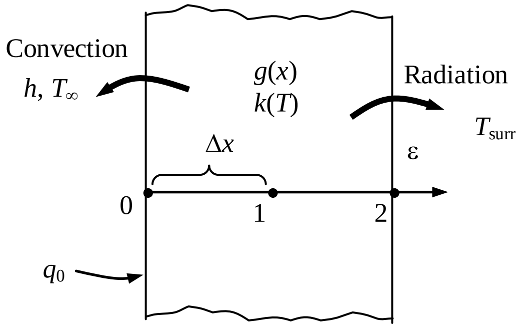
$$\varepsilon\sigma A(T_{\text{surr}}^4 - T_3^4) + hA(T_\infty - T_3) + kA\frac{T_2 - T_3}{\Delta x} + \dot{g}_3(A\Delta x/2) = 0$$

Heat transfer at left surface: $\dot{Q}_{\text{left surface}} + kA\dfrac{T_1 - T_0}{\Delta x} + \dot{g}_0(A\Delta x/2) = 0$

5-109 A plane wall with variable heat generation and variable thermal conductivity is subjected to uniform heat flux $\dot{q}_0$ and convection at the left (node 0) and radiation at the right boundary (node 2). The explicit transient finite difference formulation of the problem using the energy balance approach method is to be determined.

Assumptions **1** Heat transfer through the wall is given to be transient, and the thermal conductivity and heat generation to be variables. **2** Heat transfer is one-dimensional since the plate is large relative to its thickness. **3** Radiation from the left surface, and convection from the right surface are negligible.

Analysis Using the energy balance approach and taking the direction of all heat transfers to be towards the node under consideration, the *explicit* finite difference formulations become



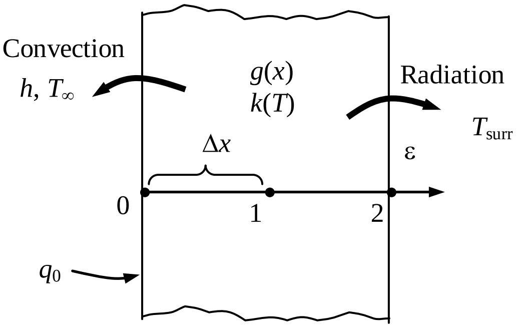
Left boundary node (node 0): $k_0^i A\dfrac{T_1^i - T_0^i}{\Delta x} + \dot{q}_0 A + hA(T_\infty - T_0^i) + \dot{g}_0^i(A\Delta x/2) = \rho A\dfrac{\Delta x}{2}C\dfrac{T_0^{i+1} - T_0^i}{\Delta t}$

Interior node (node 1): $k_1^i A\dfrac{T_0^i - T_1^i}{\Delta x} + k_1^i A\dfrac{T_2^i - T_1^i}{\Delta x} + \dot{g}_0^i(A\Delta x) = \rho A\Delta x C\dfrac{T_1^{i+1} - T_1^i}{\Delta t}$

Right boundary node (node 2):

$$k_2^i A\frac{T_1^i - T_2^i}{\Delta x} + \varepsilon\sigma A[(T_{surr}^i + 273)^4 - (T_2^i + 273)^4] + \dot{g}_2^i(A\Delta x/2) = \rho A\frac{\Delta x}{2}C\frac{T_2^{i+1} - T_2^i}{\Delta t}$$

5-110 A plane wall with variable heat generation and variable thermal conductivity is subjected to uniform heat flux $\dot{q}_0$ and convection at the left (node 0) and radiation at the right boundary (node 2). The implicit transient finite difference formulation of the problem using the energy balance approach method is to be determined.



Assumptions **1** Heat transfer through the wall is given to be transient, and the thermal conductivity and heat generation to be variables. **2** Heat transfer is one-dimensional since the plate is large relative to its thickness. **3** Radiation from the left surface, and convection from the right surface are negligible.

Analysis Using the energy balance approach and taking the direction of all heat transfers to be towards the node under consideration, the *implicit* finite difference formulations become

Left boundary node (node 0):

$$k_0^{i+1}A\frac{T_1^{i+1}-T_0^{i+1}}{\Delta x}+\dot{q}_0A+hA(T_\infty-T_0^{i+1})+\dot{g}_0^{i+1}(A\Delta x/2)=\rho A\frac{\Delta x}{2}C\frac{T_0^{i+1}-T_0^i}{\Delta t}$$

Interior node (node 1): $$k_1^{i+1}A\frac{T_0^{i+1}-T_1^{i+1}}{\Delta x}+k_1^{i+1}A\frac{T_2^{i+1}-T_1^{i+1}}{\Delta x}+\dot{g}_0^{i+1}(A\Delta x)=\rho A\Delta xC\frac{T_1^{i+1}-T_1^i}{\Delta t}$$

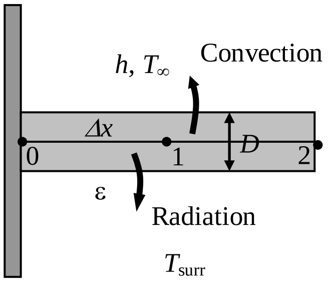
Right boundary node (node 2):

$$k_2^{i+1}A\frac{T_1^{i+1}-T_2^{i+1}}{\Delta x}+\varepsilon\sigma A[(T_{surr}^{i+1}+273)^4-(T_2^{i+1}+273)^4]+\dot{g}_2^{i+1}(A\Delta x/2)=\rho A\frac{\Delta x}{2}C\frac{T_2^{i+1}-T_2^i}{\Delta t}$$

5-111 A pin fin with convection and radiation heat transfer from its tip is considered. The complete finite difference formulation for the determination of nodal temperatures is to be obtained.

Assumptions **1** Heat transfer through the pin fin is given to be steady and one-dimensional, and the thermal conductivity to be constant. **2** Convection heat transfer coefficient and emissivity are constant and uniform.

Assumptions **1** Heat transfer through the wall is given to be steady and one-dimensional, and the thermal conductivity and heat generation to be variable. **2** Convection heat transfer at the right surface is negligible.



Analysis The nodal network consists of 3 nodes, and the base temperature T_0 at node 0 is specified. Therefore, there are two unknowns T_1 and T_2, and we need two equations to determine them. Using the energy balance approach and taking the direction of all heat transfers to be towards the node under consideration, the finite difference formulations become

Node 1 (at midpoint):

$$kA\frac{T_0-T_1}{\Delta x}+kA\frac{T_2-T_1}{\Delta x}+h(p\Delta x/2)(T_\infty-T_1)+\varepsilon\sigma A[T_{\text{surr}}^4-(T_1+273)^4]=0$$

Node 2 (at fin tip):

$$kA\frac{T_1-T_2}{\Delta x}+h(p\Delta x/2+A)(T_\infty-T_2)+\varepsilon\sigma(p\Delta x/2+A)[T_{\text{surr}}^4-(T_2+273)^4]=0$$

where $A=\pi D^2/4$ is the cross-sectional area and $p=\pi D$ is the perimeter of the fin.

5-112 Starting with an energy balance on a volume element, the two-dimensional transient *explicit* finite difference equation for a general interior node in rectangular coordinates for $T(x, y, t)$ for the case of constant thermal conductivity k and uniform heat generation $\dot{g}_0$ is to be obtained.

Analysis (See Figure 5-24 in the text)**.** We consider a rectangular region in which heat conduction is significant in the x and y directions, and consider a unit depth of $\Delta z = 1$ in the z direction. There is uniform heat generation in the medium, and the thermal conductivity k of the medium is constant. Now we divide the x-y plane of the region into a *rectangular mesh* of nodal points which are spaced Δx and Δy apart in the x and y directions, respectively, and consider a general interior node (m, n) whose coordinates are $x = m\Delta x$ and $y = n\Delta y$. Noting that the volume element centered about the general interior node (m, n) involves heat conduction from four sides (right, left, top, and bottom) and expressing them at previous time step i, the transient explicit finite difference formulation for a general interior node can be expressed as

$$k(\Delta y \times 1)\frac{T^i_{m-1,n} - T^i_{m,n}}{\Delta x} + k(\Delta x \times 1)\frac{T^i_{m,n+1} - T^i_{m,n}}{\Delta y} + k(\Delta y \times 1)\frac{T^i_{m+1,n} - T^i_{m,n}}{\Delta x} + k(\Delta x \times 1)\frac{T^i_{m,n-1} - T^i_{m,n}}{\Delta y}$$

$$+ \dot{g}_0(\Delta x \times \Delta y \times 1) = \rho(\Delta x \times \Delta y \times 1)C\frac{T^{i+1}_{m,n} - T^i_{m,n}}{\Delta t}$$

Taking a square mesh ($\Delta x = \Delta y = l$) and dividing each term by k gives, after simplifying,

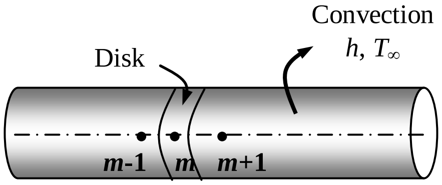
$$T^i_{m-1,n} + T^i_{m+1,n} + T^i_{m,n+1} + T^i_{m,n-1} - 4T^i_{m,n} + \frac{\dot{g}_0 l^2}{k} = \frac{T^{i+1}_{m,n} - T^i_{m,n}}{\tau}$$

where $\alpha = k/(\rho C)$ is the thermal diffusivity of the material and $\tau = \alpha\Delta t / l^2$ is the dimensionless mesh Fourier number. It can also be expressed in terms of the temperatures at the neighboring nodes in the following easy-to-remember form:

$$T^i_{\text{left}} + T^i_{\text{top}} + T^i_{\text{right}} + T^i_{\text{bottom}} - 4T^i_{\text{node}} + \frac{\dot{g}_0 l^2}{k} = \frac{T^{i+1}_{\text{node}} - T^i_{\text{node}}}{\tau}$$

Discussion We note that setting $T^{i+1}_{\text{node}} = T^i_{\text{node}}$ gives the steady finite difference formulation.

5-113 Starting with an energy balance on a disk volume element, the one-dimensional transient explicit finite difference equation for a general interior node for $T(z,t)$ in a cylinder whose side surface is subjected to convection with a convection coefficient of *h* and an ambient temperature of T_∞ for the case of constant thermal conductivity with uniform heat generation is to be obtained.



Analysis We consider transient one-dimensional heat conduction in the axial *z* direction in a cylindrical rod of constant cross-sectional area *A* with constant heat generation $\dot{g}_0$ and constant conductivity *k* with a mesh size of Δz in the *z* direction. Noting that the volume element of a general interior node *m* involves heat conduction from two sides, convection from its lateral surface, and the volume of the element is $V_{\text{element}} = A\Delta z$, the transient explicit finite difference formulation for an interior node can be expressed as

$$hA(T_\infty - T_m^i) + kA\frac{T_{m-1}^i - T_m^i}{\Delta x} + kA\frac{T_{m+1}^i - T_m^i}{\Delta x} + \dot{g}_0 A\Delta x = \rho A\Delta x C\frac{T_m^{i+1} - T_m^i}{\Delta t}$$

Canceling the surface area *A* and multiplying by Δx/k, it simplifies to

$$T_{m-1}^i - (2 + h\Delta x/k)T_m^i + T_{m+1}^i + \frac{h\Delta x}{k}T_\infty + \frac{\dot{g}_0\Delta x^2}{k} = \frac{(\Delta x)^2}{\alpha\Delta t}(T_m^{i+1} - T_m^i)$$

where $\alpha = k/(\rho C)$ is the *thermal diffusivity* of the wall material. Using the definition of the dimensionless *mesh Fourier number* $\tau = \dfrac{\alpha\Delta t}{(\Delta x)^2}$ the last equation reduces to

$$T_{m-1}^i - (2 + h\Delta x/k)T_m^i + T_{m+1}^i + \frac{h\Delta x}{k}T_\infty + \frac{\dot{g}_0\Delta x^2}{k} = \frac{T_m^{i+1} - T_m^i}{\tau}$$

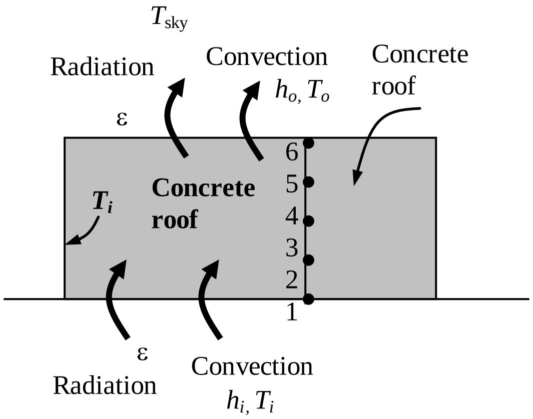
Discussion We note that setting $T_{\text{m}}^{i+1} = T_{\text{m}}^i$ gives the steady finite difference formulation.

5-114E The roof of a house initially at a uniform temperature is subjected to convection and radiation on both sides. The temperatures of the inner and outer surfaces of the roof at 6 am in the morning as well as the average rate of heat transfer through the roof during that night are to be determined.

Assumptions **1** Heat transfer is one-dimensional since the roof is large relative to its thickness. **2** Thermal properties, heat transfer coefficients, and the indoor temperatures are constant. **3** Radiation heat transfer is significant. **4** The outdoor temperature remains constant in the 4-h blocks. **5** The given time step Δt = 5 min is less than the critical time step so that the stability criteria is satisfied.

Properties The conductivity and diffusivity are given to k = 0.81 Btu/h.ft.°F and $\alpha = 7.4\times 10^{-6}\ \text{ft}^2/\text{s}$. The emissivity of both surfaces of the concrete roof is 0.9.

Analysis The nodal spacing is given to be Δx = 1 in. Then the number of nodes becomes $M = L/\Delta x + 1$ = 5/1+1 = 6. This problem involves 6 unknown nodal temperatures, and thus we need to have 6 equations. Nodes 2, 3, 4, and 5 are interior nodes, and thus for them we can use the general explicit finite difference relation expressed as



$$T_{m-1}^i - 2T_m^i + T_{m+1}^i + \frac{\dot{g}_m^i \Delta x^2}{k} = \frac{T_m^{i+1} - T_m^i}{\tau}$$

$$\rightarrow\ T_m^{i+1} = \tau(T_{m-1}^i + T_{m+1}^i) + (1-2\tau)T_m^i + \tau\frac{\dot{g}_m^i \Delta x^2}{k}$$

The finite difference equations for nodes 1 and 6 subjected to convection and radiation are obtained from an energy balance by taking the direction of all heat transfers to be towards the node under consideration:

$$\text{Node 1 (convection):}\quad h_i(T_i - T_1^i) + k\frac{T_2^i - T_1^i}{\Delta x} + \varepsilon\sigma\left[T_{wall}^4 - (T_1^i + 273)^4\right] = \rho\frac{\Delta x}{2}C\frac{T_1^{i+1} - T_1^i}{\Delta t}$$

$$\text{Node 2 (interior):}\quad T_2^{i+1} = \tau(T_1^i + T_3^i) + (1-2\tau)T_2^i$$

$$\text{Node 3 (interior):}\quad T_3^{i+1} = \tau(T_2^i + T_4^i) + (1-2\tau)T_3^i$$

$$\text{Node 4 (interior):}\quad T_4^{i+1} = \tau(T_3^i + T_5^i) + (1-2\tau)T_4^i$$

$$\text{Node 5 (interior):}\quad T_5^{i+1} = \tau(T_4^i + T_6^i) + (1-2\tau)T_5^i$$

$$\text{Node 6 (convection):}\quad h_o(T_0 - T_6^i) + k\frac{T_5^i - T_6^i}{\Delta x} + \varepsilon\sigma\left[T_{sky}^4 - (T_6^i + 273)^4\right] = \rho\frac{\Delta x}{2}C\frac{T_6^{i+1} - T_6^i}{\Delta t}$$

where k = 0.81 Btu/h.ft.°F, $\alpha = k/\rho C = 7.4\times 10^{-6}\ \text{ft}^2/\text{s}$, T_i = 70°F, T_wall = 530 R, T_sky =445 R, h_i = 0.9 Btu/h.ft^2.°F, h_o = 2.1 Btu/h.ft^2.°F, Δx = 1/12 ft, and Δt = 5 min. Also, T_o = 50°F from 6 PM to 10 PM, 42°F from 10 PM to 2 AM, and 38°F from 2 AM to 6 AM. The mesh Fourier number is

$$\tau = \frac{\alpha\Delta t}{\Delta x^2} = \frac{(7.4\times 10^{-6}\ \text{ft}^2/\text{s})(300\ \text{s})}{(1/12\ \text{ft})^2} = 0.320$$

Substituting this value of τ and other given quantities, the inner and outer surface temperatures of the roof after 12×(60/5) = 144 time steps (12 h) are determined to be **T_1 = 54.75°C and T_6 = 40.18°C**

(*b*) The average temperature of the inner surface of the roof can be taken to be

$$T_{1,ave} = \frac{T_{1\ @\ 6\ \text{PM}} + T_{1\ @\ 6\ \text{AM}}}{2} = \frac{70 + 54.75}{2} = 62.38°\,\text{F}$$

Then the average rate of heat loss through the roof that night is determined to be

$$\begin{aligned}\dot{Q}_{ave} &= h_i A(T_i - T_{1,ave}) + \varepsilon\sigma A\left[T_{wall}^4 - (T_1^i + 273)^4\right] \\ &= (0.9\ \text{Btu/h.ft}^2\cdot°\text{F})(45\times 55\ \text{ft}^2)(70 - 62.38)°\text{F} \\ &\quad + 0.9(45\times 55\ \text{ft}^2)(0.1714\times 10^{-8}\ \text{Btu/h.ft}^2\cdot\text{R}^4)[(530\ \text{R})^4 - (62.38 + 460\ \text{R})^4] \\ &= \mathbf{33{,}950\ Btu/h}\end{aligned}$$

5-115 A large pond is initially at a uniform temperature. Solar energy is incident on the pond surface at for 4 h The temperature distribution in the pond under the most favorable conditions is to be determined.

Assumptions **1** Heat transfer is one-dimensional since the pond is large relative to its depth. **2** Thermal properties, heat transfer coefficients, and the indoor temperatures are constant. **3** Radiation heat transfer is significant. **4** There are no convection currents in the water. **5** The given time step Δt = 15 min is less than the critical time step so that the stability criteria is satisfied. **6** All heat losses from the pond are negligible. **7** Heat generation due to absorption of radiation is uniform in each layer.

Properties The conductivity and diffusivity are given to be k = 0.61 W/m.°C and $\alpha = 0.15\times10^{-6}\ \text{m}^2/\text{s}$. The volumetric absorption coefficients of water are as given in the problem.

Analysis The nodal spacing is given to be Δx = 0.25 m. Then the number of nodes becomes $M = L/\Delta x + 1$ = 1/0.25+1 = 4. This problem involves 5 unknown nodal temperatures, and thus we need to have 5 equations. Nodes 2, 3, and 4 are interior nodes, and thus for them we can use the general explicit finite difference relation expressed as

$$T_{m-1}^i - 2T_m^i + T_{m+1}^i + \frac{\dot{g}_m^i \Delta x^2}{k} = \frac{T_m^{i+1} - T_m^i}{\tau} \quad \rightarrow \quad T_m^{i+1} = \tau(T_{m-1}^i + T_{m+1}^i) + (1-2\tau)T_m^i + \tau\frac{\dot{g}_m^i \Delta x^2}{k}$$

Node 0 can also be treated as an interior node by using the mirror image concept. The finite difference equation for node 4 subjected to heat flux is obtained from an energy balance by taking the direction of all heat transfers to be towards the node:

$$\text{Node 0 (insulation)}: \quad T_0^{i+1} = \tau(T_1^i + T_1^i) + (1-2\tau)T_0^i + \tau\dot{g}_0(\Delta x)^2/k$$

$$\text{Node 0 (insulation)}: \quad T_1^{i+1} = \tau(T_0^i + T_2^i) + (1-2\tau)T_1^i + \tau\dot{g}_1(\Delta x)^2/k$$

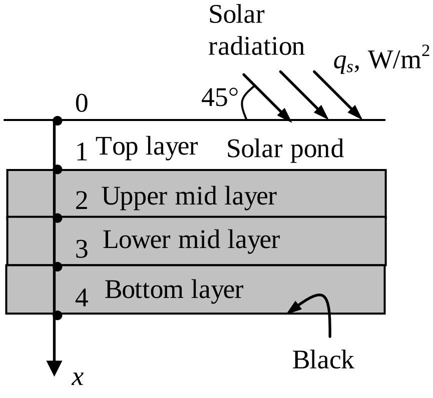
$$\text{Node 2 (interior)}: \quad T_2^{i+1} = \tau(T_1^i + T_3^i) + (1-2\tau)T_2^i + \tau\dot{g}_2(\Delta x)^2/k$$

$$\text{Node 3 (interior)}: \quad T_3^{i+1} = \tau(T_2^i + T_4^i) + (1-2\tau)T_3^i + \tau\dot{g}_3(\Delta x)^2/k$$

$$\text{Node 6 (convection)}: \quad \dot{q}_\text{b} + k\frac{T_3^i - T_4^i}{\Delta x} + \tau\dot{g}_4(\Delta x)^2/k = \rho\frac{\Delta x}{2}C\frac{T_4^{i+1} - T_4^i}{\Delta t}$$

where k = 0.61 W/m.°C, $\alpha = k/\rho C = 0.15\times10^{-6}\ \text{m}^2/\text{s}$, Δx = 0.25 m, and Δt = 15 min = 900 s. Also, the mesh Fourier number is

$$\tau = \frac{\alpha\Delta t}{\Delta x^2} = \frac{(0.15\times10^{-6}\ \text{m}^2/\text{s})(900\ \text{s})}{(0.25\ \text{m})^2} = 0.002160$$



The values of heat generation rates at the nodal points are determined as follows:

$$\dot{g}_0 = \frac{\dot{G}_0}{\text{Volume}} = \frac{0.473\times500\ \text{W}}{(1\,\text{m}^2)(0.25\,\text{m})} = 946\ \text{W/m}^3$$

$$\dot{g}_1 = \frac{\dot{G}_1}{\text{Volume}} = \frac{[(0.473+0.061)/2]\times500\ \text{W}}{(1\,\text{m}^2)(0.25\,\text{m})} = 534\ \text{W/m}^3$$

$$\dot{g}_4 = \frac{\dot{G}_4}{\text{Volume}} = \frac{0.024\times500\ \text{W}}{(1\,\text{m}^2)(0.25\,\text{m})} = 48\ \text{W/m}^3$$

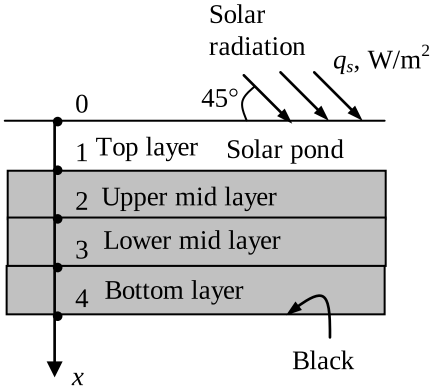
Also, the heat flux at the bottom surface is $\dot{q}_b = 0.379\times500\ \text{W/m}^2 = 4189.5\ \text{W/m}^2$. Substituting these values, the nodal temperatures in the pond after 4×(60/15) = 16 time steps (4 h) are determined to be

T_0 = 18.3°C, T_1 = 16.9°C, T_2 = 15.4°C, T_3 = 15.3°C, and T_4 = 20.2°C.

5-116 A large 1-m deep pond is initially at a uniform temperature of 15°C throughout. Solar energy is incident on the pond surface at 45° at an average rate of 500 W/m^2 for a period of 4 h The temperature distribution in the pond under the most favorable conditions is to be determined.

Assumptions **1** Heat transfer is one-dimensional since the pond is large relative to its depth. **2** Thermal properties, heat transfer coefficients, and the indoor temperatures are constant. **3** Radiation heat transfer is significant. **4** There are no convection currents in the water. **5** The given time step Δt = 15 min is less than the critical time step so that the stability criteria is satisfied. **6** All heat losses from the pond are negligible. **7** Heat generation due to absorption of radiation is uniform in each layer.

Properties The conductivity and diffusivity are given to be k = 0.61 W/m.°C and $\alpha = 0.15\times10^{-6}\ \text{m}^2/\text{s}$. The volumetric absorption coefficients of water are as given in the problem.



Analysis The nodal spacing is given to be Δx = 0.25 m. Then the number of nodes becomes $M = L/\Delta x + 1$ = 1/0.25+1 = 4. This problem involves 5 unknown nodal temperatures, and thus we need to have 5 equations. Nodes 2, 3, and 4 are interior nodes, and thus for them we can use the general explicit finite difference relation expressed as

$$T_{m-1}^i - 2T_m^i + T_{m+1}^i + \frac{\dot{g}_m^i \Delta x^2}{k} = \frac{T_m^{i+1} - T_m^i}{\tau}$$

$$\rightarrow\ T_m^{i+1} = \tau(T_{m-1}^i + T_{m+1}^i) + (1-2\tau)T_m^i + \tau\frac{\dot{g}_m^i \Delta x^2}{k}$$

Node 0 can also be treated as an interior node by using the mirror image concept. The finite difference equation for node 4 subjected to heat flux is obtained from an energy balance by taking the direction of all heat transfers to be towards the node:

$$\text{Node 0 (insulation)}: \quad T_0^{i+1} = \tau(T_1^i + T_1^i) + (1-2\tau)T_0^i + \tau\dot{g}_0(\Delta x)^2/k$$

$$\text{Node 0 (insulation)}: \quad T_1^{i+1} = \tau(T_0^i + T_2^i) + (1-2\tau)T_1^i + \tau\dot{g}_1(\Delta x)^2/k$$

$$\text{Node 2 (interior)}: \quad T_2^{i+1} = \tau(T_1^i + T_3^i) + (1-2\tau)T_2^i + \tau\dot{g}_2(\Delta x)^2/k$$

$$\text{Node 3 (interior)}: \quad T_3^{i+1} = \tau(T_2^i + T_4^i) + (1-2\tau)T_3^i + \tau\dot{g}_3(\Delta x)^2/k$$

$$\text{Node 6 (convection)}: \quad \dot{q}_\text{b} + k\frac{T_3^i - T_4^i}{\Delta x} + \tau\dot{g}_4(\Delta x)^2/k = \rho\frac{\Delta x}{2}C\frac{T_4^{i+1} - T_4^i}{\Delta t}$$

where k = 0.61 W/m.°C, $\alpha = k/\rho C = 0.15\times10^{-6}\ \text{m}^2/\text{s}$, Δx = 0.25 m, and Δt = 15 min = 900 s. Also, the mesh Fourier number is

$$\tau = \frac{\alpha\Delta t}{\Delta x^2} = \frac{(0.15\times10^{-6}\ \text{m}^2/\text{s})(900\ \text{s})}{(0.25\ \text{ft})^2} = 0.002160$$

The absorption of solar radiation is given to be $\dot{g}(x) = \dot{q}_s(0.859 - 3.415x + 6.704x^2 - 6.339x^3 + 2.278x^4)$ where $\dot{q}_s$ is the solar flux incident on the surface of the pond in W/m^2, and x is the distance form the free surface of the pond, in m. Then the values of heat generation rates at the nodal points are determined to be

Node 0 (x = 0): $\dot{g}_0 = 500(0.859 - 3.415\times0 + 6.704\times0^2 - 6.339\times0^3 + 2.278\times0^4) = 429.5\ \text{W/m}^3$

Node1(x=.25): $\dot{g}_1 = 500(0.859 - 3.415\times0.25 + 6.704\times0.25^2 - 6.339\times0.25^3 + 2.278\times0.25^4) = 167.1\ \text{W/m}^3$

Node 2 (x=0.50): $\dot{g}_2 = 500(0.859 - 3.415\times0.5 + 6.704\times0.5^2 - 6.339\times0.5^3 + 2.278\times0.5^4) = 88.8\ \text{W/m}^3$

Node3(x=.75): $\dot{g}_3 = 500(0.859 - 3.415\times0.75 + 6.704\times0.75^2 - 6.339\times0.75^3 + 2.278\times0.75^4) = 57.6\ \text{W/m}^3$

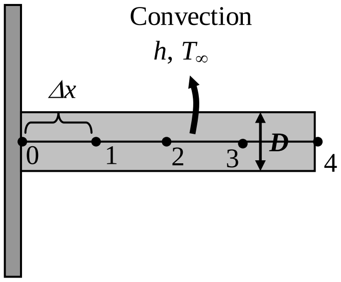
Node 4 (x = 1.00): $\dot{g}_4 = 500(0.859 - 3.415\times1 + 6.704\times1^2 - 6.339\times1^3 + 2.278\times1^4) = 43.5\ \text{W/m}^3$

Also, the heat flux at the bottom surface is $\dot{q}_b = 0.379\times500\ \text{W/m}^2 = 4189.5\ \text{W/m}^2$. Substituting these values, the nodal temperatures in the pond after 4×(60/15) = 16 time steps (4 h) are determined to be

T_0 = 16.5°C, T_1 = 15.6°C, T_2 = 15.3°C, T_3 = 15.3°C, and T_4 = 20.2°C.

5-117 A hot surface is to be cooled by aluminum pin fins. The nodal temperatures after 5 min are to be determined using the explicit finite difference method. Also to be determined is the time it takes for steady conditions to be reached.

Assumptions **1** Heat transfer through the pin fin is given to be one-dimensional. **2** The thermal properties of the fin are constant. **3** Convection heat transfer coefficient is constant and uniform. **4** Radiation heat transfer is negligible. **5** Heat loss from the fin tip is considered.



Analysis The nodal network of this problem consists of 5 nodes, and the base temperature T_0 at node 0 is specified. Therefore, there are 4 unknown nodal temperatures, and we need 4 equations to determine them. Using the energy balance approach and taking the direction of all heat transfers to be towards the node under consideration, the explicit transient finite difference formulations become

Node 1 (interior): $$hp\Delta x(T_\infty - T_1^i) + kA\frac{T_2^i - T_1^i}{\Delta x} + kA\frac{T_0 - T_1^i}{\Delta x} = \rho A\Delta xC\frac{T_1^{i+1} - T_1^i}{\Delta t}$$

Node 2 (interior): $$hp\Delta x(T_\infty - T_2^i) + kA\frac{T_3^i - T_2^i}{\Delta x} + kA\frac{T_1^i - T_2^i}{\Delta x} = \rho A\Delta xC\frac{T_2^{i+1} - T_2^i}{\Delta t}$$

Node 3 (interior): $$hp\Delta x(T_\infty - T_3^i) + kA\frac{T_4^i - T_3^i}{\Delta x} + kA\frac{T_2^i - T_3^i}{\Delta x} = \rho A\Delta xC\frac{T_3^{i+1} - T_3^i}{\Delta t}$$

Node 4 (fin tip): $$h(p\Delta x/2 + A)(T_\infty - T_4^i) + kA\frac{T_3^i - T_4^i}{\Delta x} = \rho A(\Delta x/2)C\frac{T_4^{i+1} - T_4^i}{\Delta t}$$

where $A = \pi D^2/4$ is the cross-sectional area and $p = \pi D$ is the perimeter of the fin. Also, $D = 0.008$ m, $k = 237$ W/m.°C, $\alpha = k/\rho C = 97.1\times10^{-6}\ \text{m}^2/\text{s}$, $\Delta x = 0.02$ m, $T_\infty = 30$°C, $T_0 = 120$°C $h_o = 35$ W/m^2.°C, and $\Delta t = 1$ s. Also, the mesh Fourier number is

$$\tau = \frac{\alpha\Delta t}{\Delta x^2} = \frac{(97.1\times10^{-6}\ \text{m}^2/\text{s})(1\ \text{s})}{(0.02\ \text{m})^2} = 0.24275$$

Substituting these values, the nodal temperatures along the fin after 5×60 = 300 time steps (4 h) are determined to be

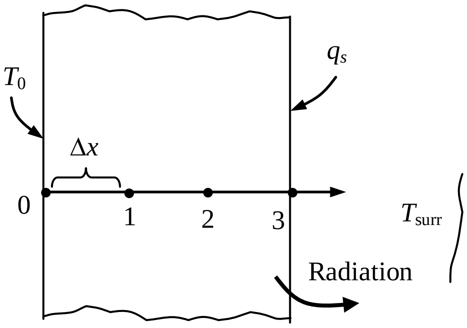
T_0 = 120°C, T_1 = 110.6°C, T_2 = 103.9°C, T_3 = 100.0°C, and T_4 = 98.5°C.

Printing the temperatures after each time step and examining them, we observe that the nodal temperatures stop changing after about 3.8 min. Thus we conclude that steady conditions are reached after **3.8 min.**

5-118E A plane wall in space is subjected to specified temperature on one side and radiation and heat flux on the other. The finite difference formulation of this problem is to be obtained, and the nodal temperatures under steady conditions are to be determined.

Assumptions **1** Heat transfer through the wall is given to be steady and one-dimensional. **2** Thermal conductivity is constant. **3** There is no heat generation. **4** There is no convection in space.

Properties The properties of the wall are given to be k=1.2 W/m·°C, ε = 0.80, and α_s = 0.45.



Analysis The nodal spacing is given to be Δx = 0.1 ft. Then the number of nodes becomes $M = L/\Delta x + 1$ = 0.3/0.1+1 = 4. The left surface temperature is given to be T_0 = 520 R = 60°F. This problem involves 3 unknown nodal temperatures, and thus we need to have 3 equations to determine them uniquely. Nodes 1 and 2 are interior nodes, and thus for them we can use the general finite difference relation expressed as

$$\frac{T_{m-1} - 2T_m + T_{m+1}}{\Delta x^2} + \frac{\dot{g}_m}{k} = 0 \rightarrow T_{m-1} - 2T_m + T_{m+1} = 0 \quad (\text{since } \dot{g} = 0), \quad \text{for } m = 1 \text{ and } 2$$

The finite difference equation for node 3 on the right surface subjected to convection and solar heat flux is obtained by applying an energy balance on the half volume element about node 3 and taking the direction of all heat transfers to be towards the node under consideration:

$$\text{Node 1 (interior):} \qquad T_0 - 2T_1 + T_2 = 0$$

$$\text{Node 2 (interior):} \qquad T_1 - 2T_2 + T_3 = 0$$

$$\text{Node 3 (right surface):} \qquad \alpha_s \dot{q}_s + \varepsilon\sigma[T_{\text{space}}^4 - (T_3 + 460)^4] + k\frac{T_2 - T_3}{\Delta x} = 0$$

where k = 1.2 Btu/h.ft.°F, ε = 0.80, α_s = 0.45, $\dot{q}_s = 300 \text{ Btu/h.ft}^2$, T_{space} = 0 R, and σ = 0.1714 Btu/h.ft^2.R ^{4} The system of 3 equations with 3 unknown temperatures constitute the finite difference formulation of the problem.

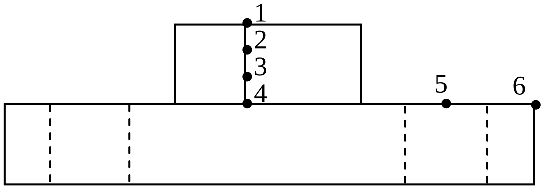
(*b*) The nodal temperatures under steady conditions are determined by solving the 3 equations above simultaneously with an equation solver to be

T_1 = 62.4°F = 522.4 R, T_2 = 64.8°F = 524.8 R, and T_3 = 67.3°F = 527.3 R

5-119 Frozen steaks are to be defrosted by placing them on a black-anodized circular aluminum plate. Using the explicit method, the time it takes to defrost the steaks is to be determined.

Assumptions **1** Heat transfer in both the steaks and the defrosting plate is one-dimensional since heat transfer from the lateral surfaces is negligible. **2** Thermal properties, heat transfer coefficients, and the surrounding air and surface temperatures remain constant during defrosting. **3** Heat transfer through the bottom surface of the plate is negligible. **4** The thermal contact resistance between the steaks and the plate is negligible. **5** Evaporation from the steaks and thus evaporative cooling is negligible. **6** The heat storage capacity of the plate is small relative to the amount of total heat transferred to the steak, and thus the heat transferred to the plate can be assumed to be transferred to the steak.

Properties The thermal properties of the steaks are ρ = 970 kg/m^3, C_p = 1.55 kJ/kg.°C, k = 1.40 W/m.°C, $\alpha = 0.93\times10^{-6}\ \text{m}^2/\text{s}$, ε = 0.95, and h_{if} = 187 kJ/kg. The thermal properties of the defrosting plate are k = 237 W/m.°C, $\alpha = 97.1\times10^{-6}\ \text{m}^2/\text{s}$, and ε = 0.90. The ρC_p (volumetric specific heat) values of the steaks and of the defrosting plate are



$$(\rho C_p)_{\text{plate}} = \frac{k}{\alpha} = \frac{237\ \text{W/m}\cdot°\text{C}}{97.1\times10^{-6}\ \text{m}^2/s} = 2441\ \text{kW/m}^3\cdot°\text{C}$$

$$(\rho C_p)_{\text{steak}} = (970\ \text{kg/m}^3)(1.55\ \text{kJ/kg}\cdot°\text{C}) = 1504\ \text{kW/m}^3\cdot°\text{C}$$

Analysis The nodal spacing is given to be Δx = 0.005 m in the steaks, and Δr = 0.0375 m in the plate. This problem involves 6 unknown nodal temperatures, and thus we need to have 6 equations. Nodes 2 and 3 are interior nodes in a plain wall, and thus for them we can use the general explicit finite difference relation expressed as

$$T_{m-1}^i - 2T_m^i + T_{m+1}^i + \frac{\dot{g}_m^i \Delta x^2}{k} = \frac{T_m^{i+1} - T_m^i}{\tau} \quad \rightarrow \quad T_m^{i+1} = \tau(T_{m-1}^i + T_{m+1}^i) + (1-2\tau)T_m^i$$

The finite difference equations for other nodes are obtained from an energy balance by taking the direction of all heat transfers to be towards the node under consideration:

Node 1: $$h(T_\infty - T_1^i) + \varepsilon_{\text{steak}}\sigma[(T_\infty + 273)^4 - (T_1^i + 273)^4] + k_{\text{steak}}\frac{T_2^i - T_1^i}{\Delta x} = (\rho C)_{\text{steak}}\frac{\Delta x}{2}\frac{T_1^{i+1} - T_1^i}{\Delta t}$$

$$\text{Node 2 (interior)}: \quad T_2^{i+1} = \tau_{\text{steak}}(T_1^i + T_3^i) + (1-2\tau_{\text{steak}})T_2^i$$

$$\text{Node 3 (interior)}: \quad T_3^{i+1} = \tau_{\text{steak}}(T_2^i + T_4^i) + (1-2\tau_{\text{steak}})T_3^i$$

Node 4:

$$\pi(r_{45}^2 - r_4^2)\{h(T_\infty - T_4^i) + \varepsilon_{\text{plate}}\sigma[(T_\infty + 273)^4 - (T_4^i + 273)^4]\} + k_{\text{steak}}(\pi r_4^2)\frac{T_3^i - T_4^i}{\Delta x}$$
$$+ k_{\text{plate}}(2\pi r_{45}\delta)\frac{T_5^i - T_4^i}{\Delta r} = [(\rho C)_{\text{steak}}(\pi r_4^2 \Delta x/2) + (\rho C)_{\text{plate}}(\pi r_{45}^2\delta)]\frac{T_4^{i+1} - T_4^i}{\Delta t}$$

Node 5:

$$2\pi r_5 \Delta r\{h(T_\infty - T_5^i) + \varepsilon_{\text{plate}}\sigma[(T_\infty + 273)^4 - (T_5^i + 273)^4]\}$$
$$+ k_{\text{plate}}(2\pi r_{56}\delta)\frac{T_6^i - T_5^i}{\Delta r} = (\rho C)_{\text{plate}}(\pi r_5^2\delta)]\frac{T_5^{i+1} - T_5^i}{\Delta t}$$

Node 6:

$$2\pi[(r_{56}+r_6)/2](\Delta r/2)\{h(T_\infty - T_6^i)+\varepsilon_{\text{plate}}\sigma[(T_\infty+273)^4-(T_6^i+273)^4]\}$$
$$+k_{\text{plate}}(2\pi r_{56}\delta)\frac{T_5^i-T_6^i}{\Delta r}=(\rho C)_{\text{plate}}[2\pi(r_{56}+r_6)/2](\Delta r/2)\delta\frac{T_6^{i+1}-T_6^i}{\Delta t}$$

where $(\rho C_p)_{\text{plate}} = 2441\text{ kW/m}^3\cdot°\text{C}$, $(\rho C_p)_{\text{steak}} = 1504\text{ kW/m}^3\cdot°\text{C}$, k_{steak} = 1.40 W/m.°C, , $\varepsilon_{\text{steak}}$ = 0.95, $\alpha_{\text{steak}} = 0.93\times10^{-6}\text{ m}^2/\text{s}$, h_{if} = 187 kJ/kg, k_{plate} = 237 W/m.°C, $\alpha_{\text{plate}} = 97.1\times10^{-6}\text{ m}^2/\text{s}$, and $\varepsilon_{\text{plate}}$ = 0.90, T_∞ = 20°C, h =12 W/m^2.°C, δ = 0.01 m, Δx = 0.005 m, Δr = 0.0375 m, and Δt = 5 s. Also, the mesh Fourier number for the steaks is

$$\tau_{\text{steak}}=\frac{\alpha\Delta t}{\Delta x^2}=\frac{(0.93\times10^{-6}\text{ m}^2/\text{s})(5\text{ s})}{(0.005\text{ m})^2}=0.186$$

The various radii are r_4 =0.075 m, r_5 =0.1125 m, r_6 =0.15 m, r_{45} = (0.075+0.1125)/2 m, and r_{56} = (0.1125+0.15)/2 m.

The total amount of heat transfer needed to defrost the steaks is

$$m_{\text{steak}}=\rho V=(970\text{ kg/m}^3)[\pi(0.075\text{ m})^2(0.015\text{ m})]=0.257\text{ kg}$$

$$Q_{\text{total, steak}}=Q_{\text{sensible}}+Q_{\text{latent}}=(mC\Delta T)_{\text{steak}}+(mh_{\text{if}})_{\text{steak}}$$
$$=(0.257\text{ kg})(1.55\text{ kJ/kg.°C})[0\text{ - (-18°C)}]+(0.257\text{ kg})(187\text{ kJ/kg})=55.2\text{ kJ}$$

The amount of heat transfer to the steak during a time step i is the sum of the heat transferred to the steak directly from its top surface, and indirectly through the plate, and is expressed as

$$Q_{\text{steak}}^i=2\pi r_5\Delta r\{h(T_\infty-T_5^i)+\varepsilon_{\text{plate}}\sigma[(T_\infty+273)^4-(T_5^i+273)^4]\}$$
$$+2\pi[(r_{56}+r_6)/2](\Delta r/2)\{h(T_\infty-T_6^i)+\varepsilon_{\text{plate}}\sigma[(T_\infty+273)^4-(T_6^i+273)^4]\}$$
$$+\pi(r_{45}^2-r_4^2)\{h(T_\infty-T_4^i)+\varepsilon_{\text{plate}}\sigma[(T_\infty+273)^4-(T_4^i+273)^4]\}$$
$$+\pi r_1^2\{h(T_\infty-T_1^i)+\varepsilon_{\text{steak}}\sigma[(T_\infty+273)^4-(T_1^i+273)^4]\}$$

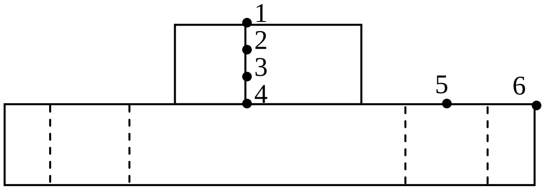
The defrosting time is determined by finding the amount of heat transfer during each time step, and adding them up until we obtain 55.2 kJ. Multiplying the number of time steps N by the time step Δt = 5 s will give the defrosting time. In this case it is determined to be

$\Delta t_{\text{defrost}}$ = NΔt = 44(5 s) = **220 s**

5-120 Frozen steaks at -18°C are to be defrosted by placing them on a 1-cm thick black-anodized circular copper defrosting plate. Using the explicit finite difference method, the time it takes to defrost the steaks is to be determined.

Assumptions **1** Heat transfer in both the steaks and the defrosting plate is one-dimensional since heat transfer from the lateral surfaces is negligible. **2** Thermal properties, heat transfer coefficients, and the surrounding air and surface temperatures remain constant during defrosting. **3** Heat transfer through the bottom surface of the plate is negligible. **4** The thermal contact resistance between the steaks and the plate is negligible. **5** Evaporation from the steaks and thus evaporative cooling is negligible. **6** The heat storage capacity of the plate is small relative to the amount of total heat transferred to the steak, and thus the heat transferred to the plate can be assumed to be transferred to the steak.

Properties The thermal properties of the steaks are ρ = 970 kg/m^3, C_p = 1.55 kJ/kg.°C, k = 1.40 W/m.°C, $\alpha = 0.93\times10^{-6}\ \text{m}^2/\text{s}$, ε = 0.95, and h_{if} = 187 kJ/kg. The thermal properties of the defrosting plate are k = 401 W/m.°C, $\alpha = 117\times10^{-6}\ \text{m}^2/\text{s}$, and ε = 0.90 (Table A-3). The ρC_p (volumetric specific heat) values of the steaks and of the defrosting plate are



$$(\rho C_p)_{\text{plate}} = (8933\ \text{kg/m}^3)(0.385\ \text{kJ/kg}\cdot°\text{C}) = 3439\ \text{kW/m}^3\cdot°\text{C}$$

$$(\rho C_p)_{\text{steak}} = (970\ \text{kg/m}^3)(1.55\ \text{kJ/kg}\cdot°\text{C}) = 1504\ \text{kW/m}^3\cdot°\text{C}$$

Analysis The nodal spacing is given to be Δx = 0.005 m in the steaks, and Δr = 0.0375 m in the plate. This problem involves 6 unknown nodal temperatures, and thus we need to have 6 equations. Nodes 2 and 3 are interior nodes in a plain wall, and thus for them we can use the general explicit finite difference relation expressed as

$$T_{m-1}^i - 2T_m^i + T_{m+1}^i + \frac{\dot{g}_m^i \Delta x^2}{k} = \frac{T_m^{i+1} - T_m^i}{\tau} \ \rightarrow\ T_m^{i+1} = \tau(T_{m-1}^i + T_{m+1}^i) + (1-2\tau)T_m^i$$

The finite difference equations for other nodes are obtained from an energy balance by taking the direction of all heat transfers to be towards the node under consideration:

Node 1: $$h(T_\infty - T_1^i) + \varepsilon_{\text{steak}}\sigma[(T_\infty+273)^4 - (T_1^i+273)^4] + k_{\text{steak}}\frac{T_2^i - T_1^i}{\Delta x} = (\rho C)_{\text{steak}}\frac{\Delta x}{2}\frac{T_1^{i+1} - T_1^i}{\Delta t}$$

Node 2 (interior): $$T_2^{i+1} = \tau_{\text{steak}}(T_1^i + T_3^i) + (1-2\tau_{\text{steak}})T_2^i$$

Node 3 (interior): $$T_3^{i+1} = \tau_{\text{steak}}(T_2^i + T_4^i) + (1-2\tau_{\text{steak}})T_3^i$$

Node 4:

$$\pi(r_{45}^2 - r_4^2)\{h(T_\infty - T_4^i) + \varepsilon_{\text{plate}}\sigma[(T_\infty+273)^4 - (T_4^i+273)^4]\} + k_{\text{steak}}(\pi r_4^2)\frac{T_3^i - T_4^i}{\Delta x}$$
$$+k_{\text{plate}}(2\pi r_{45}\delta)\frac{T_5^i - T_4^i}{\Delta r} = [(\rho C)_{\text{steak}}(\pi r_4^2\Delta x/2) + (\rho C)_{\text{plate}}(\pi r_{45}^2\delta)]\frac{T_4^{i+1} - T_4^i}{\Delta t}$$

Node 5:

$$2\pi r_5\Delta r\{h(T_\infty - T_5^i) + \varepsilon_{\text{plate}}\sigma[(T_\infty+273)^4 - (T_5^i+273)^4]\}$$
$$+k_{\text{plate}}(2\pi r_{56}\delta)\frac{T_6^i - T_5^i}{\Delta r} = (\rho C)_{\text{plate}}(\pi r_5^2\delta)]\frac{T_5^{i+1} - T_5^i}{\Delta t}$$

Node 6:

$$2\pi[(r_{56}+r_6)/2](\Delta r/2)\{h(T_\infty - T_6^i)+\varepsilon_{\text{plate}}\sigma[(T_\infty+273)^4-(T_6^i+273)^4]\}$$
$$+k_{\text{plate}}(2\pi r_{56}\delta)\frac{T_5^i-T_6^i}{\Delta r}=(\rho C)_{\text{plate}}[2\pi(r_{56}+r_6)/2](\Delta r/2)\delta\frac{T_6^{i+1}-T_6^i}{\Delta t}$$

where $(\rho C_p)_{\text{plate}} = 3439\ \text{kW/m}^3\cdot°\text{C}$, $(\rho C_p)_{\text{steak}} = 1504\ \text{kW/m}^3\cdot°\text{C}$, k_{steak} = 1.40 W/m.°C, $\varepsilon_{\text{steak}}$ = 0.95, $\alpha_{\text{steak}} = 0.93\times10^{-6}\ \text{m}^2/\text{s}$, h_{if} = 187 kJ/kg, k_{plate} = 401 W/m.°C, $\alpha_{\text{plate}} = 117\times10^{-6}\ \text{m}^2/\text{s}$, and $\varepsilon_{\text{plate}}$ = 0.90, T_∞ = 20°C, h =12 W/m^2.°C, δ = 0.01 m, Δx = 0.005 m, Δr = 0.0375 m, and Δt = 5 s. Also, the mesh Fourier number for the steaks is

$$\tau_{\text{steak}}=\frac{\alpha\Delta t}{\Delta x^2}=\frac{(0.93\times10^{-6}\ \text{m}^2/\text{s})(5\ \text{s})}{(0.005\ \text{m})^2}=0.186$$

The various radii are r_4 =0.075 m, r_5 =0.1125 m, r_6 =0.15 m, r_{45} = (0.075+0.1125)/2 m, and r_{56} = (0.1125+0.15)/2 m.

The total amount of heat transfer needed to defrost the steaks is

$$m_{\text{steak}}=\rho V=(970\ \text{kg/m}^3)[\pi(0.075\ \text{m})^2(0.015\ \text{m})]=0.257\ \text{kg}$$

$$Q_{\text{total, steak}}=Q_{\text{sensible}}+Q_{\text{latent}}=(mC\Delta T)_{\text{steak}}+(mh_{\text{if}})_{\text{steak}}$$
$$=(0.257\ \text{kg})(1.55\ \text{kJ/kg.°C})[0\text{ - }(\text{-}18°\text{C})]+(0.257\ \text{kg})(187\ \text{kJ/kg})=55.2\ \text{kJ}$$

The amount of heat transfer to the steak during a time step i is the sum of the heat transferred to the steak directly from its top surface, and indirectly through the plate, and is expressed as

$$Q_{\text{steak}}^i=2\pi r_5\Delta r\{h(T_\infty-T_5^i)+\varepsilon_{\text{plate}}\sigma[(T_\infty+273)^4-(T_5^i+273)^4]\}$$
$$+2\pi[(r_{56}+r_6)/2](\Delta r/2)\{h(T_\infty-T_6^i)+\varepsilon_{\text{plate}}\sigma[(T_\infty+273)^4-(T_6^i+273)^4]\}$$
$$+\pi(r_{45}^2-r_4^2)\{h(T_\infty-T_4^i)+\varepsilon_{\text{plate}}\sigma[(T_\infty+273)^4-(T_4^i+273)^4]\}$$
$$+\pi r_1^2\{h(T_\infty-T_1^i)+\varepsilon_{\text{steak}}\sigma[(T_\infty+273)^4-(T_1^i+273)^4]\}$$

The defrosting time is determined by finding the amount of heat transfer during each time step, and adding them up until we obtain 55.2 kJ. Multiplying the number of time steps N by the time step Δt = 5 s will give the defrosting time. In this case it is determined to be

$\Delta t_{\text{defrost}}$ = NΔt = 47(5 s) = **235 s**

5-121 ….. 5-124 Design and Essay Problems

Chapter 6
FUNDAMENTALS OF CONVECTION

Physical Mechanisms of Forced Convection

6-1C In forced convection, the fluid is forced to flow over a surface or in a tube by external means such as a pump or a fan. In natural convection, any fluid motion is caused by natural means such as the buoyancy effect that manifests itself as the rise of the warmer fluid and the fall of the cooler fluid. The convection caused by winds is natural convection for the earth, but it is forced convection for bodies subjected to the winds since for the body it makes no difference whether the air motion is caused by a fan or by the winds.

6-2C If the fluid is forced to flow over a surface, it is called external forced convection. If it is forced to flow in a tube, it is called internal forced convection. A heat transfer system can involve both internal and external convection simultaneously. Example: A pipe transporting a fluid in a windy area.

6-3C The convection heat transfer coefficient will usually be higher in forced convection since heat transfer coefficient depends on the fluid velocity, and forced convection involves higher fluid velocities.

6-4C The potato will normally cool faster by blowing warm air to it despite the smaller temperature difference in this case since the fluid motion caused by blowing enhances the heat transfer coefficient considerably.

6-5C Nusselt number is the dimensionless convection heat transfer coefficient, and it represents the enhancement of heat transfer through a fluid layer as a result of convection relative to conduction across the same fluid layer. It is defined as $Nu = \frac{hL}{k}$ where L is the characteristic length of the surface and k is the thermal conductivity of the fluid.

6-6C Heat transfer through a fluid is conduction in the absence of bulk fluid motion, and convection in the presence of it. The rate of heat transfer is higher in convection because of fluid motion. The value of the convection heat transfer coefficient depends on the fluid motion as well as the fluid properties. Thermal conductivity is a fluid property, and its value does not depend on the flow.

6-7C A fluid flow during which the density of the fluid remains nearly constant is called *incompressible flow.* A fluid whose density is practically independent of pressure (such as a liquid) is called an incompressible fluid. The flow of compressible fluid (such as air) is not necessarily compressible since the density of a compressible fluid may still remain constant during flow.

6-8 Heat transfer coefficients at different air velocities are given during air cooling of potatoes. The initial rate of heat transfer from a potato and the temperature gradient at the potato surface are to be determined.

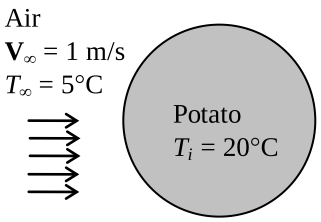
Assumptions **1** Steady operating conditions exist. **2** Potato is spherical in shape. **3** Convection heat transfer coefficient is constant over the entire surface.

Properties The thermal conductivity of the potato is given to be k = 0.49 W/m.°C.

Analysis The initial rate of heat transfer from a potato is

$$A_s = \pi D^2 = \pi(0.10\text{ m})^2 = 0.03142\text{ m}^2$$

$$\dot{Q} = hA_s(T_s - T_\infty) = (19.1\text{ W/m}^2.°\text{C})(0.03142\text{ m}^2)(20-5)°\text{C} = \mathbf{9.0\ W}$$



where the heat transfer coefficient is obtained from the table at 1 m/s velocity. The initial value of the temperature gradient at the potato surface is

$$\dot{q}_{\text{conv}} = \dot{q}_{\text{cond}} = -k\left(\frac{\partial T}{\partial r}\right)_{r=R} = h(T_s - T_\infty)$$

$$\left.\frac{\partial T}{\partial r}\right|_{r=R} = -\frac{h(T_s - T_\infty)}{k} = -\frac{(19.1\text{ W/m}^2.°\text{C})(20-5)°\text{C}}{(0.49\text{ W/m.°C})} = \mathbf{-585\ °C/m}$$

6-9 The rate of heat loss from an average man walking in still air is to be determined at different walking velocities.

Assumptions **1** Steady operating conditions exist. **2** Convection heat transfer coefficient is constant over the entire surface.

Analysis The convection heat transfer coefficients and the rate of heat losses at different walking velocities are

(*a*) $h = 8.6\mathbf{V}^{0.53} = 8.6(0.5\text{ m/s})^{0.53} = 5.956\text{ W/m}^2.°\text{C}$

$$\dot{Q} = hA_s(T_s - T_\infty) = (5.956\text{ W/m}^2.°\text{C})(1.8\text{ m}^2)(30-10)°\text{C} = \mathbf{214.4\ W}$$

(*b*) $h = 8.6\mathbf{V}^{0.53} = 8.6(1.0\text{ m/s})^{0.53} = 8.60\text{ W/m}^2.°\text{C}$

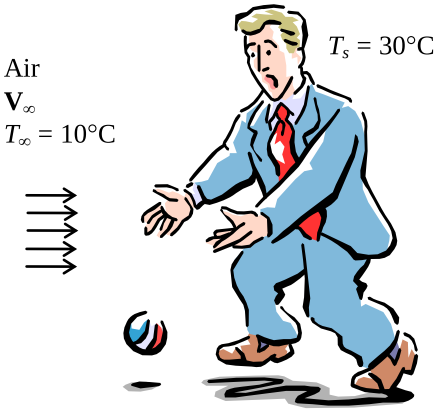
$$\dot{Q} = hA_s(T_s - T_\infty) = (8.60\text{ W/m}^2.°\text{C})(1.8\text{ m}^2)(30-10)°\text{C} = \mathbf{309.6\ W}$$

(*c*) $h = 8.6\mathbf{V}^{0.53} = 8.6(1.5\text{ m/s})^{0.53} = 10.66\text{ W/m}^2.°\text{C}$

$$\dot{Q} = hA_s(T_s - T_\infty) = (10.66\text{ W/m}^2.°\text{C})(1.8\text{ m}^2)(30-10)°\text{C} = \mathbf{383.8\ W}$$

(*d*) $h = 8.6\mathbf{V}^{0.53} = 8.6(2.0\text{ m/s})^{0.53} = 12.42\text{ W/m}^2.°\text{C}$

$$\dot{Q} = hA_s(T_s - T_\infty) = (12.42\text{ W/m}^2.°\text{C})(1.8\text{ m}^2)(30-10)°\text{C} = \mathbf{447.0\ W}$$



6-10 The rate of heat loss from an average man walking in windy air is to be determined at different wind velocities.

Assumptions **1** Steady operating conditions exist. **2** Convection heat transfer coefficient is constant over the entire surface.

Analysis The convection heat transfer coefficients and the rate of heat losses at different wind velocities are

(*a*) $h = 14.8\mathbf{V}^{0.53} = 14.8(0.5\text{ m/s})^{0.69} = 9.174\text{ W/m}^2.°\text{C}$

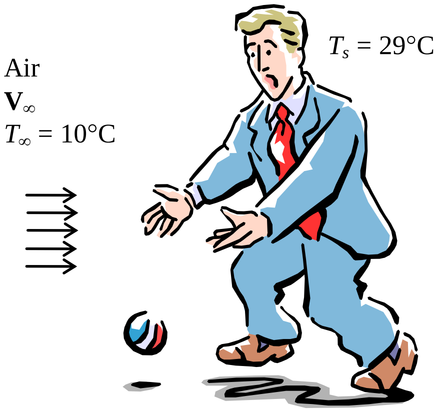
$$\dot{Q} = hA_s(T_s - T_\infty) = (9.174\text{ W/m}^2.°\text{C})(1.7\text{ m}^2)(29-10)°\text{C} = \mathbf{296.3\text{ W}}$$

(*b*) $h = 14.8\mathbf{V}^{0.53} = 14.8(1.0\text{ m/s})^{0.69} = 14.8\text{ W/m}^2.°\text{C}$

$$\dot{Q} = hA_s(T_s - T_\infty) = (14.8\text{ W/m}^2.°\text{C})(1.7\text{ m}^2)(29-10)°\text{C} = \mathbf{478.0\text{ W}}$$

(*c*) $h = 14.8\mathbf{V}^{0.53} = 14.8(1.5\text{ m/s})^{0.69} = 19.58\text{ W/m}^2.°\text{C}$

$$\dot{Q} = hA_s(T_s - T_\infty) = (19.58\text{ W/m}^2.°\text{C})(1.7\text{ m}^2)(29-10)°\text{C} = \mathbf{632.4\text{ W}}$$



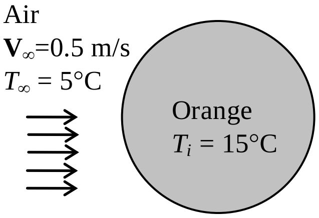
6-11 The expression for the heat transfer coefficient for air cooling of some fruits is given. The initial rate of heat transfer from an orange, the temperature gradient at the orange surface, and the value of the Nusselt number are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Orange is spherical in shape. **3** Convection heat transfer coefficient is constant over the entire surface. **4** Properties of water is used for orange.

Properties The thermal conductivity of the orange is given to be k = 0.50 W/m.°C. The thermal conductivity and the kinematic viscosity of air at the film temperature of $(T_s + T_\infty)/2 = (15+5)/2 = 10°\text{C}$ are (Table A-15)

$$k = 0.02439\text{ W/m.°C}, \qquad \upsilon = 1.426\times10^{-5}\text{ m}^2\text{/s}$$

Analysis (*a*) The Reynolds number, the heat transfer coefficient, and the initial rate of heat transfer from an orange are



$$A_s = \pi D^2 = \pi(0.07\text{ m})^2 = 0.01539\text{ m}^2$$

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{(0.5\text{ m/s})(0.07\text{ m})}{1.426\times10^{-5}\text{ m}^2\text{/s}} = 2454$$

$$h = \frac{5.05k_{air}\text{Re}^{1/3}}{D} = \frac{5.05(0.02439\text{ W/m.°C})(2454)^{1/3}}{0.07\text{ m}} = 23.73\text{ W/m}^2.°\text{C}$$

$$\dot{Q} = hA_s(T_s - T_\infty) = (23.73\text{ W/m}^2.°\text{C})(0.01539\text{ m}^2)(15-5)°\text{C} = \mathbf{3.65\text{ W}}$$

(*b*) The temperature gradient at the orange surface is determined from

$$\dot{q}_{\text{conv}} = \dot{q}_{\text{cond}} = -k\left(\frac{\partial T}{\partial r}\right)_{r=R} = h(T_s - T_\infty)$$

$$\left.\frac{\partial T}{\partial r}\right|_{r=R} = -\frac{h(T_s - T_\infty)}{k} = -\frac{(23.73\text{ W/m}^2.°\text{C})(15-5)°\text{C}}{(0.50\text{ W/m.°C})} = \mathbf{-475\text{ °C/m}}$$

(*c*) The Nusselt number is $\text{Re} = \frac{hD}{k} = \frac{(23.73\text{ W/m}^2.°\text{C})(0.07\text{ m})}{0.02439\text{ W/m.°C}} = \mathbf{68.11}$

Velocity and Thermal Boundary Layers

6-12C Viscosity is a measure of the "stickiness" or "resistance to deformation" of a fluid. It is due to the internal frictional force that develops between different layers of fluids as they are forced to move relative to each other. Viscosity is caused by the cohesive forces between the molecules in liquids, and by the molecular collisions in gases. Liquids have higher dynamic viscosities than gases.

6-13C The fluids whose shear stress is proportional to the velocity gradient are called *Newtonian fluids*. Most common fluids such as water, air, gasoline, and oils are Newtonian fluids.

6-14C A fluid in direct contact with a solid surface sticks to the surface and there is no slip. This is known as the *no-slip condition*, and it is due to the viscosity of the fluid.

6-15C For the same cruising speed, the submarine will consume much less power in air than it does in water because of the much lower viscosity of air relative to water.

6-16C (*a*) The dynamic viscosity of liquids decreases with temperature. (*b*) The dynamic viscosity of gases increases with temperature.

6-17C The fluid viscosity is responsible for the development of the velocity boundary layer. For the idealized inviscid fluids (fluids with zero viscosity), there will be no velocity boundary layer.

6-18C The Prandtl number $\mathrm{Pr} = \nu / \alpha$ is a measure of the relative magnitudes of the diffusivity of momentum (and thus the development of the velocity boundary layer) and the diffusivity of heat (and thus the development of the thermal boundary layer). The Pr is a fluid property, and thus its value is independent of the type of flow and flow geometry. The Pr changes with temperature, but not pressure.

6-19C A thermal boundary layer will not develop in flow over a surface if both the fluid and the surface are at the same temperature since there will be no heat transfer in that case.

Laminar and Turbulent Flows

6-20C A fluid motion is laminar when it involves smooth streamlines and highly ordered motion of molecules, and turbulent when it involves velocity fluctuations and highly disordered motion. The heat transfer coefficient is higher in turbulent flow.

6-21C Reynolds number is the ratio of the inertial forces to viscous forces, and it serves as a criteria for determining the flow regime. For flow over a plate of length *L* it is defined as Re = **V***L*/υ where **V** is flow velocity and υ is the kinematic viscosity of the fluid.

6-22C The friction coefficient represents the resistance to fluid flow over a flat plate. It is proportional to the drag force acting on the plate. The drag coefficient for a flat surface is equivalent to the mean friction coefficient.

6-23C In turbulent flow, it is the *turbulent eddies* due to enhanced mixing that cause the friction factor to be larger.

6-24C Turbulent viscosity μ_t is caused by turbulent eddies, and it accounts for momentum transport by turbulent eddies. It is expressed as $\tau_t = -\rho \overline{u'v'} = \mu_t \dfrac{\partial \overline{u}}{\partial y}$ where $\overline{u}$ is the mean value of velocity in the flow direction and u' and u' are the fluctuating components of velocity.

6-25C Turbulent thermal conductivity k_t is caused by turbulent eddies, and it accounts for thermal energy transport by turbulent eddies. It is expressed as $\dot{q}_t = \rho C_p \overline{v'T'} = -k_t \dfrac{\partial \overline{T}}{\partial y}$ where T' is the eddy temperature relative to the mean value, and $\dot{q}_t = \rho C_p v'T'$ the rate of thermal energy transport by turbulent eddies.

Convection Equations and Similarity Solutions

6-26C A curved surface can be treated as a flat surface if there is no flow separation and the curvature effects are negligible.

6-27C The continuity equation for steady two-dimensional flow is expressed as $\dfrac{\partial u}{\partial x} + \dfrac{\partial v}{\partial y} = 0$. When multiplied by density, the first and the second terms represent net mass fluxes in the x and y directions, respectively.

6-28C *Steady* simply means no change with time at a specified location (and thus $\partial u / \partial t = 0$), but the value of a quantity may change from one location to another (and thus $\partial u / \partial x$ and $\partial u / \partial y$ may be different from zero). Even in steady flow and thus constant mass flow rate, a fluid may accelerate. In the case of a water nozzle, for example, the velocity of water remains constant at a specified point, but it changes from inlet to the exit (water accelerates along the nozzle).

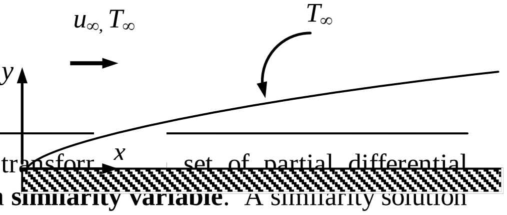
6-29C In a boundary layer during steady two-dimensional flow, the velocity component in the flow direction is much larger than that in the normal direction, and thus $u >> v$, and $\partial v / \partial x$ and $\partial v / \partial y$ are negligible. Also, *u* varies greatly with *y* in the normal direction from zero at the wall surface to nearly the free-stream value across the relatively thin boundary layer, while the variation of *u* with *x* along the flow is typically small. Therefore, $\partial u / \partial y >> \partial u / \partial x$. Similarly, if the fluid and the wall are at different temperatures and the fluid is heated or cooled during flow, heat conduction will occur primarily in the direction normal to the surface, and thus $\partial T / \partial y >> \partial T / \partial x$. That is, the velocity and temperature gradients normal to the surface are much greater than those along the surface. These simplifications are known as the **boundary layer approximations**.

6-30C For flows with low velocity and for fluids with low viscosity the viscous dissipation term in the energy equation is likely to be negligible.

6-31C For steady two-dimensional flow over an isothermal flat plate in the *x*-direction, the boundary conditions for the velocity components *u* and *v*, and the temperature *T* at the plate surface and at the edge of the boundary layer are expressed as follows:

At $y = 0$: $u(x, 0) = 0$, $v(x, 0) = 0$, $T(x, 0) = T_s$

As $y \to \infty$: $u(x, \infty) = u_\infty$, $T(x, \infty) = T_\infty$



6-32C An independent variable that makes it possible to transform set of partial differential equations into a single ordinary differential equation is called a **similarity variable**. A similarity solution is likely to exist for a set of partial differential equations if there is a function that remains unchanged (such as the non-dimensional velocity profile on a flat plate).

6-33C During steady, laminar, two-dimensional flow over an isothermal plate, the thickness of the velocity boundary layer (*a*) increase with distance from the leading edge, (*b*) decrease with free-stream velocity, and (*c*) and increase with kinematic viscosity

---

6-34C During steady, laminar, two-dimensional flow over an isothermal plate, the wall shear stress decreases with distance from the leading edge

---

6-35C A major advantage of nondimensionalizing the convection equations is the significant reduction in the number of parameters [the original problem involves 6 parameters (L, $\mathscr{V}$, T_∞, T_s, ν, α), but the nondimensionalized problem involves just 2 parameters (Re_L and Pr)]. Nondimensionalization also results in similarity parameters (such as Reynolds and Prandtl numbers) that enable us to group the results of a large number of experiments and to report them conveniently in terms of such parameters.

6-36C For steady, laminar, two-dimensional, incompressible flow with constant properties and a Prandtl number of unity and a given geometry, yes, it is correct to say that both the average friction and heat transfer coefficients depend on the Reynolds number only since $C_f = f_4(\mathrm{Re}_L)$ and $\mathrm{Nu} = g_3(\mathrm{Re}_L, \mathrm{Pr})$ from non-dimensionalized momentum and energy equations.

6-37 Parallel flow of oil between two plates is considered. The velocity and temperature distributions, the maximum temperature, and the heat flux are to be determined.

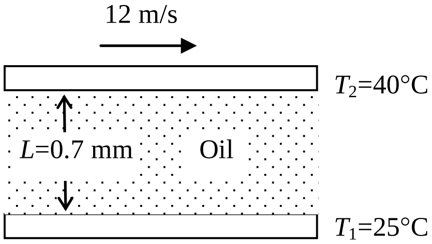
Assumptions **1** Steady operating conditions exist. **2** Oil is an incompressible substance with constant properties. **3** Body forces such as gravity are negligible. **4** The plates are large so that there is no variation in *z* direction.

Properties The properties of oil at the average temperature of (40+15)/2 = 27.5°C are (Table A-13):

$$k = 0.145 \text{ W/m-K} \quad \text{and} \quad \mu = 0.580 \text{ kg/m-s} = 0.580 \text{ N-s/m}^2$$

Analysis (*a*) We take the *x-axis* to be the flow direction, and *y* to be the normal direction. This is parallel flow between two plates, and thus $v = 0$. Then the continuity equation reduces to

Continuity: $$\frac{\partial u}{\partial x}+\frac{\partial v}{\partial y}=0 \longrightarrow \frac{\partial u}{\partial x}=0 \longrightarrow u = u(y)$$



Therefore, the *x*-component of velocity does not change in the flow direction (i.e., the velocity profile remains unchanged). Noting that $u = u(y)$, $v = 0$, and $\partial P/\partial x = 0$ (flow is maintained by the motion of the upper plate rather than the pressure gradient), the *x*-momentum equation (Eq. 6-28) reduces to

x-momentum: $$\rho\left(u\frac{\partial u}{\partial x}+v\frac{\partial u}{\partial y}\right)=\mu\frac{\partial^2 u}{\partial y^2}-\frac{\partial P}{\partial x} \longrightarrow \frac{d^2 u}{dy^2}=0$$

This is a second-order ordinary differential equation, and integrating it twice gives

$$u(y) = C_1 y + C_2$$

The fluid velocities at the plate surfaces must be equal to the velocities of the plates because of the no-slip condition. Therefore, the boundary conditions are $u(0) = 0$ and $u(L) = \mathcal{V}$, and applying them gives the velocity distribution to be

$$u(y) = \frac{y}{L}\mathrm{V}$$

Frictional heating due to viscous dissipation in this case is significant because of the high viscosity of oil and the large plate velocity. The plates are isothermal and there is no change in the flow direction, and thus the temperature depends on *y* only, $T = T(y)$. Also, $u = u(y)$ and $v = 0$. Then the energy equation with dissipation (Eqs. 6-36 and 6-37) reduce to

Energy: $$0 = k\frac{\partial^2 T}{\partial y^2}+\mu\left(\frac{\partial u}{\partial y}\right)^2 \longrightarrow k\frac{d^2 T}{dy^2}=-\mu\left(\frac{\mathrm{V}}{L}\right)^2$$

since $\partial u/\partial y = \mathrm{V}/L$. Dividing both sides by *k* and integrating twice give

$$T(y) = -\frac{\mu}{2k}\left(\frac{y}{L}\mathrm{V}\right)^2 + C_3 y + C_4$$

Applying the boundary conditions $T(0) = T_1$ and $T(L) = T_2$ gives the temperature distribution to be

$$T(y) = \frac{T_2 - T_1}{L}y + T_1 + \frac{\mu \mathrm{V}^2}{2k}\left(\frac{y}{L}-\frac{y^2}{L^2}\right)$$

(*b*) The temperature gradient is determined by differentiating *T*(*y*) with respect to *y*,

$$\frac{dT}{dy} = \frac{T_2 - T_1}{L} + \frac{\mu \mathrm{V}^2}{2kL}\left(1-2\frac{y}{L}\right)$$

The location of maximum temperature is determined by setting $dT/dy = 0$ and solving for *y*,

$$\frac{dT}{dy}=\frac{T_2-T_1}{L}+\frac{\mu V^2}{2kL}\left(1-2\frac{y}{L}\right)=0 \qquad \longrightarrow \qquad y=L\left(k\frac{T_2-T_1}{\mu V^2}+\frac{1}{2}\right)$$

The maximum temperature is the value of temperature at this y, whose numeric value is

$$y=L\left(k\frac{T_2-T_1}{\mu V^2}+\frac{1}{2}\right)=(0.0007\text{ m})\left[(0.145\text{ W/m.°C})\frac{(40-15)\text{°C}}{(0.580\text{ N.s/m}^2)(12\text{ m/s})^2}+\frac{1}{2}\right]$$
$$=0.0003804\text{ m}=\mathbf{0.3804\,mm}$$

Then

$$T_{\max}=T(0.0003804)=\frac{T_2-T_1}{L}y+T_1+\frac{\mu V^2}{2k}\left(\frac{y}{L}-\frac{y^2}{L^2}\right)$$
$$=\frac{(40-15)\text{°C}}{0.0007\text{ m}}(0.0003804\text{ m})+15\text{°C}+\frac{(0.58\text{ N}\cdot\text{s/m}^2)(12\text{ m/s})^2}{2(0.145\text{ W/m}\cdot\text{°C})}\left(\frac{0.0003804\text{ m}}{0.0007\text{ m}}-\frac{(0.0003804\text{ m})^2}{(0.0007\text{ m})^2}\right)$$
$$=\mathbf{100.0°C}$$

(c) Heat flux at the plates is determined from the definition of heat flux,

$$\dot{q}_0=-k\left.\frac{dT}{dy}\right|_{y=0}=-k\frac{T_2-T_1}{L}-k\frac{\mu V^2}{2kL}(1-0)=-k\frac{T_2-T_1}{L}-\frac{\mu V^2}{2L}$$
$$=-(0.145\text{ W/m.°C})\frac{(40-15)\text{°C}}{0.0007\text{ m}}-\frac{(0.58\text{ N}\cdot\text{s/m}^2)(12\text{ m/s})^2}{2(0.0007\text{ m})}\left(\frac{1\text{ W}}{1\text{ N}\cdot\text{m/s}}\right)=\mathbf{-6.48\times10^4\ W/m^2}$$

$$\dot{q}_L=-k\left.\frac{dT}{dy}\right|_{y=L}=-k\frac{T_2-T_1}{L}-k\frac{\mu V^2}{2kL}(1-2)=-k\frac{T_2-T_1}{L}+\frac{\mu V^2}{2L}$$
$$=-(0.145\text{ W/m.°C})\frac{(40-15)\text{°C}}{0.0007\text{ m}}+\frac{(0.58\text{ N}\cdot\text{s/m}^2)(12\text{ m/s})^2}{2(0.0007\text{ m})}\left(\frac{1\text{ W}}{1\text{ N}\cdot\text{m/s}}\right)=\mathbf{5.45\times10^4\ W/m^2}$$

Discussion A temperature rise of about 72.5°C confirms our suspicion that viscous dissipation is very significant. Calculations are done using oil properties at 27.5°C, but the oil temperature turned out to be much higher. Therefore, knowing the strong dependence of viscosity on temperature, calculations should be repeated using properties at the average temperature of about 64°C to improve accuracy.

6-38 Parallel flow of oil between two plates is considered. The velocity and temperature distributions, the maximum temperature, and the heat flux are to be determined.

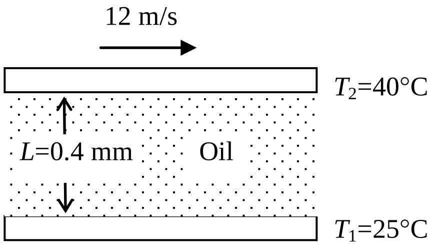
Assumptions **1** Steady operating conditions exist. **2** Oil is an incompressible substance with constant properties. **3** Body forces such as gravity are negligible. **4** The plates are large so that there is no variation in *z* direction.

Properties The properties of oil at the average temperature of (40+15)/2 = 27.5°C are (Table A-13):

$$k = 0.145 \text{ W/m-K} \quad \text{and} \quad \mu = 0.580 \text{ kg/m-s} = 0.580 \text{ N-s/m}^2$$

Analysis (*a*) We take the *x-axis* to be the flow direction, and *y* to be the normal direction. This is parallel flow between two plates, and thus $v = 0$. Then the continuity equation (Eq. 6-21) reduces to

Continuity:
$$\frac{\partial u}{\partial x}+\frac{\partial v}{\partial y}=0 \longrightarrow \frac{\partial u}{\partial x}=0 \longrightarrow u = u(y)$$



Therefore, the *x*-component of velocity does not change in the flow direction (i.e., the velocity profile remains unchanged). Noting that $u = u(y)$, $v = 0$, and $\partial P/\partial x = 0$ (flow is maintained by the motion of the upper plate rather than the pressure gradient), the *x*-momentum equation reduces to

x-momentum:
$$\rho\left(u\frac{\partial u}{\partial x}+v\frac{\partial u}{\partial y}\right)=\mu\frac{\partial^2 u}{\partial y^2}-\frac{\partial P}{\partial x} \longrightarrow \frac{d^2u}{dy^2}=0$$

This is a second-order ordinary differential equation, and integrating it twice gives

$$u(y)=C_1y+C_2$$

The fluid velocities at the plate surfaces must be equal to the velocities of the plates because of the no-slip condition. Therefore, the boundary conditions are $u(0) = 0$ and $u(L) = \mathcal{V}$, and applying them gives the velocity distribution to be

$$u(y)=\frac{y}{L}\text{V}$$

Frictional heating due to viscous dissipation in this case is significant because of the high viscosity of oil and the large plate velocity. The plates are isothermal and there is no change in the flow direction, and thus the temperature depends on *y* only, $T = T(y)$. Also, $u = u(y)$ and $v = 0$. Then the energy equation with dissipation reduces to

Energy:
$$0=k\frac{\partial^2 T}{\partial y^2}+\mu\left(\frac{\partial u}{\partial y}\right)^2 \longrightarrow k\frac{d^2T}{dy^2}=-\mu\left(\frac{\text{V}}{L}\right)^2$$

since $\partial u/\partial y = \text{V}/L$. Dividing both sides by *k* and integrating twice give

$$T(y)=-\frac{\mu}{2k}\left(\frac{y}{L}\text{V}\right)^2+C_3y+C_4$$

Applying the boundary conditions $T(0) = T_1$ and $T(L) = T_2$ gives the temperature distribution to be

$$T(y)=\frac{T_2-T_1}{L}y+T_1+\frac{\mu\text{V}^2}{2k}\left(\frac{y}{L}-\frac{y^2}{L^2}\right)$$

(*b*) The temperature gradient is determined by differentiating $T(y)$ with respect to *y*,

$$\frac{dT}{dy}=\frac{T_2-T_1}{L}+\frac{\mu\text{V}^2}{2kL}\left(1-2\frac{y}{L}\right)$$

The location of maximum temperature is determined by setting $dT/dy = 0$ and solving for *y*,

$$\frac{dT}{dy}=\frac{T_2-T_1}{L}+\frac{\mu\text{V}^2}{2kL}\left(1-2\frac{y}{L}\right)=0 \longrightarrow y=L\left(k\frac{T_2-T_1}{\mu\text{V}^2}+\frac{1}{2}\right)$$

The maximum temperature is the value of temperature at this y, whose numeric value is

$$y = L\left(k\frac{T_2 - T_1}{\mu V^2} + \frac{1}{2}\right) = (0.0004\ \mathrm{m})\left[(0.145\ \mathrm{W/m.^\circ C})\frac{(40-15)^\circ\mathrm{C}}{(0.580\ \mathrm{N.s/m^2})(12\ \mathrm{m/s})^2} + \frac{1}{2}\right]$$

$$= 0.0002174\ \mathrm{m} = \mathbf{0.2174\ mm}$$

Then

$$T_{\max} = T(0.0002174) = \frac{T_2 - T_1}{L}y + T_1 + \frac{\mu V^2}{2k}\left(\frac{y}{L} - \frac{y^2}{L^2}\right)$$

$$= \frac{(40-15)^\circ\mathrm{C}}{0.0004\ \mathrm{m}}(0.0002174\ \mathrm{m}) + 15^\circ\mathrm{C} + \frac{(0.58\ \mathrm{N\cdot s/m^2})(12\ \mathrm{m/s})^2}{2(0.145\ \mathrm{W/m\cdot ^\circ C})}\left(\frac{0.0002174\ \mathrm{m}}{0.0004\ \mathrm{m}} - \frac{(0.0002174\ \mathrm{m})^2}{(0.0004\ \mathrm{m})^2}\right)$$

$$= \mathbf{100.0^\circ C}$$

(c) Heat flux at the plates is determined from the definition of heat flux,

$$\dot{q}_0 = -k\left.\frac{dT}{dy}\right|_{y=0} = -k\frac{T_2 - T_1}{L} - k\frac{\mu V^2}{2kL}(1-0) = -k\frac{T_2 - T_1}{L} - \frac{\mu V^2}{2L}$$

$$= -(0.145\ \mathrm{W/m.^\circ C})\frac{(40-15)^\circ\mathrm{C}}{0.0004\ \mathrm{m}} - \frac{(0.58\ \mathrm{N\cdot s/m^2})(12\ \mathrm{m/s})^2}{2(0.0004\ \mathrm{m})}\left(\frac{1\ \mathrm{W}}{1\ \mathrm{N\cdot m/s}}\right) = \mathbf{-1.135\times 10^5\ W/m^2}$$

$$\dot{q}_L = -k\left.\frac{dT}{dy}\right|_{y=L} = -k\frac{T_2 - T_1}{L} - k\frac{\mu V^2}{2kL}(1-2) = -k\frac{T_2 - T_1}{L} + \frac{\mu V^2}{2L}$$

$$= -(0.145\ \mathrm{W/m.^\circ C})\frac{(40-15)^\circ\mathrm{C}}{0.0004\ \mathrm{m}} + \frac{(0.58\ \mathrm{N\cdot s/m^2})(12\ \mathrm{m/s})^2}{2(0.0004\ \mathrm{m})}\left(\frac{1\ \mathrm{W}}{1\ \mathrm{N\cdot m/s}}\right) = \mathbf{9.53\times 10^4\ W/m^2}$$

Discussion A temperature rise of about 72.5°C confirms our suspicion that viscous dissipation is very significant. Calculations are done using oil properties at 27.5°C, but the oil temperature turned out to be much higher. Therefore, knowing the strong dependence of viscosity on temperature, calculations should be repeated using properties at the average temperature of about 64°C to improve accuracy.

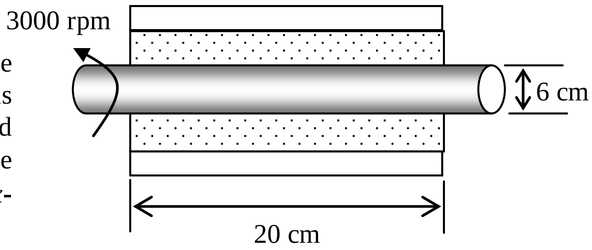
6-39 The oil in a journal bearing is considered. The velocity and temperature distributions, the maximum temperature, the rate of heat transfer, and the mechanical power wasted in oil are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Oil is an incompressible substance with constant properties. **3** Body forces such as gravity are negligible.

Properties The properties of oil at 50°C are given to be

$$k = 0.17 \text{ W/m-K} \qquad \text{and} \qquad \mu = 0.05 \text{ N-s/m}^2$$

Analysis (*a*) Oil flow in journal bearing can be approximated as parallel flow between two large plates with one plate moving and the other stationary. We take the *x-axis* to be the flow direction, and *y* to be the normal direction. This is parallel flow between two plates, and thus $v = 0$. Then the continuity equation reduces to



Continuity: $$\frac{\partial u}{\partial x}+\frac{\partial v}{\partial y}=0 \longrightarrow \frac{\partial u}{\partial x}=0 \longrightarrow u = u(y)$$

Therefore, the *x*-component of velocity does not change in the flow direction (i.e., the velocity profile remains unchanged). Noting that $u = u(y)$, $v = 0$, and $\partial P/\partial x = 0$ (flow is maintained by the motion of the upper plate rather than the pressure gradient), the *x*-momentum equation reduces to

x-momentum: $$\rho\left(u\frac{\partial u}{\partial x}+v\frac{\partial u}{\partial y}\right)=\mu\frac{\partial^2 u}{\partial y^2}-\frac{\partial P}{\partial x} \longrightarrow \frac{d^2u}{dy^2}=0$$

This is a second-order ordinary differential equation, and integrating it twice gives

$$u(y)=C_1y+C_2$$

The fluid velocities at the plate surfaces must be equal to the velocities of the plates because of the no-slip condition. Taking $x = 0$ at the surface of the bearing, the boundary conditions are $u(0) = 0$ and $u(L) = \mathcal{V}$, and applying them gives the velocity distribution to be

$$u(y)=\frac{y}{L}\mathsf{V}$$

The plates are isothermal and there is no change in the flow direction, and thus the temperature depends on *y* only, $T = T(y)$. Also, $u = u(y)$ and $v = 0$. Then the energy equation with viscous dissipation reduce to

Energy: $$0=k\frac{\partial^2 T}{\partial y^2}+\mu\left(\frac{\partial u}{\partial y}\right)^2 \longrightarrow k\frac{d^2T}{dy^2}=-\mu\left(\frac{\mathsf{V}}{L}\right)^2$$

since $\partial u/\partial y=\mathsf{V}/L$. Dividing both sides by *k* and integrating twice give

$$T(y)=-\frac{\mu}{2k}\left(\frac{y}{L}\mathsf{V}\right)^2+C_3y+C_4$$

Applying the boundary conditions $T(0) = T_0$ and $T(L) = T_0$ gives the temperature distribution to be

$$T(y)=T_0+\frac{\mu\mathsf{V}^2}{2k}\left(\frac{y}{L}-\frac{y^2}{L^2}\right)$$

The temperature gradient is determined by differentiating $T(y)$ with respect to *y*,

$$\frac{dT}{dy}=\frac{\mu\mathsf{V}^2}{2kL}\left(1-2\frac{y}{L}\right)$$

The location of maximum temperature is determined by setting $dT/dy = 0$ and solving for *y*,

$$\frac{dT}{dy}=\frac{\mu V^2}{2kL}\left(1-2\frac{y}{L}\right)=0 \qquad \longrightarrow \qquad y=\frac{L}{2}$$

Therefore, maximum temperature will occur at mid plane in the oil. The velocity and the surface area are

$$V=\pi D\dot{n}=\pi(0.06\text{ m})(3000\text{ rev/min})\left(\frac{1\text{ min}}{60\text{ s}}\right)=9.425\text{ m/s}$$

$$A=\pi DL_{bearing}=\pi(0.06\text{ m})(0.20\text{ m})=0.0377\text{ m}^2$$

The maximum temperature is

$$T_{\max}=T(L/2)=T_0+\frac{\mu V^2}{2k}\left(\frac{L/2}{L}-\frac{(L/2)^2}{L^2}\right)$$

$$=T_0+\frac{\mu V^2}{8k}=50°\text{C}+\frac{(0.05\text{ N}\cdot\text{s/m}^2)(9.425\text{ m/s})^2}{8(0.17\text{ W/m}\cdot°\text{C})}\left(\frac{1\text{ W}}{1\text{ N}\cdot\text{m/s}}\right)=\mathbf{53.3°C}$$

(*b*) The rates of heat transfer are

$$\dot{Q}_0=-kA\left.\frac{dT}{dy}\right|_{y=0}=-kA\frac{\mu V^2}{2kL}(1-0)=-A\frac{\mu V^2}{2L}$$

$$=-(0.0377\text{ m}^2)\frac{(0.05\text{ N}\cdot\text{s/m}^2)(9.425\text{ m/s})^2}{2(0.0002\text{ m})}\left(\frac{1\text{ W}}{1\text{ N}\cdot\text{m/s}}\right)=\mathbf{-419\ W}$$

$$\dot{Q}_L=-kA\left.\frac{dT}{dy}\right|_{y=L}=-kA\frac{\mu V^2}{2kL}(1-2)=A\frac{\mu V^2}{2L}=-\dot{Q}_0=\mathbf{419\ W}$$

Therefore, rates of heat transfer at the two plates are equal in magnitude but opposite in sign. The mechanical power wasted is equal to the rate of heat transfer.

$$\dot{W}_{\text{mech}}=\dot{Q}=2\times 419=\mathbf{838\ W}$$

6-40 The oil in a journal bearing is considered. The velocity and temperature distributions, the maximum temperature, the rate of heat transfer, and the mechanical power wasted in oil are to be determined.

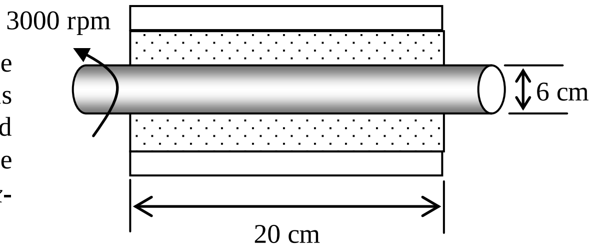
Assumptions **1** Steady operating conditions exist. **2** Oil is an incompressible substance with constant properties. **3** Body forces such as gravity are negligible.

Properties The properties of oil at 50°C are given to be

$$k = 0.17 \text{ W/m-K} \qquad \text{and} \qquad \mu = 0.05 \text{ N-s/m}^2$$

Analysis (*a*) Oil flow in journal bearing can be approximated as parallel flow between two large plates with one plate moving and the other stationary. We take the *x-axis* to be the flow direction, and *y* to be the normal direction. This is parallel flow between two plates, and thus $v = 0$. Then the continuity equation reduces to

Continuity: $\dfrac{\partial u}{\partial x}+\dfrac{\partial v}{\partial y}=0 \longrightarrow \dfrac{\partial u}{\partial x}=0 \longrightarrow u = u(y)$



Therefore, the *x*-component of velocity does not change in the flow direction (i.e., the velocity profile remains unchanged). Noting that $u = u(y)$, $v = 0$, and $\partial P/\partial x = 0$ (flow is maintained by the motion of the upper plate rather than the pressure gradient), the *x*-momentum equation reduces to

x-momentum: $\rho\left(u\dfrac{\partial u}{\partial x}+v\dfrac{\partial u}{\partial y}\right)=\mu\dfrac{\partial^2 u}{\partial y^2}-\dfrac{\partial P}{\partial x} \longrightarrow \dfrac{d^2u}{dy^2}=0$

This is a second-order ordinary differential equation, and integrating it twice gives

$$u(y) = C_1 y + C_2$$

The fluid velocities at the plate surfaces must be equal to the velocities of the plates because of the no-slip condition. Taking $x = 0$ at the surface of the bearing, the boundary conditions are $u(0) = 0$ and $u(L) = \mathcal{V}$, and applying them gives the velocity distribution to be

$$u(y) = \frac{y}{L}\mathsf{V}$$

Frictional heating due to viscous dissipation in this case is significant because of the high viscosity of oil and the large plate velocity. The plates are isothermal and there is no change in the flow direction, and thus the temperature depends on *y* only, $T = T(y)$. Also, $u = u(y)$ and $v = 0$. Then the energy equation with dissipation reduce to

Energy: $0 = k\dfrac{\partial^2 T}{\partial y^2}+\mu\left(\dfrac{\partial u}{\partial y}\right)^2 \longrightarrow k\dfrac{d^2T}{dy^2}=-\mu\left(\dfrac{\mathsf{V}}{L}\right)^2$

since $\partial u/\partial y = \mathsf{V}/L$. Dividing both sides by *k* and integrating twice give

$$\frac{dT}{dy} = -\frac{\mu}{k}\left(\frac{\mathsf{V}}{L}\right)^2 y + C_3$$

$$T(y) = -\frac{\mu}{2k}\left(\frac{y}{L}\mathsf{V}\right)^2 + C_3 y + C_4$$

Applying the two boundary conditions give

B.C. 1: $y=0$ $\qquad T(0) = T_1 \longrightarrow C_4 = T_1$

B.C. 2: $y=L$ $\qquad -k\left.\dfrac{dT}{dy}\right|_{y=L} = 0 \longrightarrow C_3 = \dfrac{\mu \mathsf{V}^2}{kL}$

Substituting the constants give the temperature distribution to be

$$T(y)=T_1+\frac{\mu \mathsf{V}^2}{kL}\left(y-\frac{y^2}{2L}\right)$$

The temperature gradient is determined by differentiating *T*(*y*) with respect to *y*,

$$\frac{dT}{dy}=\frac{\mu \mathsf{V}^2}{kL}\left(1-\frac{y}{L}\right)$$

The location of maximum temperature is determined by setting *dT*/*dy* = 0 and solving for *y*,

$$\frac{dT}{dy}=\frac{\mu \mathsf{V}^2}{kL}\left(1-\frac{y}{L}\right)=0 \longrightarrow y=L$$

This result is also known from the second boundary condition. Therefore, maximum temperature will occur at the shaft surface, for *y* = *L*. The velocity and the surface area are

$$\mathsf{V}=\pi D\dot{N}=\pi(0.06\text{ m})(3000\text{ rev/min})\left(\frac{1\text{ min}}{60\text{ s}}\right)=9.425\text{ m/s}$$

$$A=\pi DL_{bearing}=\pi(0.06\text{ m})(0.20\text{ m})=0.0377\text{ m}^2$$

The maximum temperature is

$$T_{\max}=T(L)=T_1+\frac{\mu \mathsf{V}^2}{kL}\left(L-\frac{L^2}{2L}\right)=T_1+\frac{\mu \mathsf{V}^2}{k}\left(1-\frac{1}{2}\right)=T_1+\frac{\mu \mathsf{V}^2}{2k}$$

$$=50°\text{C}+\frac{(0.05\text{ N}\cdot\text{s/m}^2)(9.425\text{ m/s})^2}{2(0.17\text{ W/m}\cdot°\text{C})}\left(\frac{1\text{ W}}{1\text{ N}\cdot\text{m/s}}\right)=\mathbf{63.1°C}$$

(*b*) The rate of heat transfer to the bearing is

$$\dot{Q}_0=-kA\left.\frac{dT}{dy}\right|_{y=0}=-kA\frac{\mu \mathsf{V}^2}{kL}(1-0)=-A\frac{\mu \mathsf{V}^2}{L}$$

$$=-(0.0377\text{ m}^2)\frac{(0.05\text{ N}\cdot\text{s/m}^2)(9.425\text{ m/s})^2}{0.0002\text{ m}}\left(\frac{1\text{ W}}{1\text{ N}\cdot\text{m/s}}\right)=\mathbf{-837\ W}$$

The rate of heat transfer to the shaft is zero. The mechanical power wasted is equal to the rate of heat transfer,

$$\dot{W}_{\text{mech}}=\dot{Q}=\mathbf{837\ W}$$

6-42 A shaft rotating in a bearing is considered. The power required to rotate the shaft is to be determined for different fluids in the gap.

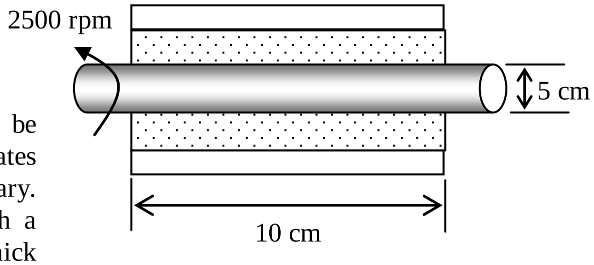
Assumptions **1** Steady operating conditions exist. **2** The fluid has constant properties. **3** Body forces such as gravity are negligible.

Properties The properties of air, water, and oil at 40°C are (Tables A-15, A-9, A-13)

Air: $\mu = 1.918\times10^{-5}$ N-s/m^2

Water: $\mu = 0.653\times10^{-3}$ N-s/m^2

Oil: $\mu = 0.212$ N-s/m^2



Analysis A shaft rotating in a bearing can be approximated as parallel flow between two large plates with one plate moving and the other stationary. Therefore, we solve this problem considering such a flow with the plates separated by a L=0.5 mm thick fluid film similar to the problem given in Example 6-1. By simplifying and solving the continuity, momentum, and energy equations it is found in Example 6-1 that

$$\dot{W}_{\text{mech}} = \dot{Q}_0 = -\dot{Q}_L = -kA\left.\frac{dT}{dy}\right|_{y=0} = -kA\frac{\mu V^2}{2kL}(1-0) = -A\frac{\mu V^2}{2L} = -A\frac{\mu V^2}{2L}$$

First, the velocity and the surface area are

$$V = \pi D\dot{N} = \pi(0.05\text{ m})(2500\text{ rev/min})\left(\frac{1\text{ min}}{60\text{ s}}\right) = 6.545\text{ m/s}$$

$$A = \pi DL_{\text{bearing}} = \pi(0.05\text{ m})(0.10\text{ m}) = 0.01571\text{ m}^2$$

(*a*) Air:

$$\dot{W}_{\text{mech}} = -A\frac{\mu V^2}{2L} = -(0.01571\text{ m}^2)\frac{(1.918\times10^{-5}\text{ N}\cdot\text{s/m}^2)(6.545\text{ m/s})^2}{2(0.0005\text{ m})}\left(\frac{1\text{ W}}{1\text{ N}\cdot\text{m/s}}\right) = \mathbf{-0.013\ W}$$

(*b*) Water:

$$\dot{W}_{\text{mech}} = \dot{Q}_0 = -A\frac{\mu V^2}{2L} = -(0.01571\text{ m}^2)\frac{(0.653\times10^{-3}\text{ N}\cdot\text{s/m}^2)(6.545\text{ m/s})^2}{2(0.0005\text{ m})}\left(\frac{1\text{ W}}{1\text{ N}\cdot\text{m/s}}\right) = \mathbf{-0.44\ W}$$

(*c*) Oil:

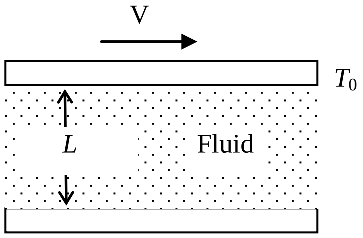
$$\dot{W}_{\text{mech}} = \dot{Q}_0 = -A\frac{\mu V^2}{2L} = -(0.01571\text{ m}^2)\frac{(0.212\text{ N}\cdot\text{s/m}^2)(6.545\text{ m/s})^2}{2(0.0005\text{ m})}\left(\frac{1\text{ W}}{1\text{ N}\cdot\text{m/s}}\right) = \mathbf{-142.7\ W}$$

6-43 The flow of fluid between two large parallel plates is considered. The relations for the maximum temperature of fluid, the location where it occurs, and heat flux at the upper plate are to be obtained.

Assumptions **1** Steady operating conditions exist. **2** The fluid has constant properties. **3** Body forces such as gravity are negligible.

Analysis We take the *x-axis* to be the flow direction, and *y* to be the normal direction. This is parallel flow between two plates, and thus $v = 0$. Then the continuity equation reduces to

Continuity: $\frac{\partial u}{\partial x}+\frac{\partial v}{\partial y}=0 \longrightarrow \frac{\partial u}{\partial x}=0 \longrightarrow u = u(y)$



Therefore, the *x*-component of velocity does not change in the flow direction (i.e., the velocity profile remains unchanged). Noting that $u = u(y)$, $v = 0$, and $\partial P/\partial x = 0$ (flow is maintained by the motion of the upper plate rather than the pressure gradient), the *x*-momentum equation reduces to

x-momentum: $\rho\left(u\frac{\partial u}{\partial x}+v\frac{\partial u}{\partial y}\right)=\mu\frac{\partial^2 u}{\partial y^2}-\frac{\partial P}{\partial x} \longrightarrow \frac{d^2u}{dy^2}=0$

This is a second-order ordinary differential equation, and integrating it twice gives

$$u(y)=C_1y+C_2$$

The fluid velocities at the plate surfaces must be equal to the velocities of the plates because of the no-slip condition. Therefore, the boundary conditions are $u(0) = 0$ and $u(L) = V$, and applying them gives the velocity distribution to be

$$u(y)=\frac{y}{L}\mathrm{V}$$

Frictional heating due to viscous dissipation in this case is significant because of the high viscosity of oil and the large plate velocity. The plates are isothermal and there is no change in the flow direction, and thus the temperature depends on *y* only, $T = T(y)$. Also, $u = u(y)$ and $v = 0$. Then the energy equation with dissipation (Eqs. 6-36 and 6-37) reduce to

Energy: $0=k\frac{\partial^2 T}{\partial y^2}+\mu\left(\frac{\partial u}{\partial y}\right)^2 \longrightarrow k\frac{d^2T}{dy^2}=-\mu\left(\frac{\mathrm{V}}{L}\right)^2$

since $\partial u/\partial y=\mathrm{V}/L$. Dividing both sides by *k* and integrating twice give

$$\frac{dT}{dy}=-\frac{\mu}{k}\left(\frac{\mathrm{V}}{L}\right)^2 y+C_3$$

$$T(y)=-\frac{\mu}{2k}\left(\frac{y}{L}\mathrm{V}\right)^2+C_3y+C_4$$

Applying the two boundary conditions give

B.C. 1: $y=0$ $\quad -k\left.\frac{dT}{dy}\right|_{y=0}=0\longrightarrow C_3=0$

B.C. 2: $y=L$ $\quad T(L)=T_0\longrightarrow C_4=T_0+\frac{\mu \mathrm{V}^2}{2k}$

Substituting the constants give the temperature distribution to be

$$T(y)=T_0+\frac{\mu\mathrm{V}^2}{2k}\left(1-\frac{y^2}{L^2}\right)$$

The temperature gradient is determined by differentiating $T(y)$ with respect to *y*,

$$\frac{dT}{dy} = \frac{-\mu V^2}{kL^2} y$$

The location of maximum temperature is determined by setting $dT/dy = 0$ and solving for y,

$$\frac{dT}{dy} = \frac{-\mu V^2}{kL^2} y = 0 \longrightarrow y = 0$$

Therefore, maximum temperature will occur at the lower plate surface, and it s value is

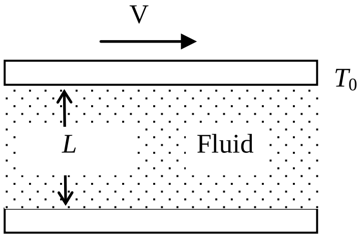
$$T_{\max} = T(0) = T_0 + \frac{\mu V^2}{2k}$$

.The heat flux at the upper plate is

$$\dot{q}_L = -k\left.\frac{dT}{dy}\right|_{y=L} = k\,\frac{\mu V^2}{kL^2} L = \frac{\mu V^2}{L}$$

6-44 The flow of fluid between two large parallel plates is considered. Using the results of Problem 6-43, a relation for the volumetric heat generation rate is to be obtained using the conduction problem, and the result is to be verified.

Assumptions **1** Steady operating conditions exist. **2** The fluid has constant properties. **3** Body forces such as gravity are negligible.



Analysis The energy equation in Prob. 6-44 was determined to be

$$k\frac{d^2T}{dy^2} = -\mu\left(\frac{V}{L}\right)^2 \qquad (1)$$

The steady one-dimensional heat conduction equation with constant heat generation is

$$\frac{d^2T}{dy^2} + \frac{\dot{g}_0}{k} = 0 \qquad (2)$$

Comparing the two equation above, the volumetric heat generation rate is determined to be

$$\dot{g}_0 = \mu\left(\frac{V}{L}\right)^2$$

Integrating Eq. (2) twice gives

$$\frac{dT}{dy} = -\frac{\dot{g}_0}{k}y + C_3$$

$$T(y) = -\frac{\dot{g}_0}{2k}y^2 + C_3 y + C_4$$

Applying the two boundary conditions give

B.C. 1: $y=0$ $\quad -k\left.\frac{dT}{dy}\right|_{y=0} = 0 \longrightarrow C_3 = 0$

B.C. 2: $y=L$ $\quad T(L) = T_0 \longrightarrow C_4 = T_0 + \frac{\dot{g}_0}{2k}L^2$

Substituting, the temperature distribution becomes

$$T(y) = T_0 + \frac{\dot{g}_0 L^2}{2k}\left(1 - \frac{y^2}{L^2}\right)$$

Maximum temperature occurs at $y = 0$, and it value is

$$T_{\max} = T(0) = T_0 + \frac{\dot{g}_0 L^2}{2k}$$

which is equivalent to the result $T_{\max} = T(0) = T_0 + \frac{\mu V^2}{2k}$ obtained in Prob. 6-43.

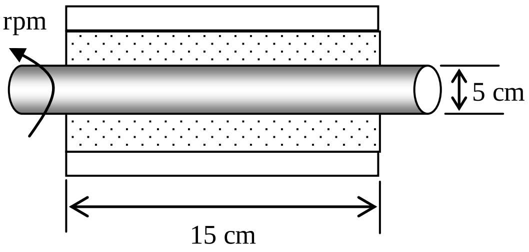
6-45 The oil in a journal bearing is considered. The bearing is cooled externally by a liquid. The surface temperature of the shaft, the rate of heat transfer to the coolant, and the mechanical power wasted are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Oil is an incompressible substance with constant properties. **3** Body forces such as gravity are negligible.

Properties The properties of oil are given to be k = 0.14 W/m-K and μ = 0.03 N-s/m^2. The thermal conductivity of bearing is given to be k = 70 W/m-K.

Analysis (*a*) Oil flow in a journal bearing can be approximated as parallel flow between two large plates with one plate moving and the other stationary. We take the *x-axis* to be the flow direction, and *y* to be the normal direction. This is parallel flow between two plates, and thus v = 0. Then the continuity equation reduces to

Continuity: $\dfrac{\partial u}{\partial x}+\dfrac{\partial v}{\partial y}=0 \longrightarrow \dfrac{\partial u}{\partial x}=0 \longrightarrow u = u(y)$



Therefore, the *x*-component of velocity does not change in the flow direction (i.e., the velocity profile remains unchanged). Noting that $u = u(y)$, $v = 0$, and $\partial P/\partial x = 0$ (flow is maintained by the motion of the upper plate rather than the pressure gradient), the *x*-momentum equation reduces to

x-momentum: $\rho\left(u\dfrac{\partial u}{\partial x}+v\dfrac{\partial u}{\partial y}\right)=\mu\dfrac{\partial^2 u}{\partial y^2}-\dfrac{\partial P}{\partial x} \longrightarrow \dfrac{d^2u}{dy^2}=0$

This is a second-order ordinary differential equation, and integrating it twice gives

$$u(y)=C_1y+C_2$$

The fluid velocities at the plate surfaces must be equal to the velocities of the plates because of the no-slip condition. Therefore, the boundary conditions are $u(0) = 0$ and $u(L) = \mathcal{V}$, and applying them gives the velocity distribution to be

$$u(y)=\frac{y}{L}\mathcal{V}$$

where

$$\mathcal{V}=\pi D\dot{n}=\pi(0.05\,\text{m})(4500\,\text{rev/min})\left(\frac{1\,\text{min}}{60\,\text{s}}\right)=11.78\,\text{m/s}$$

The plates are isothermal and there is no change in the flow direction, and thus the temperature depends on *y* only, $T = T(y)$. Also, $u = u(y)$ and $v = 0$. Then the energy equation with viscous dissipation reduces to

Energy: $0=k\dfrac{\partial^2T}{\partial y^2}+\mu\left(\dfrac{\partial u}{\partial y}\right)^2 \longrightarrow k\dfrac{d^2T}{dy^2}=-\mu\left(\dfrac{\mathcal{V}}{L}\right)^2$

since $\partial u/\partial y=\mathcal{V}/L$. Dividing both sides by *k* and integrating twice give

$$\frac{dT}{dy}=-\frac{\mu}{k}\left(\frac{\mathcal{V}}{L}\right)^2y+C_3$$

$$T(y)=-\frac{\mu}{2k}\left(\frac{y}{L}\mathcal{V}\right)^2+C_3y+C_4$$

Applying the two boundary conditions give

B.C. 1: y=0 $\quad -k\left.\dfrac{dT}{dy}\right|_{y=0}=0 \longrightarrow C_3=0$

B.C. 2: $y=L$ $\quad T(L)=T_0 \longrightarrow C_4 = T_0 + \dfrac{\mu V^2}{2k}$

Substituting the constants give the temperature distribution to be

$$T(y) = T_0 + \frac{\mu V^2}{2k}\left(1 - \frac{y^2}{L^2}\right)$$

The temperature gradient is determined by differentiating *T*(*y*) with respect to *y*,

$$\frac{dT}{dy} = \frac{-\mu V^2}{kL^2}y$$

.The heat flux at the upper surface is

$$\dot{q}_L = -k\left.\frac{dT}{dy}\right|_{y=L} = k\frac{\mu V^2}{kL^2}L = \frac{\mu V^2}{L}$$

Noting that heat transfer along the shaft is negligible, all the heat generated in the oil is transferred to the shaft, and the rate of heat transfer is

$$\dot{Q} = A_s\dot{q}_L = (\pi DW)\frac{\mu V^2}{L} = \pi(0.05\text{ m})(0.15\text{ m})\frac{(0.03\text{ N}\cdot\text{s/m}^2)(11.78\text{ m/s})^2}{0.0006\text{ m}} = \mathbf{163.5\ W}$$

(b) This is equivalent to the rate of heat transfer through the cylindrical sleeve by conduction, which is expressed as

$$\dot{Q} = k\frac{2\pi W(T_0 - T_s)}{\ln(D_0/D)} \quad \rightarrow \ (70\text{ W/m}\cdot{}^\circ\text{C})\frac{2\pi(0.15\text{ m})(T_0 - 40^\circ\text{C})}{\ln(8/5)} = 163.5\text{ W}$$

which gives the surface temperature of the shaft to be

T_o = **41.2°C**

(c) The mechanical power wasted by the viscous dissipation in oil is equivalent to the rate of heat generation,

$$\dot{W}_{lost} = \dot{Q} = \mathbf{163.5\ W}$$

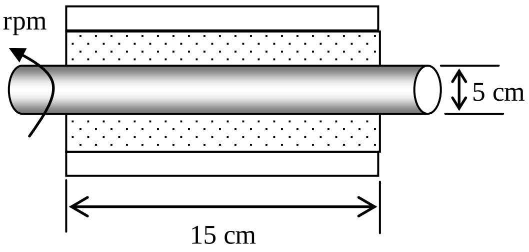
6-46 The oil in a journal bearing is considered. The bearing is cooled externally by a liquid. The surface temperature of the shaft, the rate of heat transfer to the coolant, and the mechanical power wasted are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Oil is an incompressible substance with constant properties. **3** Body forces such as gravity are negligible.

Properties The properties of oil are given to be k = 0.14 W/m-K and μ = 0.03 N-s/m^2. The thermal conductivity of bearing is given to be k = 70 W/m-K.

Analysis (*a*) Oil flow in a journal bearing can be approximated as parallel flow between two large plates with one plate moving and the other stationary. We take the *x-axis* to be the flow direction, and y to be the normal direction. This is parallel flow between two plates, and thus v = 0. Then the continuity equation reduces to

Continuity: $$\frac{\partial u}{\partial x}+\frac{\partial v}{\partial y}=0 \longrightarrow \frac{\partial u}{\partial x}=0 \longrightarrow u = u(y)$$



Therefore, the x-component of velocity does not change in the flow direction (i.e., the velocity profile remains unchanged). Noting that $u = u(y)$, $v = 0$, and $\partial P/\partial x = 0$ (flow is maintained by the motion of the upper plate rather than the pressure gradient), the x-momentum equation reduces to

x-momentum: $$\rho\left(u\frac{\partial u}{\partial x}+v\frac{\partial u}{\partial y}\right)=\mu\frac{\partial^2 u}{\partial y^2}-\frac{\partial P}{\partial x} \longrightarrow \frac{d^2 u}{dy^2}=0$$

This is a second-order ordinary differential equation, and integrating it twice gives

$$u(y)=C_1 y+C_2$$

The fluid velocities at the plate surfaces must be equal to the velocities of the plates because of the no-slip condition. Therefore, the boundary conditions are $u(0) = 0$ and $u(L) = \mathcal{V}$, and applying them gives the velocity distribution to be

$$u(y)=\frac{y}{L}\mathrm{V}$$

where

$$\mathrm{V}=\pi D\dot{n}=\pi(0.05\,\mathrm{m})(4500\,\mathrm{rev/min})\left(\frac{1\,\mathrm{min}}{60\,\mathrm{s}}\right)=11.78\,\mathrm{m/s}$$

The plates are isothermal and there is no change in the flow direction, and thus the temperature depends on y only, $T = T(y)$. Also, $u = u(y)$ and $v = 0$. Then the energy equation with viscous dissipation reduces to

Energy: $$0=k\frac{\partial^2 T}{\partial y^2}+\mu\left(\frac{\partial u}{\partial y}\right)^2 \longrightarrow k\frac{d^2 T}{dy^2}=-\mu\left(\frac{\mathrm{V}}{L}\right)^2$$

since $\partial u/\partial y=\mathcal{V}/L$. Dividing both sides by k and integrating twice give

$$\frac{dT}{dy}=-\frac{\mu}{k}\left(\frac{\mathrm{V}}{L}\right)^2 y+C_3$$

$$T(y)=-\frac{\mu}{2k}\left(\frac{y}{L}\mathrm{V}\right)^2+C_3 y+C_4$$

Applying the two boundary conditions give

B.C. 1: y=0 $$-k\left.\frac{dT}{dy}\right|_{y=0}=0\longrightarrow C_3=0$$

B.C. 2: $y=L$ $\quad T(L)=T_0 \longrightarrow C_4 = T_0 + \dfrac{\mu V^2}{2k}$

Substituting the constants give the temperature distribution to be

$$T(y)=T_0+\frac{\mu V^2}{2k}\left(1-\frac{y^2}{L^2}\right)$$

The temperature gradient is determined by differentiating $T(y)$ with respect to y,

$$\frac{dT}{dy}=\frac{-\mu V^2}{kL^2}y$$

.The heat flux at the upper surface is

$$\dot{q}_L=-k\frac{dT}{dy}\bigg|_{y=L}=k\frac{\mu V^2}{kL^2}L=\frac{\mu V^2}{L}$$

Noting that heat transfer along the shaft is negligible, all the heat generated in the oil is transferred to the shaft, and the rate of heat transfer is

$$\dot{Q}=A_s\dot{q}_L=(\pi DW)\frac{\mu V^2}{L}=\pi(0.05\,\text{m})(0.15\,\text{m})\frac{(0.03\,\text{N}\cdot\text{s/m}^2)(11.78\,\text{m/s})^2}{0.001\,\text{m}}=\mathbf{98.1\,W}$$

(b) This is equivalent to the rate of heat transfer through the cylindrical sleeve by conduction, which is expressed as

$$\dot{Q}=k\frac{2\pi W(T_0-T_s)}{\ln(D_0/D)}\quad\rightarrow\ (70\,\text{W/m}\cdot{}^\circ\text{C})\frac{2\pi(0.15\,\text{m})(T_0\text{ - }40^\circ\text{C})}{\ln(8/5)}=98.1\,\text{W}$$

which gives the surface temperature of the shaft to be

T_o = **40.7°C**

(c) The mechanical power wasted by the viscous dissipation in oil is equivalent to the rate of heat generation,

$$\dot{W}_{lost}=\dot{Q}=\mathbf{98.1\,W}$$

Momentum and Heat Transfer Analogies

6-47C Reynolds analogy is expressed as $C_{f,x}\dfrac{\text{Re}_L}{2} = \text{Nu}_x$. It allows us to calculate the heat transfer coefficient from a knowledge of friction coefficient. It is limited to flow of fluids with a Prandtl number of near unity (such as gases), and negligible pressure gradient in the flow direction (such as flow over a flat plate).

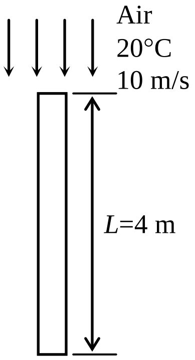
6-48C Modified Reynolds analogy is expressed as $C_{f,x}\dfrac{\text{Re}_L}{2} = \text{Nu}_x\,\text{Pr}^{-1/3}$ or $\dfrac{C_{f,x}}{2} = \dfrac{h_x}{\rho C_p \mathcal{V}}\text{Pr}^{2/3} \equiv j_H$. It allows us to calculate the heat transfer coefficient from a knowledge of friction coefficient. It is valid for a Prandtl number range of 0.6 < Pr < 60. This relation is developed using relations for laminar flow over a flat plate, but it is also applicable approximately for turbulent flow over a surface, even in the presence of pressure gradients.

6-49 A flat plate is subjected to air flow, and the drag force acting on it is measured. The average convection heat transfer coefficient and the rate of heat transfer are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The edge effects are negligible.

Properties The properties of air at 20°C and 1 atm are (Table A-15)

$$\rho = 1.204\ \text{kg/m}^3,\qquad C_p = 1.007\ \text{kJ/kg-K},\qquad \text{Pr} = 0.7309$$



Analysis The flow is along the 4-m side of the plate, and thus the characteristic length is L = 4 m. Both sides of the plate is exposed to air flow, and thus the total surface area is

$$A_s = 2WL = 2(4\ \text{m})(4\ \text{m}) = 32\ \text{m}^2$$

For flat plates, the drag force is equivalent to friction force. The average friction coefficient C_f can be determined from

$$F_f = C_f A_s \frac{\rho V^2}{2} \longrightarrow C_f = \frac{F_f}{\rho A_s V^2/2} = \frac{2.4\ \text{N}}{(1.204\ \text{kg/m}^3)(32\ \text{m}^2)(10\ \text{m/s})^2/2}\left(\frac{1\ \text{kg}\cdot\text{m/s}^2}{1\ \text{N}}\right) = 0.006229$$

Then the average heat transfer coefficient can be determined from the modified Reynolds analogy to be

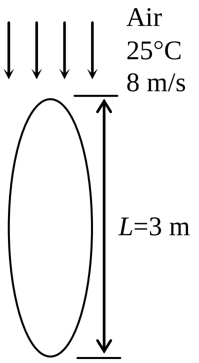
$$h = \frac{C_f}{2}\frac{\rho V C_p}{\text{Pr}^{2/3}} = \frac{0.006229}{2}\frac{(1.204\ \text{kg/m}^3)(10\ \text{m/s})(1007\ \text{J/kg}\cdot{}^\circ\text{C})}{(0.7309)^{2/3}} = \mathbf{46.54\ W/m^2\cdot C}$$

Them the rate of heat transfer becomes

$$\dot{Q} = hA_s(T_s - T_\infty) = (46.54\ \text{W/m}^2\cdot{}^\circ\text{C})(32\ \text{m}^2)(80-20)^\circ\text{C} = \mathbf{89{,}356\ W}$$

6-50 A metallic airfoil is subjected to air flow. The average friction coefficient is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The edge effects are negligible.



Properties The properties of air at 25°C and 1 atm are (Table A-15)

$$\rho = 1.184\ \text{kg/m}^3, \quad C_p = 1.007\ \text{kJ/kg-K}, \quad \Pr = 0.7296$$

Analysis First, we determine the rate of heat transfer from

$$\dot{Q} = \frac{mC_{\text{p,airfoil}}(T_2 - T_1)}{\Delta t} = \frac{(50\ \text{kg})(500\ \text{J/kg}\cdot°\text{C})(160-150)°\text{C}}{(2\times 60\ \text{s})} = 2083\ \text{W}$$

Then the average heat transfer coefficient is

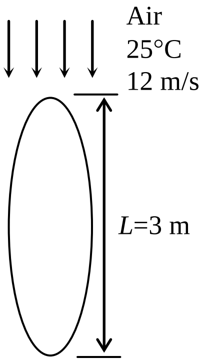
$$\dot{Q} = hA_s(T_s - T_\infty) \longrightarrow h = \frac{\dot{Q}}{A_s(T_s - T_\infty)} = \frac{2083\ \text{W}}{(12\ \text{m}^2)(155-25)°\text{C}} = 1.335\ \text{W/m}^2\cdot°\text{C}$$

where the surface temperature of airfoil is taken as its average temperature, which is (150+160)/2=155°C. The average friction coefficient of the airfoil is determined from the modified Reynolds analogy to be

$$C_f = \frac{2h\Pr^{2/3}}{\rho V C_p} = \frac{2(1.335\ \text{W/m}^2\cdot°\text{C})(0.7296)^{2/3}}{(1.184\ \text{kg/m}^3)(8\ \text{m/s})(1007\ \text{J/kg}\cdot°\text{C})} = \mathbf{0.000227}$$

6-51 A metallic airfoil is subjected to air flow. The average friction coefficient is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The edge effects are negligible.



Properties The properties of air at 25°C and 1 atm are (Table A-15)

$$\rho = 1.184\ \text{kg/m}^3, \quad C_p = 1.007\ \text{kJ/kg-K}, \quad \Pr = 0.7296$$

Analysis First, we determine the rate of heat transfer from

$$\dot{Q} = \frac{mC_{\text{p,airfoil}}(T_2 - T_1)}{\Delta t} = \frac{(50\ \text{kg})(500\ \text{J/kg}\cdot°\text{C})(160-150)°\text{C}}{(2\times 60\ \text{s})} = 2083\ \text{W}$$

Then the average heat transfer coefficient is

$$\dot{Q} = hA_s(T_s - T_\infty) \longrightarrow h = \frac{\dot{Q}}{A_s(T_s - T_\infty)} = \frac{2083\ \text{W}}{(12\ \text{m}^2)(155-25)°\text{C}} = 1.335\ \text{W/m}^2\cdot°\text{C}$$

where the surface temperature of airfoil is taken as its average temperature, which is (150+160)/2=155°C. The average friction coefficient of the airfoil is determined from the modified Reynolds analogy to be

$$C_f = \frac{2h\Pr^{2/3}}{\rho V C_p} = \frac{2(1.335\ \text{W/m}^2\cdot°\text{C})(0.7296)^{2/3}}{(1.184\ \text{kg/m}^3)(12\ \text{m/s})(1007\ \text{J/kg}\cdot°\text{C})} = \mathbf{0.0001512}$$

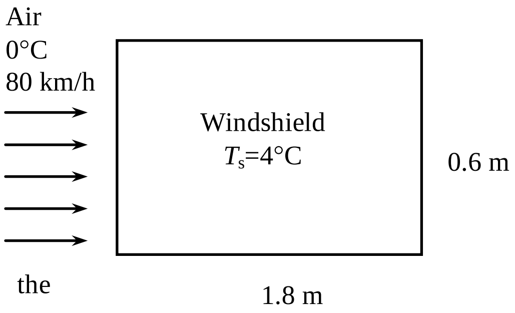
6-52 The windshield of a car is subjected to parallel winds. The drag force the wind exerts on the windshield is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The edge effects are negligible.

Properties The properties of air at 0°C and 1 atm are (Table A-15)

$\rho = 1.292\ \text{kg/m}^3, \quad C_p = 1.006\ \text{kJ/kg-K}, \quad \text{Pr} = 0.7362$

Analysis The average heat transfer coefficient is



$$\dot{Q} = hA_s(T_s - T_\infty)$$

$$h = \frac{\dot{Q}}{A_s(T_s - T_\infty)} = \frac{50\ \text{W}}{(0.6\times1.8\ \text{m}^2)(4-0)°\text{C}} = 11.57\ \text{W/m}^2\cdot°\text{C}$$

The average friction coefficient is determined from the modified Reynolds analogy to be

$$C_f = \frac{2h\text{Pr}^{2/3}}{\rho \text{V} C_p} = \frac{2(11.57\ \text{W/m}^2\cdot°\text{C})(0.7362)^{2/3}}{(1.292\ \text{kg/m}^3)(80/3.6\ \text{m/s})(1006\ \text{J/kg}\cdot°\text{C})} = 0.0006534$$

The drag force is determined from

$$F_f = C_f A_s \frac{\rho \text{V}^2}{2} = 0.0006534(0.6\times1.8\ \text{m}^2)\frac{(1.292\ \text{kg/m}^3)(80/3.6\ \text{m/s})^2}{2}\left(\frac{1\ \text{N}}{1\ \text{kg.m/s}^2}\right) = \mathbf{0.225\ N}$$

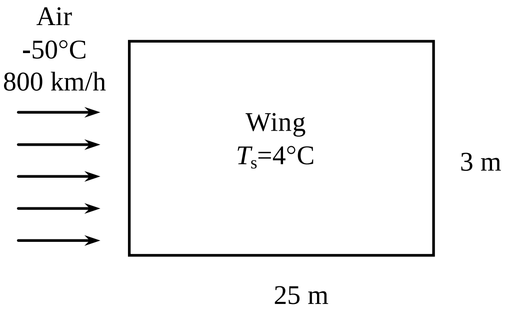
6-53 An airplane cruising is considered. The average heat transfer coefficient is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The edge effects are negligible.

Properties The properties of air at -50°C and 1 atm are (Table A-15)

$C_p = 0.999\ \text{kJ/kg-K} \qquad \text{Pr} = 0.7440$

The density of air at -50°C and 26.5 kPa is



$$\rho = \frac{P}{RT} = \frac{26.5\ \text{kPa}}{(0.287\ \text{kJ/kg.K})(-50+273)\text{K}} = 0.4141\ \text{kg/m}^3$$

Analysis The average heat transfer coefficient can be determined from the modified Reynolds analogy to be

$$h = \frac{C_f}{2}\frac{\rho \text{V} C_p}{\text{Pr}^{2/3}} = \frac{0.0016}{2}\frac{(0.4141\ \text{kg/m}^3)(800/3.6\ \text{m/s})(999\ \text{J/kg}\cdot°\text{C})}{(0.7440)^{2/3}} = \mathbf{89.6\ W/m^2\cdot C}$$

Chapter 7
EXTERNAL FORCED CONVECTION

Drag Force and Heat Transfer in External Flow

7-1C The velocity of the fluid relative to the immersed solid body sufficiently far away from a body is called the *free-stream velocity*, $\mathbf{V}_\infty$. The *upstream* (or *approach*) *velocity* **V** is the velocity of the approaching fluid far ahead of the body. These two velocities are equal if the flow is uniform and the body is small relative to the scale of the free-stream flow.

7-2C A body is said to be *streamlined* if a conscious effort is made to align its shape with the anticipated streamlines in the flow. Otherwise, a body tends to block the flow, and is said to be *blunt*. A tennis ball is a blunt body (unless the velocity is very low and we have “creeping flow”).

7-3C The force a flowing fluid exerts on a body in the flow direction is called *drag*. Drag is caused by friction between the fluid and the solid surface, and the pressure difference between the front and back of the body. We try to minimize drag in order to reduce fuel consumption in vehicles, improve safety and durability of structures subjected to high winds, and to reduce noise and vibration.

7-4C The force a flowing fluid exerts on a body in the normal direction to flow that tend to move the body in that direction is called *lift*. It is caused by the components of the pressure and wall shear forces in the normal direction to flow. The wall shear also contributes to lift (unless the body is very slim), but its contribution is usually small.

7-5C When the drag force F_D, the upstream velocity **V**, and the fluid density ρ are measured during flow over a body, the drag coefficient can be determined from

$$C_D = \frac{F_D}{\frac{1}{2}\rho \mathbf{V}^2 A}$$

where A is ordinarily the *frontal area* (the area projected on a plane normal to the direction of flow) of the body.

7-6C The *frontal area* of a body is the area seen by a person when looking from upstream. The frontal area is appropriate to use in drag and lift calculations for blunt bodies such as cars, cylinders, and spheres.

7-7C The part of drag that is due directly to wall shear stress τ_w is called the *skin friction drag* $F_{D,\text{ friction}}$ since it is caused by frictional effects, and the part that is due directly to pressure P and depends strongly on the shape of the body is called the *pressure drag* $F_{D,\text{ pressure}}$. For slender bodies such as airfoils, the friction drag is usually more significant.

7-8C The friction drag coefficient is independent of surface roughness in *laminar flow*, but is a strong function of surface roughness in *turbulent flow* due to surface roughness elements protruding further into the highly viscous laminar sublayer.

7-9C As a result of streamlining, (*a*) friction drag increases, (*b*) pressure drag decreases, and (*c*) total drag decreases at high Reynolds numbers (the general case), but increases at very low Reynolds numbers since the friction drag dominates at low Reynolds numbers.

7-10C At sufficiently high velocities, the fluid stream detaches itself from the surface of the body. This is called *separation*. It is caused by a fluid flowing over a curved surface at a high velocity (or technically, by adverse pressure gradient). Separation increases the drag coefficient drastically.

Flow over Flat Plates

7-11C The friction coefficient represents the resistance to fluid flow over a flat plate. It is proportional to the drag force acting on the plate. The drag coefficient for a flat surface is equivalent to the mean friction coefficient.

7-12C The friction and the heat transfer coefficients change with position in laminar flow over a flat plate.

7-13C The average friction and heat transfer coefficients in flow over a flat plate are determined by integrating the local friction and heat transfer coefficients over the entire plate, and then dividing them by the length of the plate.

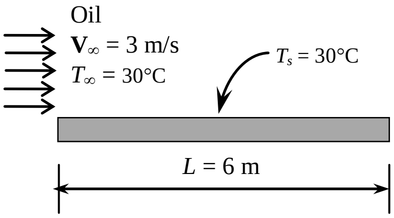
7-14 Hot engine oil flows over a flat plate. The total drag force and the rate of heat transfer per unit width of the plate are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\mathrm{Re}_{cr} = 5\times10^5$. **3** Radiation effects are negligible.

Properties The properties of engine oil at the film temperature of $(T_s + T_\infty)/2 = (80+30)/2 = 55°\mathrm{C} = 328$ K are (Table A-13)

$$\rho = 867\ \mathrm{kg/m^3} \qquad \upsilon = 123\times10^{-6}\ \mathrm{m^2/s}$$
$$k = 0.141\ \mathrm{W/m.°C} \qquad \mathrm{Pr} = 1505$$

Analysis Noting that L = 6 m, the Reynolds number at the end of the plate is



$$\mathrm{Re}_L = \frac{\mathbf{V}_\infty L}{\upsilon} = \frac{(3\ \mathrm{m/s})(6\ \mathrm{m})}{123\times10^{-6}\ \mathrm{m^2/s}} = 1.46\times10^5$$

which is less than the critical Reynolds number. Thus we have laminar flow over the entire plate. The average friction coefficient and the drag force per unit width are determined from

$$C_f = 1.328\,\mathrm{Re}_L^{-0.5} = 1.328(1.46\times10^5)^{-0.5} = 0.00347$$

$$F_D = C_f A_s \frac{\rho \mathbf{V}_\infty^2}{2} = (0.00347)(6\times1\,\mathrm{m^2})\frac{(867\ \mathrm{kg/m^3})(3\,\mathrm{m/s})^2}{2} = 81.3\,\mathrm{N}$$

Similarly, the average Nusselt number and the heat transfer coefficient are determined using the laminar flow relations for a flat plate,

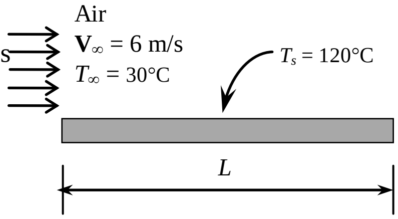
$$Nu = \frac{hL}{k} = 0.664\,\mathrm{Re}_L^{0.5}\,\mathrm{Pr}^{1/3} = 0.664(1.46\times10^5)^{0.5}(1505)^{1/3} = 2908$$

$$h = \frac{k}{L}Nu = \frac{0.141\ \mathrm{W/m.°C}}{6\ \mathrm{m}}(2908) = 68.3\ \mathrm{W/m^2.°C}$$

The rate of heat transfer is then determined from Newton's law of cooling to be

$$\dot{Q} = hA_s(T_\infty - T_s) = (68.3\,\mathrm{W/m^2.°C})(6\times1\,\mathrm{m^2})(80-30)°\mathrm{C} = 2.05\times10^4\ \mathrm{W} = \mathbf{20.5\,kW}$$

7-15 The top surface of a hot block is to be cooled by forced air. The rate of heat transfer is to be determined for two cases.



Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\text{Re}_{cr} = 5\times10^5$. **3** Radiation effects are negligible. **4** Air is an ideal gas with constant properties.

Properties The atmospheric pressure in atm is

$$P = (83.4\,\text{kPa})\frac{1\,\text{atm}}{101.325\,\text{kPa}} = 0.823\,\text{atm}$$

For an ideal gas, the thermal conductivity and the Prandtl number are independent of pressure, but the kinematic viscosity is inversely proportional to the pressure. With these considerations, the properties of air at 0.823 atm and at the film temperature of (120+30)/2=75°C are (Table A-15)

$$k = 0.02917\text{ W/m.°C}$$

$$\upsilon = \upsilon_{@1atm} / P_{atm} = (2.046\times10^{-5}\text{ m}^2/\text{s}) / 0.823 = 2.486\times10^{-5}\text{ m}^2/\text{s}$$

$$\text{Pr} = 0.7166$$

Analysis (*a*) If the air flows parallel to the 8 m side, the Reynolds number in this case becomes

$$\text{Re}_L = \frac{\mathbf{V}_\infty L}{\upsilon} = \frac{(6\text{ m/s})(8\text{ m})}{2.486\times10^{-5}\text{ m}^2/\text{s}} = 1.931\times10^6$$

which is greater than the critical Reynolds number. Thus we have combined laminar and turbulent flow. Using the proper relation for Nusselt number, the average heat transfer coefficient and the heat transfer rate are determined to be

$$Nu = \frac{hL}{k} = (0.037\,\text{Re}_L{}^{0.8} - 871)\,\text{Pr}^{1/3} = [0.037(1.931\times10^6)^{0.8} - 871](0.7166)^{1/3} = 2757$$

$$h = \frac{k}{L}Nu = \frac{0.02917\text{ W/m.°C}}{8\text{ m}}(2757) = 10.05\text{ W/m}^2\text{.°C}$$

$$A_s = wL = (2.5\text{ m})(8\text{ m}) = 20\text{ m}^2$$

$$\dot{Q} = hA_s(T_\infty - T_s) = (10.05\text{ W/m}^2\text{.°C})(20\text{ m}^2)(120\text{ - }30)\text{°C} = 18{,}096\text{ W} = \mathbf{18.10\ kW}$$

(*b*) If the air flows parallel to the 2.5 m side, the Reynolds number is

$$\text{Re}_L = \frac{\mathbf{V}_\infty L}{\upsilon} = \frac{(6\text{ m/s})(2.5\text{ m})}{2.486\times10^{-5}\text{ m}^2/\text{s}} = 6.034\times10^5$$

which is greater than the critical Reynolds number. Thus we have combined laminar and turbulent flow. Using the proper relation for Nusselt number, the average heat transfer coefficient and the heat transfer rate are determined to be

$$Nu = \frac{hL}{k} = (0.037\,\text{Re}_L{}^{0.8} - 871)\,\text{Pr}^{1/3} = [0.037(6.034\times10^5)^{0.8} - 871](0.7166)^{1/3} = 615.1$$

$$h = \frac{k}{L}Nu = \frac{0.029717\text{ W/m.°C}}{2.5\text{ m}}(615.1) = 7.177\text{ W/m}^2\text{.°C}$$

$$A_s = wL = (8\text{ m})(2.5\text{ m}) = 20\text{ m}^2$$

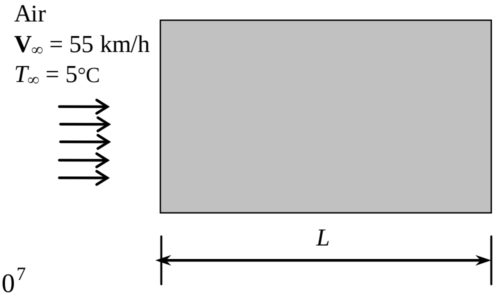
$$\dot{Q} = hA_s(T_\infty - T_s) = (7.177\text{ W/m}^2\text{.°C})(20\text{ m}^2)(120\text{ - }30)\text{°C} = 12{,}919\text{ W} = \mathbf{12.92\ kW}$$

7-16 Wind is blowing parallel to the wall of a house. The rate of heat loss from that wall is to be determined for two cases.

Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\mathrm{Re}_{cr} = 5\times10^5$. **3** Radiation effects are negligible. **4** Air is an ideal gas with constant properties.

Properties The properties of air at 1 atm and the film temperature of $(T_s + T_\infty)/2 = (12+5)/2 = 8.5$°C are (Table A-15)

$$k = 0.02428 \text{ W/m.°C}$$
$$\upsilon = 1.413\times10^{-5} \text{ m}^2\text{/s}$$
$$\Pr = 0.7340$$



Analysis *Air flows parallel to the 10 m side*:

The Reynolds number in this case is

$$\mathrm{Re}_L = \frac{\mathbf{V}_\infty L}{\upsilon} = \frac{[(55\times1000/3600)\text{m/s}](10\text{ m})}{1.413\times10^{-5}\text{ m}^2\text{/s}} = 1.081\times10^7$$

which is greater than the critical Reynolds number. Thus we have combined laminar and turbulent flow. Using the proper relation for Nusselt number, heat transfer coefficient and then heat transfer rate are determined to be

$$Nu = \frac{hL}{k} = (0.037\,\mathrm{Re}_L^{\;0.8} - 871)\Pr^{1/3} = [0.037(1.081\times10^7)^{0.8} - 871](0.7340)^{1/3} = 1.336\times10^4$$

$$h = \frac{k}{L}Nu = \frac{0.02428\text{ W/m.°C}}{10\text{ m}}(1.336\times10^4) = 32.43\text{ W/m}^2\text{.°C}$$

$$A_s = wL = (4\text{ m})(10\text{ m}) = 40\text{ m}^2$$

$$\dot{Q} = hA_s(T_\infty - T_s) = (32.43\text{ W/m}^2\text{.°C})(40\text{ m}^2)(12\text{ - }5)\text{°C} = 9081\text{ W} = \mathbf{9.08\,kW}$$

If the wind velocity is doubled:

$$\mathrm{Re}_L = \frac{\mathbf{V}_\infty L}{\upsilon} = \frac{[(110\times1000/3600)\text{m/s}](10\text{ m})}{1.413\times10^{-5}\text{ m}^2\text{/s}} = 2.163\times10^7$$

which is greater than the critical Reynolds number. Thus we have combined laminar and turbulent flow. Using the proper relation for Nusselt number, the average heat transfer coefficient and the heat transfer rate are determined to be

$$Nu = \frac{hL}{k} = (0.037\,\mathrm{Re}_L^{\;0.8} - 871)\Pr^{1/3} = [0.037(2.163\times10^7)^{0.8} - 871](0.7340)^{1/3} = 2.384\times10^4$$

$$h = \frac{k}{L}Nu = \frac{0.02428\text{ W/m.°C}}{10\text{ m}}(2.384\times10^4) = 57.88\text{ W/m}^2\text{.°C}$$

$$A_s = wL = (10\text{ m})(4\text{ m}) = 40\text{ m}^2$$

$$\dot{Q} = hA_s(T_\infty - T_s) = (57.88\text{ W/m}^2\text{.°C})(40\text{ m}^2)(12\text{ - }5)\text{°C} = 16{,}206\text{ W} = \mathbf{16.21\,kW}$$

7-18E Air flows over a flat plate. The local friction and heat transfer coefficients at intervals of 1 ft are to be determined and plotted against the distance from the leading edge.

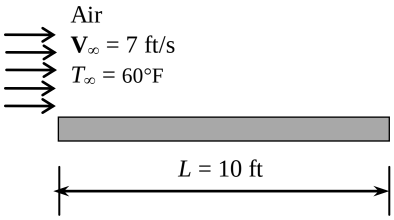
Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\mathrm{Re}_{cr} = 5\times10^5$. **3** Radiation effects are negligible. **4** Air is an ideal gas with constant properties.

Properties The properties of air at 1 atm and 60°F are (Table A-15E)

$$k = 0.01433\ \text{Btu/h.ft.°F}$$

$$\upsilon = 0.1588\times10^{-3}\ \text{ft}^2/\text{s}$$

$$\mathrm{Pr} = 0.7321$$



Analysis For the first 1 ft interval, the Reynolds number is

$$\mathrm{Re}_L = \frac{\mathbf{V}_\infty L}{\upsilon} = \frac{(7\ \text{ft/s})(1\ \text{ft})}{0.1588\times10^{-3}\ \text{ft}^2/\text{s}} = 4.407\times10^4$$

which is less than the critical value of 5×10^5. Therefore, the flow is laminar. The local Nusselt number is

$$Nu_x = \frac{hx}{k} = 0.332\,\mathrm{Re}_x^{\ 0.5}\,\mathrm{Pr}^{1/3} = 0.332(4.407\times10^4)^{0.5}(0.7321)^{1/3} = 62.82$$

The local heat transfer and friction coefficients are

$$h_x = \frac{k}{x}Nu = \frac{0.01433\ \text{Btu/h.ft.°F}}{1\ \text{ft}}(62.82) = 0.9002\ \text{Btu/h.ft}^2.\text{°F}$$

$$C_{f,x} = \frac{0.664}{\mathrm{Re}^{0.5}} = \frac{0.664}{(4.407\times10^4)^{0.5}} = 0.00316$$

We repeat calculations for all 1-ft intervals. The results are

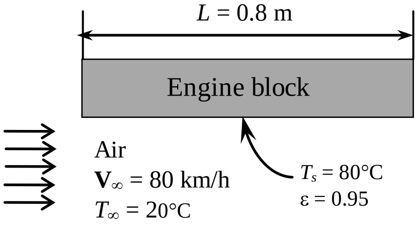
7-20 A car travels at a velocity of 80 km/h. The rate of heat transfer from the bottom surface of the hot automotive engine block is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\text{Re}_{cr} = 5\times10^5$. **3** Air is an ideal gas with constant properties. **4** The flow is turbulent over the entire surface because of the constant agitation of the engine block.



Properties The properties of air at 1 atm and the film temperature of $(T_s + T_\infty)/2 = (80+20)/2 = 50°C$ are (Table A-15)

$$k = 0.02735 \text{ W/m.°C}$$
$$\upsilon = 1.798\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7228$$

Analysis Air flows parallel to the 0.4 m side. The Reynolds number in this case is

$$\text{Re}_L = \frac{\mathbf{V}_\infty L}{\upsilon} = \frac{[(80\times1000/3600)\text{ m/s}](0.8\text{ m})}{1.798\times10^{-5}\text{ m}^2\text{/s}} = 9.888\times10^5$$

which is less than the critical Reynolds number. But the flow is assumed to be turbulent over the entire surface because of the constant agitation of the engine block. Using the proper relations, the Nusselt number, the heat transfer coefficient, and the heat transfer rate are determined to be

$$Nu = \frac{hL}{k} = 0.037\,\text{Re}_L^{0.8}\,\text{Pr}^{1/3} = 0.037(9.888\times10^5)^{0.8}(0.7228)^{1/3} = 2076$$
$$h = \frac{k}{L}Nu = \frac{0.02735\text{ W/m.°C}}{0.8\text{ m}}(2076) = 70.98\text{ W/m}^2\text{.°C}$$
$$A_s = wL = (0.8\text{ m})(0.4\text{ m}) = 0.32\text{ m}^2$$
$$\dot{Q}_{conv} = hA_s(T_\infty - T_s) = (70.98\text{ W/m}^2\text{.°C})(0.32\text{ m}^2)(80-20)\text{°C} = \mathbf{1363\ W}$$

The radiation heat transfer from the same surface is

$$\dot{Q}_{rad} = \varepsilon A_s\sigma(T_s^4 - T_{surr}^4) = (0.95)(0.32\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\text{.K}^4)[(80+273\text{ K})^4 - (25+273\text{ K})^4]$$
$$= \mathbf{132\ W}$$

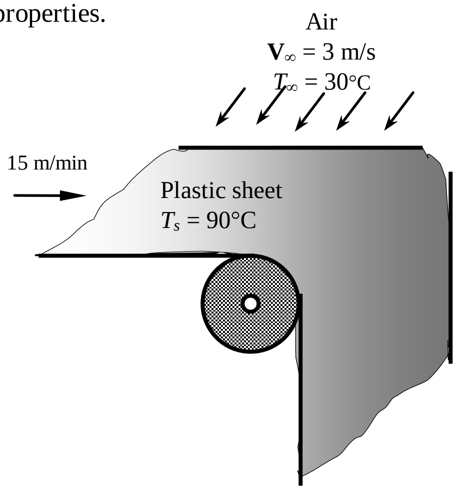
Then the total rate of heat transfer from that surface becomes

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad} = (1363+132)\text{W} = \mathbf{1495\ W}$$

7-21 Air flows on both sides of a continuous sheet of plastic. The rate of heat transfer from the plastic sheet is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\text{Re}_{cr} = 5\times10^5$. **3** Radiation effects are negligible. **4** Air is an ideal gas with constant properties.

Properties The properties of air at 1 atm and the film temperature of $(T_s + T_\infty)/2 = (90+30)/2 = 60°\text{C}$ are (Table A-15)



$$\rho = 1.059 \text{ kg/m}^3$$
$$k = 0.02808 \text{ W/m.°C}$$
$$\upsilon = 1.896\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7202$$

Analysis The width of the cooling section is first determined from

$$W = \mathbf{V}\Delta t = [(15/60)\text{ m/s}](2\text{ s}) = 0.5\text{ m}$$

The Reynolds number is

$$\text{Re}_L = \frac{\mathbf{V}_\infty L}{\upsilon} = \frac{(3\text{ m/s})(1.2\text{ m})}{1.896\times10^{-5}\text{ m}^2\text{/s}} = 1.899\times10^5$$

which is less than the critical Reynolds number. Thus the flow is laminar. Using the proper relation in laminar flow for Nusselt number, the average heat transfer coefficient and the heat transfer rate are determined to be

$$Nu = \frac{hL}{k} = 0.664\,\text{Re}_L^{\,0.5}\,\text{Pr}^{1/3} = 0.664(1.899\times10^5)^{0.5}(0.7202)^{1/3} = 259.7$$

$$h = \frac{k}{L}Nu = \frac{0.0282\text{ W/m.°C}}{1.2\text{ m}}(259.7) = 6.07\text{ W/m}^2\text{.°C}$$

$$A_s = 2LW = 2(1.2\text{ m})(0.5\text{ m}) = 1.2\text{ m}^2$$

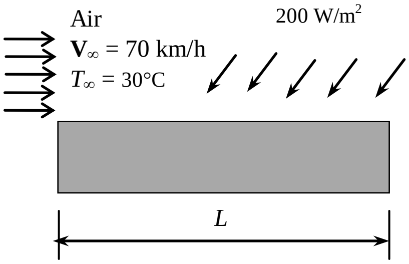
$$\dot{Q}_{conv} = hA_s(T_\infty - T_s) = (6.07\text{ W/m}^2\text{.°C})(1.2\text{ m}^2)(90-30)\text{°C} = \mathbf{437\text{ W}}$$

7-22 The top surface of the passenger car of a train in motion is absorbing solar radiation. The equilibrium temperature of the top surface is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\mathrm{Re}_{cr} = 5\times10^5$. **3** Radiation heat exchange with the surroundings is negligible. **4** Air is an ideal gas with constant properties.

Properties The properties of air at 30°C are (Table A-15)

$$k = 0.02588 \text{ W/m.°C}$$
$$\upsilon = 1.608\times10^{-5} \text{ m}^2\text{/s}$$
$$\mathrm{Pr} = 0.7282$$



Analysis The rate of convection heat transfer from the top surface of the car to the air must be equal to the solar radiation absorbed by the same surface in order to reach steady operation conditions. The Reynolds number is

$$\mathrm{Re}_L = \frac{\mathbf{V}_\infty L}{\upsilon} = \frac{[70\times1000/3600)\text{ m/s}](8\text{ m})}{1.608\times10^{-5}\text{ m}^2\text{/s}} = 9.674\times10^6$$

which is greater than the critical Reynolds number. Thus we have combined laminar and turbulent flow. Using the proper relation for Nusselt number, the average heat transfer coefficient and the heat transfer rate are determined to be

$$Nu = \frac{hL}{k} = (0.037\,\mathrm{Re}_L^{\,0.8} - 871)\,\mathrm{Pr}^{1/3} = [0.037(9.674\times10^6)^{0.8} - 871](0.7282)^{1/3} = 1.212\times10^4$$

$$h = \frac{k}{L}Nu = \frac{0.02588\text{ W/m.°C}}{8\text{ m}}(1.212\times10^4) = 39.21\text{ W/m}^2\text{.°C}$$

The equilibrium temperature of the top surface is then determined by taking convection and radiation heat fluxes to be equal to each other

$$\dot{q}_{rad} = \dot{q}_{conv} = h(T_s - T_\infty) \longrightarrow T_s = T_\infty + \frac{\dot{q}_{conv}}{h} = 30\text{°C} + \frac{200\text{ W/m}^2}{39.21\text{ W/m}^2\text{.°C}} = \mathbf{35.1°C}$$

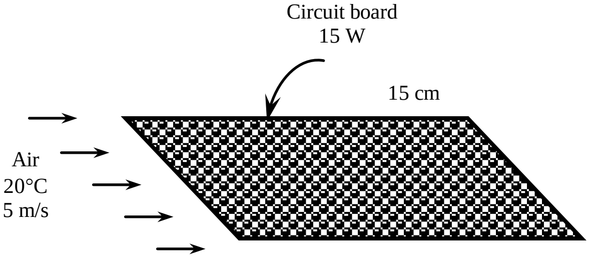
7-24 A circuit board is cooled by air. The surface temperatures of the electronic components at the leading edge and the end of the board are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\text{Re}_{cr} = 5\times10^5$. **3** Radiation effects are negligible. **4** Any heat transfer from the back surface of the board is disregarded. **5** Air is an ideal gas with constant properties.

Properties Assuming the film temperature to be approximately 35°C, the properties of air are evaluated at this temperature to be (Table A-15)

$$k = 0.0265\ \text{W/m.°C}$$
$$\upsilon = 1.655\times10^{-5}\ \text{m}^2\text{/s}$$
$$\text{Pr} = 0.7268$$



Analysis (*a*) The convection heat transfer coefficient at the leading edge approaches infinity, and thus the surface temperature there must approach the air temperature, which is 20°C.

(*b*) The Reynolds number is

$$\text{Re}_x = \frac{\mathbf{V}_\infty x}{\upsilon} = \frac{(5\ \text{m/s})(0.15\ \text{m})}{1.655\times10^{-5}\ \text{m}^2\text{/s}} = 4.532\times10^4$$

which is less than the critical Reynolds number but we assume the flow to be turbulent since the electronic components are expected to act as turbulators. Using the Nusselt number uniform heat flux, the local heat transfer coefficient at the end of the board is determined to be

$$Nu_x = \frac{h_x x}{k} = 0.0308\,\text{Re}_x^{\,0.8}\,\text{Pr}^{1/3} = 0.0308(4.532\times10^4)^{0.8}(0.7268)^{1/3} = 147.0$$

$$h_x = \frac{k_x}{x} Nu_x = \frac{0.02625\ \text{W/m.°C}}{0.15\ \text{m}}(147.0) = 25.73\ \text{W/m}^2\text{.°C}$$

Then the surface temperature at the end of the board becomes

$$\dot{q} = h_x(T_s - T_\infty) \longrightarrow T_s = T_\infty + \frac{\dot{q}}{h_x} = 20\text{°C} + \frac{(15\ \text{W})/(0.15\ \text{m})^2}{25.73\ \text{W/m}^2\text{.°C}} = \mathbf{45.9°C}$$

Discussion The heat flux can also be determined approximately using the relation for isothermal surfaces,

$$Nu_x = \frac{h_x x}{k} = 0.0296\,\text{Re}_x^{\,0.8}\,\text{Pr}^{1/3} = 0.0296(45{,}320)^{0.8}(0.7268)^{1/3} = 141.3$$

$$h_x = \frac{k_x}{x} Nu_x = \frac{0.02625\ \text{W/m.°C}}{0.15\ \text{m}}(141.3) = 24.73\ \text{W/m}^2\text{.°C}$$

Then the surface temperature at the end of the board becomes

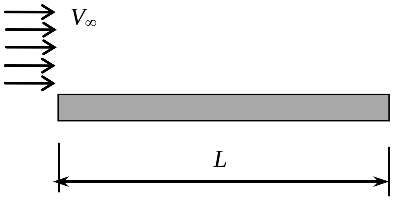
$$\dot{q} = h_x(T_s - T_\infty) \longrightarrow T_s = T_\infty + \frac{\dot{q}}{h_x} = 20\text{°C} + \frac{(15\ \text{W})/(0.15\ \text{m})^2}{24.73\ \text{W/m}^2\text{.°C}} = \mathbf{47.0°C}$$

Note that the two results are close to each other.

7-25 Laminar flow of a fluid over a flat plate is considered. The change in the drag force and the rate of heat transfer are to be determined when the free-stream velocity of the fluid is doubled.

Analysis For the laminar flow of a fluid over a flat plate maintained at a constant temperature the drag force is given by

$$F_{D1} = C_f A_s \frac{\rho \mathbf{V}_\infty{}^2}{2} \quad \text{where} \quad C_f = \frac{1.328}{\text{Re}^{0.5}}$$



Therefore

$$F_{D1} = \frac{1.328}{\text{Re}^{0.5}} A_s \frac{\rho \mathbf{V}_\infty{}^2}{2}$$

Substituting Reynolds number relation, we get

$$F_{D1} = \frac{1.328}{\left(\dfrac{\mathbf{V}_\infty L}{\upsilon}\right)^{0.5}} A_s \frac{\rho \mathbf{V}_\infty{}^2}{2} = 0.664 \mathbf{V}_\infty{}^{3/2} A_s \frac{\upsilon^{0.5}}{L^{0.5}}$$

When the free-stream velocity of the fluid is doubled, the new value of the drag force on the plate becomes

$$F_{D2} = \frac{1.328}{\left(\dfrac{(2\mathbf{V}_\infty)L}{\upsilon}\right)^{0.5}} A_s \frac{\rho (2\mathbf{V}_\infty)^2}{2} = 0.664 (2\mathbf{V}_\infty)^{3/2} A_s \frac{\upsilon^{0.5}}{L^{0.5}}$$

The ratio of drag forces corresponding to $\mathbf{V}_\infty$ and $2\mathbf{V}_\infty$ is

$$\frac{F_{D2}}{F_{D2}} = \frac{(2V_\infty)^{3/2}}{V_\infty{}^{3/2}} = \mathbf{2^{3/2}}$$

We repeat similar calculations for heat transfer rate ratio corresponding to $\mathbf{V}_\infty$ and $2\mathbf{V}_\infty$

$$\dot{Q}_1 = hA_s(T_s - T_\infty) = \left(\frac{k}{L} Nu\right) A_s (T_s - T_\infty) = \left(\frac{k}{L}\right)\left(0.664\,\text{Re}^{0.5}\,\text{Pr}^{1/3}\right) A_s (T_s - T_\infty)$$

$$= \frac{k}{L} 0.664 \left(\frac{\mathbf{V}_\infty L}{\upsilon}\right)^{0.5} \text{Pr}^{1/3} A_s (T_s - T_\infty)$$

$$= 0.664 \mathbf{V}_\infty{}^{0.5} \frac{k}{L^{0.5}\upsilon^{0.5}} \text{Pr}^{1/3} A_s (T_s - T_\infty)$$

When the free-stream velocity of the fluid is doubled, the new value of the heat transfer rate between the fluid and the plate becomes

$$\dot{Q}_2 = 0.664 (2\mathbf{V}_\infty)^{0.5} \frac{k}{L^{0.5}\upsilon^{0.5}} \text{Pr}^{1/3} A_s (T_s - T_\infty)$$

Then the ratio is

$$\frac{\dot{Q}_2}{\dot{Q}_1} = \frac{(2\mathbf{V}_\infty)^{0.5}}{\mathbf{V}_\infty{}^{0.5}} = 2^{0.5} = \mathbf{\sqrt{2}}$$

7-26E A refrigeration truck is traveling at 55 mph. The average temperature of the outer surface of the refrigeration compartment of the truck is to be determined.

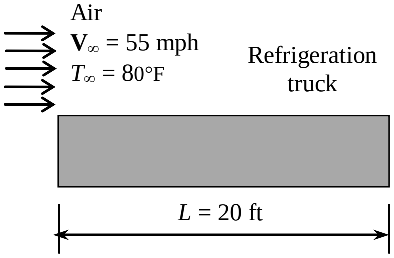
Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\text{Re}_{cr} = 5\times10^5$. **3** Radiation effects are negligible. **4** Air is an ideal gas with constant properties. **5** The local atmospheric pressure is 1 atm.

Properties Assuming the film temperature to be approximately 80°F, the properties of air at this temperature and 1 atm are (Table A-15E)

$$k = 0.01481\ \text{Btu/h.ft.°F}$$

$$\upsilon = 0.1697\times10^{-3}\ \text{ft}^2/\text{s}$$

$$\text{Pr} = 0.7290$$



Analysis The Reynolds number is

$$\text{Re}_L = \frac{\mathbf{V}_\infty L}{\upsilon} = \frac{[55\times5280/3600)\ \text{ft/s}](20\ \text{ft})}{0.1697\times10^{-3}\ \text{ft}^2/\text{s}} = 9.506\times10^6$$

We assume the air flow over the entire outer surface to be turbulent. Therefore using the proper relation in turbulent flow for Nusselt number, the average heat transfer coefficient is determined to be

$$Nu = \frac{hL}{k} = 0.037\,\text{Re}_L^{\,0.8}\,\text{Pr}^{1/3} = 0.037(9.506\times10^6)^{0.8}(0.7290)^{1/3} = 1.273\times10^4$$

$$h = \frac{k}{L}Nu = \frac{0.01481\ \text{Btu/h.ft.°F}}{20\ \text{ft}}(1.273\times10^4) = 9.427\ \text{Btu/h.ft}^2.\text{°F}$$

Since the refrigeration system is operated at half the capacity, we will take half of the heat removal rate

$$\dot{Q} = \frac{(600\times60)\ \text{Btu/h}}{2} = 18{,}000\ \text{Btu/h}$$

The total heat transfer surface area and the average surface temperature of the refrigeration compartment of the truck are determined from

$$A = 2\big[(20\ \text{ft})(9\ \text{ft}) + (20\ \text{ft})(8\ \text{ft}) + (9\ \text{ft})(8\ \text{ft})\big] = 824\ \text{ft}^2$$

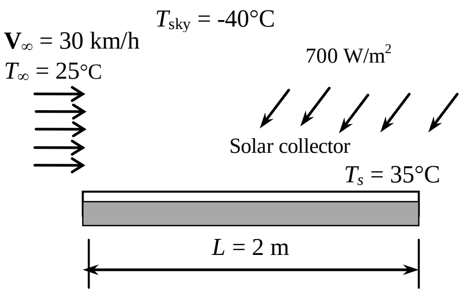
$$\dot{Q} = hA_s(T_\infty - T_s) \longrightarrow T_s = T_\infty - \frac{\dot{Q}_{conv}}{hA_s} = 80\text{°F} - \frac{18{,}000\ \text{Btu/h}}{(9.427\ \text{Btu/h.ft}^2.\text{°F})(824\ \text{ft}^2)} = \mathbf{77.7°F}$$

7-27 Solar radiation is incident on the glass cover of a solar collector. The total rate of heat loss from the collector, the collector efficiency, and the temperature rise of water as it flows through the collector are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\mathrm{Re}_{cr} = 5\times10^5$. **3** Heat exchange on the back surface of the absorber plate is negligible. **4** Air is an ideal gas with constant properties. **5** The local atmospheric pressure is 1 atm.

Properties The properties of air at the film temperature of $(35+25)/2 = 30\,°\mathrm{C}$ are (Table A-15)

$$k = 0.02588\ \mathrm{W/m.°C}$$
$$\upsilon = 1.608\times10^{-5}\ \mathrm{m^2/s}$$
$$\mathrm{Pr} = 0.7282$$



Analysis (*a*) Assuming wind flows across 2 m surface, the Reynolds number is determined from

$$\mathrm{Re}_L = \frac{\mathbf{V}_\infty L}{\upsilon} = \frac{(30\times1000/3600)\mathrm{m/s}(2\ \mathrm{m})}{1.608\times10^{-5}\ \mathrm{m^2/s}} = 1.036\times10^6$$

which is greater than the critical Reynolds number (5×10^5). Using the Nusselt number relation for combined laminar and turbulent flow, the average heat transfer coefficient is determined to be

$$Nu = \frac{hL}{k} = (0.037\,\mathrm{Re}^{0.8} - 871)\,\mathrm{Pr}^{1/3} = [0.037(1.036\times10^6)^{0.8} - 871](0.7282)^{1/3} = 1378$$
$$h = \frac{k}{L}Nu = \frac{0.02588\ \mathrm{W/m.°C}}{2\ \mathrm{m}}(1378) = 17.83\ \mathrm{W/m^2.°C}$$

Then the rate of heat loss from the collector by convection is

$$\dot{Q}_{conv} = hA_s(T_\infty - T_s) = (17.83\ \mathrm{W/m^2.°C})(2\times1.2\ \mathrm{m^2})(35\text{-}25)°\mathrm{C} = 427.9\ \mathrm{W}$$

The rate of heat loss from the collector by radiation is

$$\begin{aligned}\dot{Q}_{rad} &= \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)\\ &= (0.90)(2\times1.2\ \mathrm{m^2})(5.67\times10^{-8}\ \mathrm{W/m^2.°C})\left[(35+273\ \mathrm{K})^4 - (-40+273\ \mathrm{K})^4\right]\\ &= 741.2\ \mathrm{W}\end{aligned}$$

and

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad} = 427.9 + 741.2 = \mathbf{1169\ W}$$

(*b*) The net rate of heat transferred to the water is

$$\begin{aligned}\dot{Q}_{net} &= \dot{Q}_{in} - \dot{Q}_{out} = \alpha AI - \dot{Q}_{out}\\ &= (0.88)(2\times1.2\ \mathrm{m^2})(700\ \mathrm{W/m^2}) - 1169\ \mathrm{W}\\ &= 1478 - 1169 = 309\ \mathrm{W}\end{aligned}$$

$$\eta_{collector} = \frac{\dot{Q}_{net}}{\dot{Q}_{in}} = \frac{309\ \mathrm{W}}{1478\ \mathrm{W}} = \mathbf{0.209}$$

(*c*) The temperature rise of water as it flows through the collector is

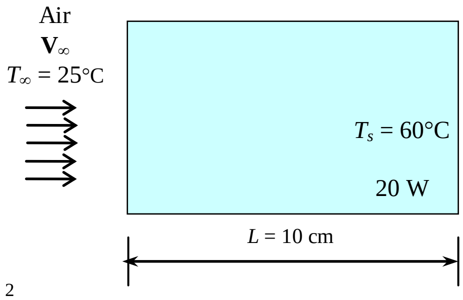
$$\dot{Q}_{net} = \dot{m}C_p\Delta T \longrightarrow \Delta T = \frac{\dot{Q}_{net}}{\dot{m}C_p} = \frac{309.4\ \mathrm{W}}{(1/60\ \mathrm{kg/s})(4180\ \mathrm{J/kg.°C})} = \mathbf{4.44\ °C}$$

7-28 A fan blows air parallel to the passages between the fins of a heat sink attached to a transformer. The minimum free-stream velocity that the fan should provide to avoid overheating is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\text{Re}_{cr} = 5\times10^5$. **3** Radiation effects are negligible. **4** The fins and the base plate are nearly isothermal (fin efficiency is equal to 1) **5** Air is an ideal gas with constant properties. **6** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the film temperature of $(T_s + T_\infty)/2 = (60+25)/2 = 42.5$°C are (Table A-15)

$$k = 0.02681\ \text{W/m.°C}$$
$$\upsilon = 1.726\times10^{-5}\ \text{m}^2/\text{s}$$
$$\text{Pr} = 0.7248$$



Analysis The total heat transfer surface area for this finned surface is

$$A_{\text{s,finned}} = (2\times7)(0.1\ \text{m})(0.005\ \text{m}) = 0.007\ \text{m}^2$$
$$A_{\text{s,unfinned}} = (0.1\ \text{m})(0.062\ \text{m}) - 7\times(0.002\ \text{m})(0.1\ \text{m}) = 0.0048\ \text{m}^2$$
$$A_{\text{s,total}} = A_{\text{s,finned}} + A_{\text{s,unfinned}} = 0.007\ \text{m}^2 + 0.0048\ \text{m}^2 = 0.0118\ \text{m}^2$$

The convection heat transfer coefficient can be determined from Newton's law of cooling relation for a finned surface.

$$\dot{Q} = \eta h A_s(T_\infty - T_s) \longrightarrow h = \frac{\dot{Q}}{\eta A_s(T_\infty - T_s)} = \frac{20\ \text{W}}{(1)(0.0118\ \text{m}^2)(60 - 25)\text{°C}} = 48.43\ \text{W/m}^2.\text{°C}$$

Starting from heat transfer coefficient, Nusselt number, Reynolds number and finally free-stream velocity will be determined. We assume the flow is laminar over the entire finned surface of the transformer.

$$Nu = \frac{hL}{k} = \frac{(48.43\ \text{W/m}^2.\text{°C})(0.1\ \text{m})}{0.02681\ \text{W/m.°C}} = 180.6$$

$$Nu = 0.664\,\text{Re}_L^{0.5}\,\text{Pr}^{1/3} \longrightarrow \text{Re}_L = \frac{Nu^2}{0.664^2\,\text{Pr}^{2/3}} = \frac{(180.6)^2}{(0.664)^2(0.7248)^{2/3}} = 9.171\times10^4$$

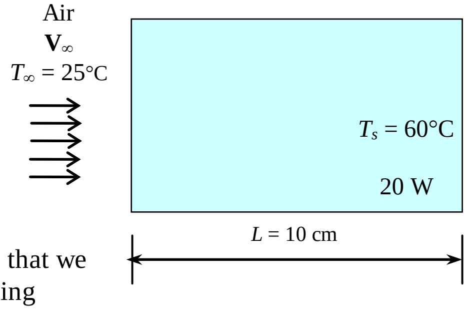
$$\text{Re}_L = \frac{\mathbf{V}_\infty L}{\upsilon} \longrightarrow \mathbf{V}_\infty = \frac{\text{Re}_L\,\upsilon}{L} = \frac{(9.171\times10^4)(1.726\times10^{-5}\ \text{m}^2/\text{s})}{0.1\ \text{m}} = \mathbf{15.83\ m/s}$$

7-29 A fan blows air parallel to the passages between the fins of a heat sink attached to a transformer. The minimum free-stream velocity that the fan should provide to avoid overheating is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\mathrm{Re}_{cr} = 5\times10^5$. **3** The fins and the base plate are nearly isothermal (fin efficiency is equal to 1) **4** Air is an ideal gas with constant properties. **5** The local atmospheric pressure is 1 atm.

Properties The properties of air at the film temperature of $(T_s + T_\infty)/2 = (60+25)/2 = 42.5°\mathrm{C}$ are (Table A-15)

$$k = 0.02681\ \mathrm{W/m.°C}$$
$$\upsilon = 1.726\times10^{-5}\ \mathrm{m^2/s}$$
$$\mathrm{Pr} = 0.7248$$



Analysis We first need to determine radiation heat transfer rate. Note that we will use the base area and we assume the temperature of the surrounding surfaces are at the same temperature with the air ($T_{surr} = 25\ °\mathrm{C}$)

$$\begin{aligned}\dot{Q}_{rad} &= \varepsilon A_s \sigma (T_s{}^4 - T_{surr}{}^4)\\ &= (0.90)[(0.1\,\mathrm{m})(0.062\,\mathrm{m})](5.67\times10^{-8}\ \mathrm{W/m^2.°C})[(60+273\,\mathrm{K})^4 - (25+273\,\mathrm{K})^4]\\ &= 1.4\ \mathrm{W}\end{aligned}$$

The heat transfer rate by convection will be 1.4 W less than total rate of heat transfer from the transformer. Therefore

$$\dot{Q}_{\mathrm{conv}} = \dot{Q}_{\mathrm{total}} - \dot{Q}_{\mathrm{rad}} = 20 - 1.4 = 18.6\ \mathrm{W}$$

The total heat transfer surface area for this finned surface is

$$A_{\mathrm{s,finned}} = (2\times7)(0.1\,\mathrm{m})(0.005\,\mathrm{m}) = 0.007\ \mathrm{m}^2$$
$$A_{\mathrm{s,unfinned}} = (0.1\,\mathrm{m})(0.062\,\mathrm{m}) - 7\times(0.002\,\mathrm{m})(0.1\,\mathrm{m}) = 0.0048\ \mathrm{m}^2$$
$$A_{\mathrm{s,total}} = A_{\mathrm{s,finned}} + A_{\mathrm{s,unfinned}} = 0.007\ \mathrm{m}^2 + 0.0048\ \mathrm{m}^2 = 0.0118\ \mathrm{m}^2$$

The convection heat transfer coefficient can be determined from Newton's law of cooling relation for a finned surface.

$$\dot{Q}_{\mathrm{conv}} = \eta h A_s (T_\infty - T_s) \longrightarrow h = \frac{\dot{Q}_{\mathrm{conv}}}{\eta A_s (T_\infty - T_s)} = \frac{18.6\ \mathrm{W}}{(1)(0.0118\ \mathrm{m}^2)(60-25)°\mathrm{C}} = 45.04\ \mathrm{W/m^2.°C}$$

Starting from heat transfer coefficient, Nusselt number, Reynolds number and finally free-stream velocity will be determined. We assume the flow is laminar over the entire finned surface of the transformer.

$$Nu = \frac{hL}{k} = \frac{(45.04\ \mathrm{W/m^2.°C})(0.1\,\mathrm{m})}{0.02681\ \mathrm{W/m.°C}} = 168.0$$

$$Nu = 0.664\,\mathrm{Re}_L{}^{0.5}\,\mathrm{Pr}^{1/3} \longrightarrow \mathrm{Re}_L = \frac{Nu^2}{0.664^2\,\mathrm{Pr}^{2/3}} = \frac{(168.0)^2}{(0.664)^2(0.7248)^{2/3}} = 7.932\times10^4$$

$$\mathrm{Re}_L = \frac{\mathbf{V}_\infty L}{\upsilon} \to \mathbf{V}_\infty = \frac{\mathrm{Re}_L\,\upsilon}{L} = \frac{(7.932\times10^4)(1.726\times10^{-5}\ \mathrm{m^2/s})}{0.1\,\mathrm{m}} = \mathbf{13.7\ m/s}$$

7-30 Air is blown over an aluminum plate mounted on an array of power transistors. The number of transistors that can be placed on this plate is to be determined.

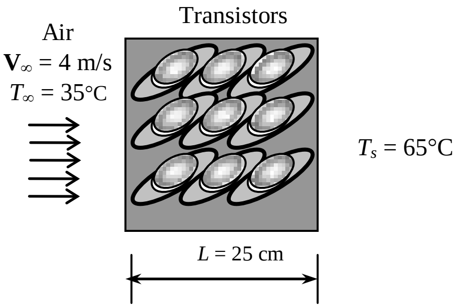
Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\mathrm{Re}_{cr} = 5\times10^5$. **3** Radiation effects are negligible **4** Heat transfer from the back side of the plate is negligible. **5** Air is an ideal gas with constant properties. **6** The local atmospheric pressure is 1 atm.

Properties The properties of air at the film temperature of $(T_s + T_\infty)/2 = (65+35)/2 = 50°\mathrm{C}$ are (Table A-15)

$$k = 0.02735\ \mathrm{W/m.°C}$$

$$\upsilon = 1.798\times10^{-5}\ \mathrm{m^2/s}$$

$$\mathrm{Pr} = 0.7228$$



Analysis The Reynolds number is

$$\mathrm{Re}_L = \frac{\mathbf{V}_\infty L}{\upsilon} = \frac{(4\ \mathrm{m/s})(0.25\ \mathrm{m})}{1.798\times10^{-5}\ \mathrm{m^2/s}} = 55{,}617$$

which is less than the critical Reynolds number (5×10^5). Thus the flow is laminar. Using the proper relation in laminar flow for Nusselt number, heat transfer coefficient and the heat transfer rate are determined to be

$$Nu = \frac{hL}{k} = 0.664\,\mathrm{Re}_L^{0.5}\,\mathrm{Pr}^{1/3} = 0.664(55{,}617)^{0.5}(0.7228)^{1/3} = 140.5$$

$$h = \frac{k}{L}Nu = \frac{0.02735\ \mathrm{W/m.°C}}{0.25\ \mathrm{m}}(140.5) = 15.37\ \mathrm{W/m^2.°C}$$

$$A_s = wL = (0.25\ \mathrm{m})(0.25\ \mathrm{m}) = 0.0625\ \mathrm{m^2}$$

$$\dot{Q}_{conv} = hA_s(T_\infty - T_s) = (15.37\ \mathrm{W/m^2.°C})(0.0625\ \mathrm{m^2})(65-35)°\mathrm{C} = 28.83\ \mathrm{W}$$

Considering that each transistor dissipates 3 W of power, the number of transistors that can be placed on this plate becomes

$$n = \frac{28.8\ \mathrm{W}}{6\ \mathrm{W}} = 4.8 \longrightarrow \mathbf{4}$$

This result is conservative since the transistors will cause the flow to be turbulent, and the rate of heat transfer to be higher.

7-31 Air is blown over an aluminum plate mounted on an array of power transistors. The number of transistors that can be placed on this plate is to be determined.

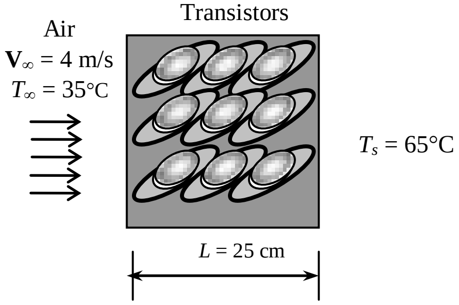
Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\mathrm{Re}_{cr} = 5\times10^5$. **3** Radiation effects are negligible **4** Heat transfer from the backside of the plate is negligible. **5** Air is an ideal gas with constant properties. **6** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the film temperature of $(T_s + T_\infty)/2 = (65+35)/2 = 50°\mathrm{C}$ are (Table A-15)

$$k = 0.02735\ \mathrm{W/m.°C}$$

$$\upsilon = 1.798\times10^{-5}\ \mathrm{m^2/s}$$

$$\mathrm{Pr} = 0.7228$$



Note that the atmospheric pressure will only affect the kinematic viscosity. The atmospheric pressure in atm is

$$P = (83.4\ \mathrm{kPa})\frac{1\ \mathrm{atm}}{101.325\ \mathrm{kPa}} = 0.823\ \mathrm{atm}$$

The kinematic viscosity at this atmospheric pressure will be

$$\upsilon = (1.798\times10^{-5}\ \mathrm{m^2/s})\,/\,0.823 = 2.184\times10^{-5}\ \mathrm{m^2/s}$$

Analysis The Reynolds number is

$$\mathrm{Re}_L = \frac{\mathbf{V}_\infty L}{\upsilon} = \frac{(4\ \mathrm{m/s})(0.25\ \mathrm{m})}{2.184\times10^{-5}\ \mathrm{m^2/s}} = 4.579\times10^4$$

which is less than the critical Reynolds number (5×10^5). Thus the flow is laminar. Using the proper relation in laminar flow for Nusselt number, the average heat transfer coefficient and the heat transfer rate are determined to be

$$Nu = \frac{hL}{k} = 0.664\,\mathrm{Re}_L^{\ 0.5}\,\mathrm{Pr}^{1/3} = 0.664(4.579\times10^4)^{0.5}(0.7228)^{1/3} = 127.5$$

$$h = \frac{k}{L}Nu = \frac{0.02735\ \mathrm{W/m.°C}}{0.25\ \mathrm{m}}(127.5) = 13.95\ \mathrm{W/m^2.°C}$$

$$A_s = wL = (0.25\ \mathrm{m})(0.25\ \mathrm{m}) = 0.0625\ \mathrm{m^2}$$

$$\dot{Q}_{\mathrm{conv}} = hA_s(T_\infty - T_s) = (13.95\ \mathrm{W/m^2.°C})(0.0625\ \mathrm{m^2})(65-35)°\mathrm{C} = 26.2\ \mathrm{W}$$

Considering that each transistor dissipates 3 W of power, the number of transistors that can be placed on this plate becomes

$$n = \frac{26.2\ \mathrm{W}}{6\ \mathrm{W}} = 4.4 \longrightarrow \mathbf{4}$$

This result is conservative since the transistors will cause the flow to be turbulent, and the rate of heat transfer to be higher.

7-32 Air is flowing over a long flat plate with a specified velocity. The distance from the leading edge of the plate where the flow becomes turbulent, and the thickness of the boundary layer at that location are to be determined.

Assumptions **1** The flow is steady and incompressible. **2** The critical Reynolds number is $\mathrm{Re}_{cr} = 5\times10^5$. **3** Air is an ideal gas. **4** The surface of the plate is smooth.

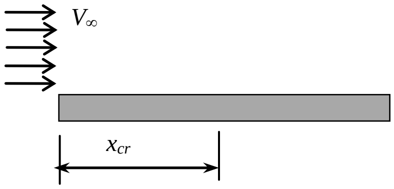
Properties The density and kinematic viscosity of air at 1 atm and 25°C are $\rho = 1.184$ kg/m^3 and $\nu = 1.562\times10^{-5}$ m^2/s (Table A-15).

Analysis The critical Reynolds number is given to be $\mathrm{Re}_{cr} = 5\times10^5$. The distance from the leading edge of the plate where the flow becomes turbulent is the distance x_{cr} where the Reynolds number becomes equal to the critical Reynolds number,

$$\mathrm{Re}_{cr} = \frac{\mathbf{V}_\infty x_{cr}}{\upsilon} \quad \rightarrow \quad x_{cr} = \frac{\nu\,\mathrm{Re}_{cr}}{\mathbf{V}_\infty} = \frac{(1.562\times10^{-5}\ \mathrm{m^2/s})(5\times10^5)}{8\ \mathrm{m/s}} = 0.976\ \mathrm{m}$$

The thickness of the boundary layer at that location is obtained by substituting this value of x into the laminar boundary layer thickness relation,

$$\delta_x = \frac{5x}{\mathrm{Re}_x^{1/2}} \quad \rightarrow \quad \delta_{cr} = \frac{5x_{cr}}{\mathrm{Re}_{cr}^{1/2}} = \frac{5(0.976\ \mathrm{m})}{(5\times10^5)^{1/2}} = 0.006903\ \mathrm{m} = \mathbf{0.69\ cm}$$



Discussion When the flow becomes turbulent, the boundary layer thickness starts to increase, and the value of its thickness can be determined from the boundary layer thickness relation for turbulent flow.

7-33 Water is flowing over a long flat plate with a specified velocity. The distance from the leading edge of the plate where the flow becomes turbulent, and the thickness of the boundary layer at that location are to be determined.

Assumptions **1** The flow is steady and incompressible. **2** The critical Reynolds number is $\mathrm{Re}_{cr} = 5\times10^5$. **3** The surface of the plate is smooth.

Properties The density and dynamic viscosity of water at 1 atm and 25°C are ρ = 997 kg/m^3 and μ = 0.891×10^{-3} kg/m·s (Table A-9).

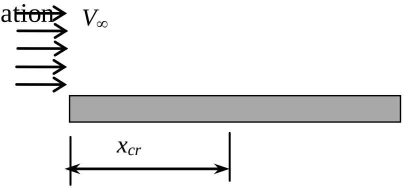
Analysis The critical Reynolds number is given to be $\mathrm{Re}_{cr} = 5\times10^5$. The distance from the leading edge of the plate where the flow becomes turbulent is the distance x_{cr} where the Reynolds number becomes equal to the critical Reynolds number,

$$\mathrm{Re}_{cr} = \frac{\rho \mathbf{V}_\infty x_{cr}}{\mu} \quad \rightarrow \quad x_{cr} = \frac{\mu\,\mathrm{Re}_{cr}}{\rho \mathbf{V}_\infty} = \frac{(0.891\times10^{-3}\ \mathrm{kg/m\cdot s})(5\times10^5)}{(997\ \mathrm{kg/m^3})(8\ \mathrm{m/s})} = 0.056\ \mathrm{m} = \mathbf{5.6\ cm}$$

The thickness of the boundary layer at that location is obtained by substituting this value of x into the laminar boundary layer thickness relation,

$$\delta_{cr} = \frac{5x}{\mathrm{Re}_x^{1/2}} \quad \rightarrow \quad \delta_{cr} = \frac{5x_{cr}}{\mathrm{Re}_{cr}^{1/2}} = \frac{5(0.056\ \mathrm{m})}{(5\times10^5)^{1/2}} = 0.00040\ \mathrm{m} = \mathbf{0.4\ mm}$$

Therefore, the flow becomes turbulent after about 5 cm from the leading edge of the plate, and the thickness of the boundary layer at that location is 0.4 mm.

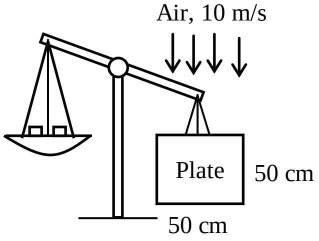


Discussion When the flow becomes turbulent, the boundary layer thickness starts to increase, and the value of its thickness can be determined from the boundary layer thickness relation for turbulent flow.

7-34 The weight of a thin flat plate exposed to air flow on both sides is balanced by a counterweight. The mass of the counterweight that needs to be added in order to balance the plate is to be determined.

Assumptions **1** The flow is steady and incompressible. **2** The critical Reynolds number is $\mathrm{Re}_{cr} = 5\times10^5$. **3** Air is an ideal gas. **4** The surfaces of the plate are smooth.

Properties The density and kinematic viscosity of air at 1 atm and 25°C are ρ = 1.184 kg/m^3 and ν = 1.562×10^{-5} m^2/s (Table A-15).



Analysis The Reynolds number is

$$\mathrm{Re}_L = \frac{\mathbf{V}_\infty L}{\upsilon} = \frac{(10\ \mathrm{m/s})(0.5\ \mathrm{m})}{1.562\times10^{-5}\ \mathrm{m^2/s}} = 3.201\times10^5$$

which is less than the critical Reynolds number of 5×10^5 . Therefore the flow is laminar. The average friction coefficient, drag force and the corresponding mass are

$$C_f = \frac{1.328}{\mathrm{Re}_L^{\ 0.5}} = \frac{1.328}{(3.201\times10^5)^{0.5}} = 0.002347$$

$$F_D = C_f A_s \frac{\rho \mathbf{V}_\infty^{\ 2}}{2} = (0.002347)[(2\times0.5\times0.5)\ \mathrm{m}^2]\frac{(1.184\ \mathrm{kg/m^3})(10\ \mathrm{m/s})^2}{2} = 0.0695\ \mathrm{kg\cdot m/s^2} = 0.0695\ \mathrm{N}$$

The mass whose weight is 0.069 N is

$$m = \frac{F_D}{g} = \frac{0.06915\ \mathrm{kg.m/s^2}}{9.81\ \mathrm{m/s^2}} = \mathbf{0.00708\ kg = 7.08\ g}$$

Therefore, the mass of the counterweight must be 7 g to counteract the drag force acting on the plate.

Discussion Note that the apparatus described in this problem provides a convenient mechanism to measure drag force and thus drag coefficient.

Flow Across Cylinders And Spheres

7-35C For the laminar flow, the heat transfer coefficient will be the highest at the stagnation point which corresponds to $\theta \approx 0°$. In turbulent flow, on the other hand, it will be highest when θ is between $90°$ and $120°$.

13-36C Turbulence moves the fluid separation point further back on the rear of the body, reducing the size of the wake, and thus the magnitude of the pressure drag (which is the dominant mode of drag). As a result, the drag coefficient suddenly drops. In general, turbulence increases the drag coefficient for flat surfaces, but the drag coefficient usually remains constant at high Reynolds numbers when the flow is turbulent.

13-37C Friction drag is due to the shear stress at the surface whereas the pressure drag is due to the pressure differential between the front and back sides of the body when a wake is formed in the rear.

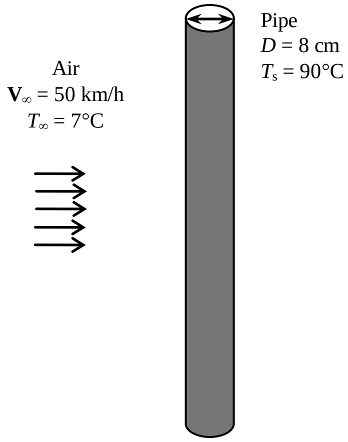
13-38C Flow separation in flow over a cylinder is delayed in turbulent flow because of the extra mixing due to random fluctuations and the transverse motion.

7-39 A steam pipe is exposed to windy air. The rate of heat loss from the steam is to be determined.√

Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties.

Properties The properties of air at 1 atm and the film temperature of $(T_s + T_\infty)/2 = (90+7)/2 = 48.5$°C are (Table A-15)

$$k = 0.02724 \text{ W/m.°C}$$
$$\upsilon = 1.784\times10^{-5} \text{ m}^2\text{/s}$$
$$\Pr = 0.7232$$



Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{[(50 \text{ km/h})(1000 \text{ m/km})/(3600 \text{ s/h})](0.08 \text{ m})}{1.784\times10^{-5} \text{ m}^2\text{/s}} = 6.228\times10^4$$

The Nusselt number corresponding to this Reynolds number is

$$Nu = \frac{hD}{k} = 0.3 + \frac{0.62\,\text{Re}^{0.5}\,\text{Pr}^{1/3}}{\left[1+(0.4/\text{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(6.228\times10^4)^{0.5}(0.7232)^{1/3}}{\left[1+(0.4/0.7232)^{2/3}\right]^{1/4}}\left[1+\left(\frac{6.228\times10^4}{282{,}000}\right)^{5/8}\right]^{4/5} = 159.1$$

The heat transfer coefficient and the heat transfer rate become

$$h = \frac{k}{D}Nu = \frac{0.02724 \text{ W/m.°C}}{0.08 \text{ m}}(159.1) = 54.17 \text{ W/m}^2\text{.°C}$$

$$A_s = \pi DL = \pi(0.08 \text{ m})(1 \text{ m}) = 0.2513 \text{ m}^2$$

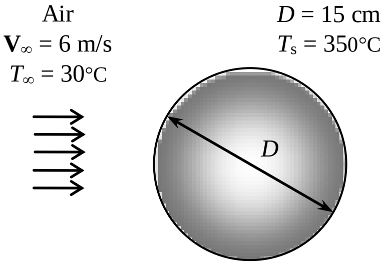
$$\dot{Q}_{conv} = hA_s(T_s - T_\infty) = (54.17 \text{ W/m}^2\text{.°C})(0.2513 \text{ m}^2)(90-7)\text{°C} = \mathbf{1130\ W} \text{ (per m length)}$$

7-40 A hot stainless steel ball is cooled by forced air. The average convection heat transfer coefficient and the cooling time are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties. **4** The outer surface temperature of the ball is uniform at all times.

Properties The average surface temperature is (350+250)/2 = 300°C, and the properties of air at 1 atm pressure and the free stream temperature of 30°C are (Table A-15)

$$k = 0.02588 \text{ W/m.°C}$$
$$\upsilon = 1.608 \times 10^{-5} \text{ m}^2\text{/s}$$
$$\mu_\infty = 1.872 \times 10^{-5} \text{ kg/m.s}$$
$$\mu_{s,@\,300\,°\text{C}} = 2.934 \times 10^{-5} \text{ kg/m.s}$$
$$\text{Pr} = 0.7282$$



Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{(6 \text{ m/s})(0.15 \text{ m})}{1.57 \times 10^{-5} \text{ m}^2\text{/s}} = 5.597 \times 10^4$$

The Nusselt number corresponding this Reynolds number is determined to be

$$Nu = \frac{hD}{k} = 2 + \left[0.4\,\text{Re}^{0.5} + 0.06\,\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2 + \left[0.4(5.597 \times 10^4)^{0.5} + 0.06(5.597 \times 10^4)^{2/3}\right](0.7282)^{0.4}\left(\frac{1.872 \times 10^{-5}}{2.934 \times 10^{-5}}\right)^{1/4} = 145.6$$

Heat transfer coefficient is

$$h = \frac{k}{D} Nu = \frac{0.02588 \text{ W/m.°C}}{0.15 \text{ m}}(145.6) = \mathbf{25.12 \text{ W/m}^2\text{.°C}}$$

The average rate of heat transfer can be determined from Newton's law of cooling by using average surface temperature of the ball

$$A_s = \pi D^2 = \pi (0.15 \text{ m})^2 = 0.07069 \text{ m}^2$$
$$\dot{Q}_{ave} = hA_s(T_s - T_\infty) = (25.12 \text{ W/m}^2\text{.°C})(0.07069 \text{ m}^2)(300 - 30)\text{°C} = 479.5 \text{ W}$$

Assuming the ball temperature to be nearly uniform , the total heat transferred from the ball during the cooling from 350 °C to 250 °C can be determined from

$$Q_{\text{total}} = mC_p(T_1 - T_2)$$

where $m = \rho V = \rho \dfrac{\pi D^3}{6} = (8055 \text{ kg/m}^3)\dfrac{\pi (0.15 \text{ m})^3}{6} = 14.23 \text{ kg}$

Therefore, $Q_{\text{total}} = mC_p(T_1 - T_2) = (14.23 \text{ kg})(480 \text{ J/kg.°C})(350 - 250)\text{°C} = 683{,}249 \text{ J}$

Then the time of cooling becomes

$$\Delta t = \frac{Q}{\dot{Q}} = \frac{683{,}249 \text{ J}}{479.5 \text{ J/s}} = 1425 \text{ s} = \mathbf{23.75 \text{ min}}$$

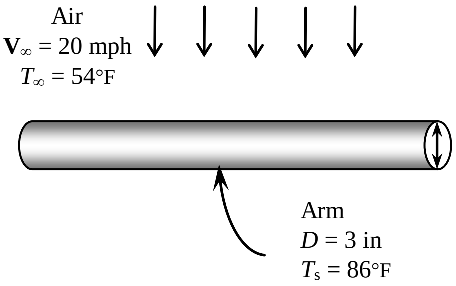
7-42E A person extends his uncovered arms into the windy air outside. The rate of heat loss from the arm is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties. 4 The arm is treated as a 2-ft-long and 3-in.-diameter cylinder with insulated ends. **5** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the film temperature of $(T_s + T_\infty)/2 = (86+54)/2 = 70°\text{F}$ are (Table A-15E)

$$k = 0.01457 \text{ Btu/h.ft.°F}$$
$$\upsilon = 0.1643\times10^{-3} \text{ ft}^2\text{/s}$$
$$\Pr = 0.7306$$



Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{[(20\times5280/3600)\text{ ft/s}](3/12)\text{ ft}}{0.1643\times10^{-3}\text{ ft}^2\text{/s}} = 4.463\times10^4$$

The Nusselt number corresponding this Reynolds number is determined to be

$$Nu = \frac{hD}{k} = 0.3 + \frac{0.62\,\text{Re}^{0.5}\,\Pr^{1/3}}{\left[1+\left(\dfrac{0.4}{\Pr}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(4.463\times10^4)^{0.5}(0.7306)^{1/3}}{\left[1+\left(\dfrac{0.4}{0.7306}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{4.463\times10^4}{282{,}000}\right)^{5/8}\right]^{4/5} = 129.6$$

Then the heat transfer coefficient and the heat transfer rate from the arm becomes

$$h = \frac{k}{D}Nu = \frac{0.01457\text{ Btu/h.ft.°F}}{(3/12)\text{ ft}}(129.6) = 7.557\text{ Btu/h.ft}^2\text{.°F}$$

$$A_s = \pi DL = \pi(3/12\text{ ft})(2\text{ ft}) = 1.571\text{ ft}^2$$

$$\dot{Q}_{conv} = hA_s(T_s - T_\infty) = (7.557\text{ Btu/h.ft}^2\text{.°F})(1.571\text{ ft}^2)(86-54)\text{°F} = \mathbf{379.8\text{ Btu/h}}$$

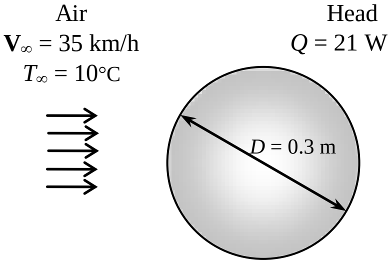
7-44 The average surface temperature of the head of a person when it is not covered and is subjected to winds is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties. **4** One-quarter of the heat the person generates is lost from the head. **5** The head can be approximated as a 30-cm-diameter sphere. **6** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm pressure and the free stream temperature of 10°C are (Table A-15)

$$k = 0.02439 \text{ W/m.°C}$$
$$\upsilon = 1.426\times10^{-5} \text{ m}^2\text{/s}$$
$$\mu_\infty = 1.778\times10^{-5} \text{ kg/m.s}$$
$$\mu_{s,@15°\text{C}} = 1.802\times10^{-5} \text{ kg/m.s}$$
$$\text{Pr} = 0.7336$$



Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{\left[(35\times1000/3600)\text{ m/s}\right](0.3\text{ m})}{1.426\times10^{-5}\text{ m}^2\text{/s}} = 2.045\times10^5$$

The proper relation for Nusselt number corresponding to this Reynolds number is

$$Nu = \frac{hD}{k} = 2 + \left[0.4\,\text{Re}^{0.5} + 0.06\,\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2 + \left[0.4(2.045\times10^5)^{0.5} + 0.06(2.045\times10^4)^{2/3}\right](0.7336)^{0.4}\left(\frac{1.778\times10^{-5}}{1.802\times10^{-5}}\right)^{1/4} = 344.7$$

The heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.02439\text{ W/m.°C}}{0.3\text{ m}}(344.7) = 28.02\text{ W/m}^2\text{.°C}$$

Then the surface temperature of the head is determined to be

$$A_s = \pi D^2 = \pi(0.3\text{ m})^2 = 0.2827\text{ m}^2$$

$$\dot{Q} = hA_s(T_s - T_\infty) \longrightarrow T_s = T_\infty + \frac{\dot{Q}}{hA_s} = 10\text{ °C} + \frac{(84/4)\text{ W}}{(28.02\text{ W/m}^2\text{.°C})(0.2827\text{ m}^2)} = \mathbf{12.7}\text{ °C}$$

7-45 The flow of a fluid across an isothermal cylinder is considered. The change in the drag force and the rate of heat transfer when the free-stream velocity of the fluid is doubled is to be determined.

Analysis The drag force on a cylinder is given by

$$F_{D1} = C_D A_N \frac{\rho \mathbf{V}_\infty{}^2}{2}$$

When the free-stream velocity of the fluid is doubled, the drag force becomes

$$F_{D2} = C_D A_N \frac{\rho (2\mathbf{V}_\infty)^2}{2}$$

Taking the ratio of them yields

$$\frac{F_{D2}}{F_{D1}} = \frac{(2\mathbf{V}_\infty)^2}{\mathbf{V}_\infty{}^2} = \mathbf{4}$$

The rate of heat transfer between the fluid and the cylinder is given by Newton's law of cooling. We assume the Nusselt number is proportional to the *n*th power of the Reynolds number with 0.33 < n < 0.805. Then,

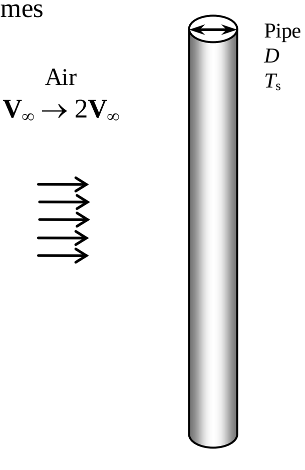
$$\begin{aligned}\dot{Q}_1 &= hA_s(T_s - T_\infty) = \left(\frac{k}{D} Nu\right) A_s(T_s - T_\infty) = \frac{k}{D}(\text{Re})^n A_s(T_s - T_\infty)\\ &= \frac{k}{D}\left(\frac{\mathbf{V}_\infty D}{\upsilon}\right)^n A_s(T_s - T_\infty)\\ &= \mathbf{V}_\infty{}^n \frac{k}{D}\left(\frac{D}{\upsilon}\right)^n A_s(T_s - T_\infty)\end{aligned}$$

When the free-stream velocity of the fluid is doubled, the heat transfer rate becomes

$$\dot{Q}_2 = (2\mathbf{V}_\infty)^n \frac{k}{D}\left(\frac{D}{\upsilon}\right)^n A(T_s - T_\infty)$$

Taking the ratio of them yields

$$\frac{\dot{Q}_2}{\dot{Q}_1} = \frac{(2\mathbf{V}_\infty)^n}{\mathbf{V}_\infty{}^n} = \mathbf{2^n}$$

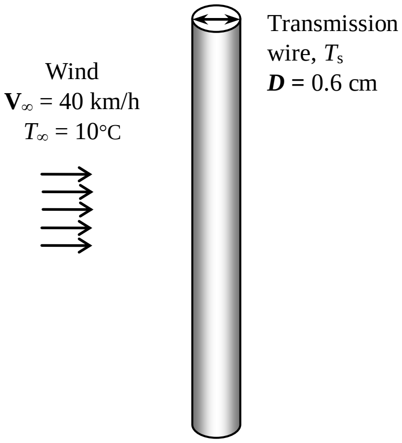


7-46 The wind is blowing across the wire of a transmission line. The surface temperature of the wire is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties. **4** The local atmospheric pressure is 1 atm.

Properties We assume the film temperature to be 10°C. The properties of air at this temperature are (Table A-15)

$$\rho = 1.246\ \text{kg/m}^3$$
$$k = 0.02439\ \text{W/m.°C}$$
$$\upsilon = 1.426\times10^{-5}\ \text{m}^2\text{/s}$$
$$\text{Pr} = 0.7336$$



Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{[(40\times1000/3600)\ \text{m/s}](0.006\ \text{m})}{1.426\times10^{-5}\ \text{m}^2\text{/s}} = 4674$$

The Nusselt number corresponding this Reynolds number is determined to be

$$Nu = \frac{hD}{k} = 0.3 + \frac{0.62\,\text{Re}^{0.5}\,\text{Pr}^{1/3}}{\left[1+(0.4/\text{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(4674)^{0.5}(0.7336)^{1/3}}{\left[1+(0.4/0.7336)^{2/3}\right]^{1/4}}\left[1+\left(\frac{4674}{282{,}000}\right)^{5/8}\right]^{4/5} = 36.0$$

The heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.02439\ \text{W/m.°C}}{0.006\ \text{m}}(36.0) = 146.3\ \text{W/m}^2\text{.°C}$$

The rate of heat generated in the electrical transmission lines per meter length is

$$\dot{W} = \dot{Q} = I^2R = (50\ \text{A})^2(0.002\ \text{Ohm}) = 5.0\ \text{W}$$

The entire heat generated in electrical transmission line has to be transferred to the ambient air. The surface temperature of the wire then becomes

$$A_s = \pi DL = \pi(0.006\ \text{m})(1\ \text{m}) = 0.01885\ \text{m}^2$$

$$\dot{Q} = hA_s(T_s - T_\infty) \longrightarrow T_s = T_\infty + \frac{\dot{Q}}{hA_s} = 10°\text{C} + \frac{5\ \text{W}}{(146.3\ \text{W/m}^2\text{.°C})(0.01885\ \text{m}^2)} = \mathbf{11.8°C}$$

7-48 An aircraft is cruising at 900 km/h. A heating system keeps the wings above freezing temperatures. The average convection heat transfer coefficient on the wing surface and the average rate of heat transfer per unit surface area are to be determined.

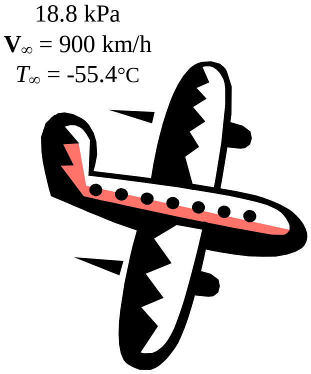
Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties. **4** The wing is approximated as a cylinder of elliptical cross section whose minor axis is 30 cm.

Properties The properties of air at 1 atm and the film temperature of $(T_s + T_\infty)/2 = (0-55.4)/2 = -27.7°\text{C}$ are (Table A-15)

$$k = 0.02152 \text{ W/m.°C}$$

$$\upsilon = 1.106 \times 10^{-5} \text{ m}^2\text{/s}$$

$$\text{Pr} = 0.7422$$



Note that the atmospheric pressure will only affect the kinematic viscosity. The atmospheric pressure in atm unit is

$$P = (18.8 \text{ kPa})\frac{1 \text{ atm}}{101.325 \text{ kPa}} = 0.1855 \text{ atm}$$

The kinematic viscosity at this atmospheric pressure is

$$\upsilon = (1.106 \times 10^{-5} \text{ m}^2\text{/s})/0.1855 = 5.961 \times 10^{-5} \text{ m}^2\text{/s}$$

Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{[(900 \times 1000/3600) \text{ m/s}](0.3 \text{ m})}{5.961 \times 10^{-5} \text{ m}^2\text{/s}} = 1.258 \times 10^6$$

The Nusselt number relation for a cylinder of elliptical cross-section is limited to Re < 15,000, and the relation below is not really applicable in this case. However, this relation is all we have for elliptical shapes, and we will use it with the understanding that the results may not be accurate.

$$Nu = \frac{hD}{k} = 0.248\,\text{Re}^{0.612}\,\text{Pr}^{1/3} = 0.248(1.258 \times 10^6)^{0.612}(0.724)^{1/3} = 1204$$

The average heat transfer coefficient on the wing surface is

$$h = \frac{k}{D}Nu = \frac{0.02152 \text{ W/m.°C}}{0.3 \text{ m}}(1204) = 86.39 \text{ W/m}^2\text{.°C}$$

Then the average rate of heat transfer per unit surface area becomes

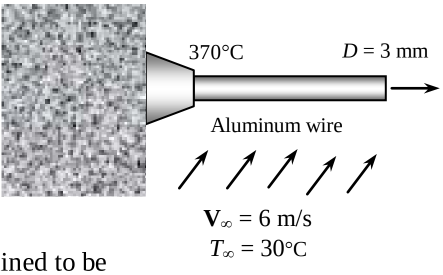
$$\dot{q} = h(T_s - T_\infty) = (86.39 \text{ W/m}^2\text{.°C})[0 - (-55.4)]\text{°C} = \mathbf{4786 \text{ W/m}^2}$$

7-49 A long aluminum wire is cooled by cross air flowing over it. The rate of heat transfer from the wire per meter length when it is first exposed to the air is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties. **4** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the film temperature of $(T_s + T_\infty)/2 = (370+30)/2 = 200°\text{C}$ are (Table A-15)

$$k = 0.03779 \text{ W/m.°C}$$
$$\upsilon = 3.455 \times 10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.6974$$



Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{(6 \text{ m/s})(0.003 \text{ m})}{3.455 \times 10^{-5} \text{ m}^2\text{/s}} = 521.0$$

The Nusselt number corresponding this Reynolds number is determined to be

$$Nu = \frac{hD}{k} = 0.3 + \frac{0.62\,\text{Re}^{0.5}\,\text{Pr}^{1/3}}{\left[1+(0.4/\text{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(521.0)^{0.5}(0.6974)^{1/3}}{\left[1+(0.4/0.6974)^{2/3}\right]^{1/4}}\left[1+\left(\frac{521.0}{282{,}000}\right)^{5/8}\right]^{4/5} = 11.48$$

Then the heat transfer coefficient and the heat transfer rate from the wire per meter length become

$$h = \frac{k}{D}Nu = \frac{0.03779 \text{ W/m.°C}}{0.003 \text{ m}}(11.48) = 144.6 \text{ W/m}^2\text{.°C}$$

$$A_s = \pi DL = \pi(0.003 \text{ m})(1 \text{ m}) = 0.009425 \text{ m}^2$$

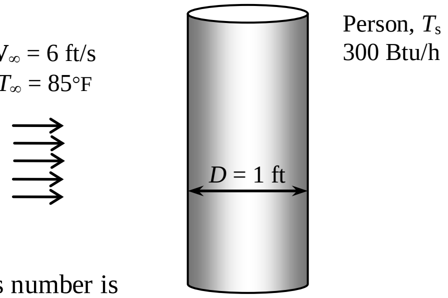
$$\dot{Q}_{conv} = hA_s(T_s - T_\infty) = (144.6 \text{ W/m}^2\text{.°C})(0.009425 \text{ m}^2)(370-30)\text{°C} = \mathbf{463.4\ W}$$

7-50E A fan is blowing air over the entire body of a person. The average temperature of the outer surface of the person is to be determined for two cases.

Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties. **4** The average human body can be treated as a 1-ft-diamter cylinder with an exposed surface area of 18 ft^2. **5** The local atmospheric pressure is 1 atm.

Properties We assume the film temperature to be $100\,°\mathrm{F}$. The properties of air at this temperature are (Table A-15E)

$$k = 0.01529\ \text{Btu/h.ft.°F}$$
$$\upsilon = 0.1809\times10^{-3}\ \text{ft}^2/\text{s}$$
$$\Pr = 0.7260$$



Analysis The Reynolds number is

$$\mathrm{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{(6\ \text{ft/s})(1\ \text{ft})}{0.1809\times10^{-3}\ \text{ft}^2/\text{s}} = 3.317\times10^4$$

The proper relation for Nusselt number corresponding this Reynolds number is

$$Nu = \frac{hD}{k} = 0.3 + \frac{0.62\,\mathrm{Re}^{0.5}\,\Pr^{1/3}}{\left[1+(0.4/\Pr)^{2/3}\right]^{1/4}}\left[1+\left(\frac{\mathrm{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(3.317\times10^4)^{0.5}(0.7260)^{1/3}}{\left[1+(0.4/0.7260)^{2/3}\right]^{1/4}}\left[1+\left(\frac{3.317\times10^4}{282{,}000}\right)^{5/8}\right]^{4/5} = 107.84$$

The heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.01529\ \text{Btu/h.ft.°F}}{(1\ \text{ft})}(107.84) = 1.649\ \text{Btu/h.ft}^2.\text{°F}$$

Then the average temperature of the outer surface of the person becomes

$$\dot{Q} = hA_s(T_s - T_\infty) \to T_s = T_\infty + \frac{\dot{Q}}{hA_s} = 85\text{°F} + \frac{300\ \text{Btu/h}}{(1.649\ \text{Btu/h.ft}^2.\text{°F})(18\ \text{ft}^2)} = \mathbf{95.1°F}$$

If the air velocity were doubled, the Reynolds number would be

$$\mathrm{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{(12\ \text{ft/s})(1\ \text{ft})}{0.1809\times10^{-3}\ \text{ft}^2/\text{s}} = 6.633\times10^4$$

The proper relation for Nusselt number corresponding this Reynolds number is

$$Nu = \frac{hD}{k} = 0.3 + \frac{0.62\,\mathrm{Re}^{0.5}\,\Pr^{1/3}}{\left[1+(0.4/\Pr)^{2/3}\right]^{1/4}}\left[1+\left(\frac{\mathrm{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(6.633\times10^4)^{0.5}(0.7260)^{1/3}}{\left[1+(0.4/0.7260)^{2/3}\right]^{1/4}}\left[1+\left(\frac{6.633\times10^4}{282{,}000}\right)^{5/8}\right]^{4/5} = 165.95$$

Heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.01529\ \text{Btu/h.ft.°F}}{(1\ \text{ft})}(165.95) = 2.537\ \text{Btu/h.ft}^2.\text{°F}$$

Then the average temperature of the outer surface of the person becomes

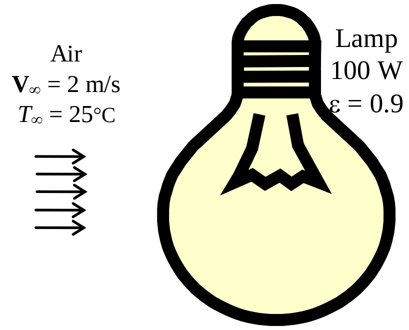
$$\dot{Q} = hA_s(T_s - T_\infty) \to T_s = T_\infty + \frac{\dot{Q}}{hA_s} = 85\text{°F} + \frac{300\ \text{Btu/h}}{(2.537\ \text{Btu/h.ft}^2.\text{°F})(18\ \text{ft}^2)} = \mathbf{91.6°F}$$

7-51 A light bulb is cooled by a fan. The equilibrium temperature of the glass bulb is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The light bulb is in spherical shape. **4** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm pressure and the free stream temperature of 25°C are (Table A-15)

$$k = 0.02551\ \text{W/m.°C}$$
$$\upsilon = 1.562\times10^{-5}\ \text{m}^2\text{/s}$$
$$\mu_\infty = 1.849\times10^{-5}\ \text{kg/m.s}$$
$$\mu_{s,@100°\text{C}} = 2.181\times10^{-5}\ \text{kg/m.s}$$
$$\text{Pr} = 0.7296$$



Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{(2\ \text{m/s})(0.1\ \text{m})}{1.562\times10^{-5}\ \text{m}^2\text{/s}} = 1.280\times10^4$$

The proper relation for Nusselt number corresponding to this Reynolds number is

$$Nu = \frac{hD}{k} = 2 + \left[0.4\,\text{Re}^{0.5} + 0.06\,\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2 + \left[0.4(1.280\times10^4)^{0.5} + 0.06(1.280\times10^4)^{2/3}\right](0.7296)^{0.4}\left(\frac{1.849\times10^{-5}}{2.181\times10^{-5}}\right)^{1/4} = 68.06$$

The heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.02551\ \text{W/m.°C}}{0.1\ \text{m}}(68.06) = 17.36\ \text{W/m}^2\text{.°C}$$

Noting that 90 % of electrical energy is converted to heat,

$$\dot{Q} = (0.90)(100\ \text{W}) = 90\ \text{W}$$

The bulb loses heat by both convection and radiation. The equilibrium temperature of the glass bulb can be determined by iteration,

$$A_s = \pi D^2 = \pi(0.1\ \text{m})^2 = 0.0314\ \text{m}^2$$

$$\dot{Q}_{\text{total}} = \dot{Q}_{conv} + \dot{Q}_{rad} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s^{\ 4} - T_{surr}^{\ 4})$$

$$90\ \text{W} = (17.36\ \text{W/m}^2\text{.°C})(0.0314\ \text{m}^2)\left[T_s - (25+273)\text{K}\right]$$
$$+ (0.9)(0.0314\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\text{.K}^4)\left[T_s^{\ 4} - (25+273\ \text{K})^4\right]$$

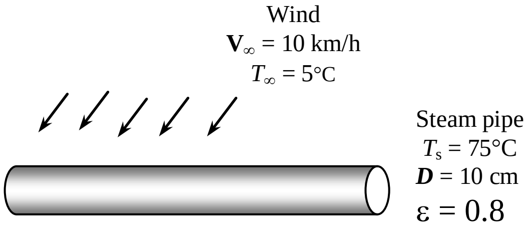
$$T_s = 406.2\ \text{K} = \mathbf{133.2°C}$$

7-52 A steam pipe is exposed to a light winds in the atmosphere. The amount of heat loss from the steam during a certain period and the money the facility will save a year as a result of insulating the steam pipe are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The plant operates every day of the year for 10 h a day. **4** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the film temperature of $(T_s + T_\infty)/2 = (75+5)/2 = 40°\text{C}$ are (Table A-15)

$$k = 0.02662 \text{ W/m.°C}$$
$$\upsilon = 1.702\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7255$$



Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{[(10\times1000/3600)\text{ m/s}](0.1\text{ m})}{1.702\times10^{-5}\text{ m}^2\text{/s}} = 1.632\times10^4$$

The Nusselt number corresponding this Reynolds number is determined to be

$$Nu = \frac{hD}{k} = 0.3 + \frac{0.62\,\text{Re}^{0.5}\,\text{Pr}^{1/3}}{\left[1+(0.4/\text{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(1.632\times10^4)^{0.5}(0.7255)^{1/3}}{\left[1+(0.4/0.7255)^{2/3}\right]^{1/4}}\left[1+\left(\frac{1.632\times10^4}{282{,}000}\right)^{5/8}\right]^{4/5} = 71.19$$

The heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.02662 \text{ W/m.°C}}{0.1\text{ m}}(71.19) = 18.95 \text{ W/m}^2\text{.°C}$$

The rate of heat loss by convection is

$$A_s = \pi DL = \pi(0.1\text{ m})(12\text{ m}) = 3.77\text{ m}^2$$
$$\dot{Q} = hA_s(T_s - T_\infty) = (18.95\text{ W/m}^2\text{.°C})(3.77\text{ m}^2)(75\text{-}5)\text{°C} = 5001\text{ W}$$

The rate of heat loss by radiation is

$$\dot{Q}_{rad} = \varepsilon A_s \sigma(T_s{}^4 - T_{surr}{}^4)$$
$$= (0.8)(3.77\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\text{.K}^4)\left[(75+273\text{ K})^4 - (0+273\text{ K})^4\right] = 1558\text{ W}$$

The total rate of heat loss then becomes

$$\dot{Q}_{\text{total}} = \dot{Q}_{conv} + \dot{Q}_{rad} = 5001 + 1558 = 6559\text{ W}$$

The amount of heat loss from the steam during a 10-hour work day is

$$Q = \dot{Q}_{total}\Delta t = (6.559\text{ kJ/s})(10\text{ h/day}\times3600\text{ s/h}) = \mathbf{2.361\times10^5\ kJ/day}$$

The total amount of heat loss from the steam per year is

$$Q_{total} = \dot{Q}_{day}(\text{no. of days}) = (2.361\times10^5\text{ kJ/day})(365\text{ days/yr}) = 8.619\times10^7\text{ kJ/yr}$$

Noting that the steam generator has an efficiency of 80%, the amount of gas used is

$$Q_{gas} = \frac{Q_{total}}{0.80} = \frac{8.619\times10^7\text{ kJ/yr}}{0.80}\left(\frac{1\text{ therm}}{105{,}500\text{ kJ}}\right) = 1021\text{ therms/yr}$$

Insulation reduces this amount by 90 %. The amount of energy and money saved becomes

$$\text{Energy saved} = (0.90)Q_{gas} = (0.90)(1021\text{ therms/yr}) = 919\text{ therms/yr}$$

$$\text{Money saved} = (\text{Energy saved})(\text{Unit cost of energy}) = (919\text{ therms/yr})(\$0.54\text{/therm}) = \mathbf{\$496}$$

7-53 A steam pipe is exposed to light winds in the atmosphere. The amount of heat loss from the steam during a certain period and the money the facility will save a year as a result of insulating the steam pipes are to be determined.

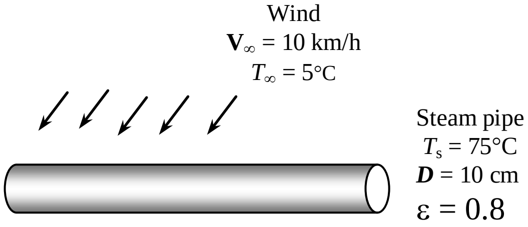
Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The plant operates every day of the year for 10 h. **4** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the film temperature of $(T_s + T_\infty)/2 = (75+5)/2 = 40°\text{C}$ are (Table A-15)

$$k = 0.02662 \text{ W/m.°C}$$

$$\upsilon = 1.702\times10^{-5} \text{ m}^2\text{/s}$$

$$\Pr = 0.7255$$



Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{[(10\times1000/3600)\text{ m/s}](0.1\text{ m})}{1.702\times10^{-5}\text{ m}^2\text{/s}} = 1.632\times10^4$$

The Nusselt number corresponding this Reynolds number is determined to be

$$Nu = \frac{hD}{k} = 0.3 + \frac{0.62\,\text{Re}^{0.5}\,\Pr^{1/3}}{\left[1+(0.4/\Pr)^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(1.632\times10^4)^{0.5}(0.7255)^{1/3}}{\left[1+(0.4/0.7255)^{2/3}\right]^{1/4}}\left[1+\left(\frac{1.632\times10^4}{282{,}000}\right)^{5/8}\right]^{4/5} = 71.19$$

The heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.02662 \text{ W/m.°C}}{0.1\text{ m}}(71.19) = 18.95 \text{ W/m}^2\text{.°C}$$

The rate of heat loss by convection is

$$A_s = \pi DL = \pi(0.1\text{ m})(12\text{ m}) = 3.77\text{ m}^2$$

$$\dot{Q} = hA_s(T_s - T_\infty) = (18.95 \text{ W/m}^2\text{.°C})(3.77\text{ m}^2)(75\text{-}5)\text{°C} = 5001\text{ W}$$

For an average surrounding temperature of 0 °C, the rate of heat loss by radiation and the total rate of heat loss are

$$\dot{Q}_{rad} = \varepsilon A_s\sigma(T_s^{\,4} - T_{surr}^{\,4})$$

$$= (0.8)(3.77\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\text{.K}^4)\left[(75+273\text{ K})^4 - (0+273\text{ K})^4\right] = 1558\text{ W}$$

$$\dot{Q}_{\text{total}} = \dot{Q}_{conv} + \dot{Q}_{rad} = 5001 + 1588 = 6559\text{ W}$$

If the average surrounding temperature is –20 °C, the rate of heat loss by radiation and the total rate of heat loss become

$$\dot{Q}_{rad} = \varepsilon A_s\sigma(T_s^{\,4} - T_{surr}^{\,4})$$

$$= (0.8)(3.77\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\text{.K}^4)\left[(75+273\text{ K})^4 - (-20+273\text{ K})^4\right]$$

$$= 1807\text{ W}$$

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad} = 5001 + 1807 = 6808\text{ W}$$

which is 6808 **-** 6559 = 249 W more than the value for a surrounding temperature of 0°C. This corresponds to

$$\%\text{change} = \frac{\dot{Q}_{\text{difference}}}{\dot{Q}_{\text{total,0°C}}}\times100 = \frac{249\text{ W}}{6559\text{ W}}\times100 = \mathbf{3.8\%} \quad \text{(increase)}$$

If the average surrounding temperature is 25°C, the rate of heat loss by radiation and the total rate of heat loss become

$$\begin{aligned}\dot{Q}_{rad} &= \varepsilon A_s \sigma (T_s{}^4 - T_{surr}{}^4) \\ &= (0.8)(3.77\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)\left[(75+273\ \text{K})^{44} - (25+273\ \text{K})^4\right] \\ &= 1159\ \text{W}\end{aligned}$$

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad} = 5001 + 1159 = 6160\ \text{W}$$

which is 6559 - 6160 = 399 W less than the value for a surrounding temperature of 0°C. This corresponds to

$$\%\text{change} = \frac{\dot{Q}_{\text{difference}}}{\dot{Q}_{\text{total,0°C}}}\times100 = \frac{399\ \text{W}}{6559\ \text{W}}\times100 = \mathbf{6.1\%}\quad\text{(decrease)}$$

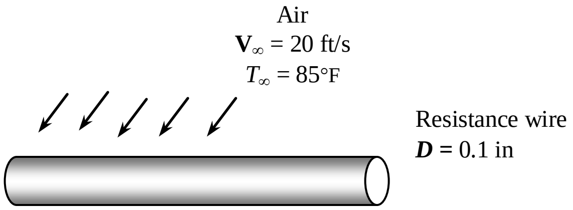
Therefore, the effect of the temperature variations of the surrounding surfaces on the total heat transfer is less than 6%.

7-54E An electrical resistance wire is cooled by a fan. The surface temperature of the wire is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties. **4** The local atmospheric pressure is 1 atm.

Properties We assume the film temperature to be $200\,^\circ\mathrm{F}$. The properties of air at this temperature are (Table A-15E)

$$k = 0.01761\ \mathrm{Btu/h.ft.^\circ F}$$
$$\upsilon = 0.2406\times 10^{-3}\ \mathrm{ft^2/s}$$
$$\mathrm{Pr} = 0.7124$$



Analysis The Reynolds number is

$$\mathrm{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{(20\ \mathrm{ft/s})(0.1/12\ \mathrm{ft})}{0.2406\times 10^{-3}\ \mathrm{ft^2/s}} = 692.8$$

The proper relation for Nusselt number corresponding this Reynolds number is

$$Nu = \frac{hD}{k} = 0.3 + \frac{0.62\,\mathrm{Re}^{0.5}\,\mathrm{Pr}^{1/3}}{\left[1+(0.4/\mathrm{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\mathrm{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(692.8)^{0.5}(0.7124)^{1/3}}{\left[1+(0.4/0.7124)^{2/3}\right]^{1/4}}\left[1+\left(\frac{692.8}{282{,}000}\right)^{5/8}\right]^{4/5} = 13.34$$

The heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.01761\ \mathrm{Btu/h.ft.^\circ F}}{(0.1/12\ \mathrm{ft})}(13.34) = 28.19\ \mathrm{Btu/h.ft^2.^\circ F}$$

Then the average temperature of the outer surface of the wire becomes

$$A_s = \pi DL = \pi(0.1/12\ \mathrm{ft})(12\ \mathrm{ft}) = 0.3142\ \mathrm{ft}^2$$

$$\dot{Q} = hA_s(T_s - T_\infty) \longrightarrow T_s = T_\infty + \frac{\dot{Q}}{hA} = 85^\circ\mathrm{F} + \frac{(1500\times 3.41214)\ \mathrm{Btu/h}}{(28.19\ \mathrm{Btu/h.ft^2.^\circ F})(0.3142\ \mathrm{ft^2})} = \mathbf{662.9^\circ F}$$

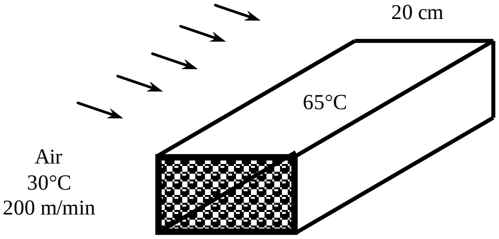
Discussion Repeating the calculations at the new film temperature of (85+662.9)/2=374°F gives T_s=668.3°F.

7-55 The components of an electronic system located in a horizontal duct is cooled by air flowing over the duct. The total power rating of the electronic device is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties. **4** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the film temperature of $(T_s + T_\infty)/2 = (65+30)/2 = 47.5°\text{C}$ are (Table A-15)

$$k = 0.02717 \text{ W/m.°C}$$
$$\upsilon = 1.774\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7235$$



Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{[(200/60)\text{ m/s}](0.2\text{ m})}{1.774\times10^{-5}\text{ m}^2\text{/s}} = 3.758\times10^4$$

Using the relation for a square duct from Table 7-1, the Nusselt number is determined to be

$$Nu = \frac{hD}{k} = 0.102\,\text{Re}^{0.675}\,\text{Pr}^{1/3} = 0.102(3.758\times10^4)^{0.675}(0.7235)^{1/3} = 112.2$$

The heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.02717\text{ W/m.°C}}{0.2\text{ m}}(112.2) = 15.24\text{ W/m}^2\text{.°C}$$

Then the rate of heat transfer from the duct becomes

$$A_s = (4\times0.2\text{ m})(1.5\text{ m}) = 1.2\text{ m}^2$$
$$\dot{Q} = hA_s(T_s - T_\infty) = (15.24\text{ W/m}^2\text{.°C})(1.2\text{ m}^2)(65-30)\text{°C} = \mathbf{640.0\ W}$$

7-56 The components of an electronic system located in a horizontal duct is cooled by air flowing over the duct. The total power rating of the electronic device is to be determined. √

Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties.

Properties The properties of air at 1 atm and the film temperature of $(T_s + T_\infty)/2 = (65+30)/2 = 47.5°\text{C}$ are (Table A-15)

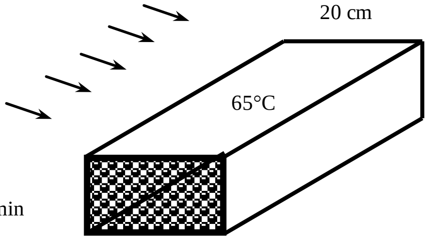
$$k = 0.02717 \text{ W/m.°C}$$

$$\upsilon = 1.774\times10^{-5} \text{ m}^2\text{/s}$$

$$\Pr = 0.7235$$

For a location at 4000 m altitude where the atmospheric pressure is 61.66 kPa, only kinematic viscosity of air will be affected. Thus,

$$\upsilon_{@61.66\text{ kPa}} = \left(\frac{101.325}{61.66}\right)(1.774\times10^{-5}) = 2.915\times10^{-5} \text{ m}^2\text{/s}$$



Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{[(200/60)\text{ m/s}](0.2\text{ m})}{2.915\times10^{-5}\text{ m}^2\text{/s}} = 2.287\times10^4$$

Using the relation for a square duct from Table 7-1, the Nusselt number is determined to be

$$Nu = \frac{hD}{k} = 0.102\,\text{Re}^{0.675}\,\Pr^{1/3} = 0.102(2.287)^{0.675}(0.7235)^{1/3} = 80.21$$

The heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.02717\text{ W/m.°C}}{0.2\text{ m}}(80.21) = 10.90\text{ W/m}^2\text{.°C}$$

Then the rate of heat transfer from the duct becomes

$$A_s = (4\times0.2\text{ m})(1.5\text{ m}) = 1.2\text{ m}^2$$

$$\dot{Q} = hA_s(T_s - T_\infty) = (10.90\text{ W/m}^2\text{.°C})(1.2\text{ m}^2)(65-30)\text{°C} = \mathbf{457.7\ W}$$

7-57 A cylindrical electronic component mounted on a circuit board is cooled by air flowing across it. The surface temperature of the component is to be determined.

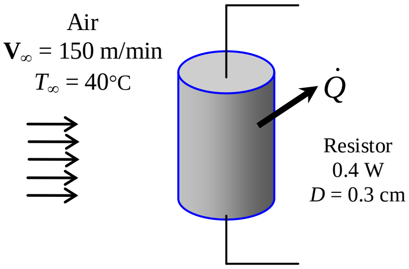
Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties. **4** The local atmospheric pressure is 1 atm.

Properties We assume the film temperature to be 50°C. The properties of air at 1 atm and at this temperature are (Table A-15)

$$k = 0.02735 \text{ W/m.°C}$$

$$\upsilon = 1.798 \times 10^{-5} \text{ m}^2\text{/s}$$

$$\text{Pr} = 0.7228$$



Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{(150/60 \text{ m/s})(0.003 \text{ m})}{1.798 \times 10^{-5} \text{ m}^2\text{/s}} = 417.1$$

The proper relation for Nusselt number corresponding to this Reynolds number is

$$Nu = \frac{hD}{k} = 0.3 + \frac{0.62\,\text{Re}^{0.5}\,\text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}}\left[1 + \left(\frac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(417.1)^{0.5}(0.7228)^{1/3}}{\left[1 + (0.4/0.7228)^{2/3}\right]^{1/4}}\left[1 + \left(\frac{417.1}{282{,}000}\right)^{5/8}\right]^{4/5} = 10.43$$

The heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.02735 \text{ W/m.°C}}{0.003 \text{ m}}(10.43) = 95.09 \text{ W/m}^2\text{.°C}$$

Then the surface temperature of the component becomes

$$A_s = \pi DL = \pi(0.003 \text{ m})(0.018 \text{ m}) = 0.0001696 \text{ m}^2$$

$$\dot{Q} = hA_s(T_s - T_\infty) \longrightarrow T_s = T_\infty + \frac{\dot{Q}}{hA} = 40 \text{ °C} + \frac{0.4 \text{ W}}{(95.09 \text{ W/m}^2\text{.°C})(0.0001696 \text{ m}^2)} = \mathbf{64.8°C}$$

7-58 A cylindrical hot water tank is exposed to windy air. The temperature of the tank after a 45-min cooling period is to be estimated.

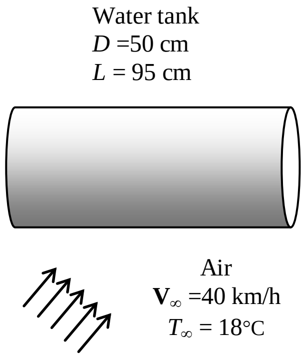
Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties. **4** The surface of the tank is at the same temperature as the water temperature. **5** The heat transfer coefficient on the top and bottom surfaces is the same as that on the side surfaces.

Properties The properties of water at 80°C are (Table A-9)

$$\rho = 971.8\ \text{kg/m}^3$$
$$C_p = 4197\ \text{J/kg.°C}$$

The properties of air at 1 atm and at the anticipated film temperature of 50°C are (Table A-15)

$$k = 0.02735\ \text{W/m.°C}$$
$$\upsilon = 1.798\times10^{-5}\ \text{m}^2\text{/s}$$
$$\text{Pr} = 0.7228$$



Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{\left(\frac{40\times1000}{3600}\ \text{m/s}\right)(0.50\ \text{m})}{1.798\times10^{-5}\ \text{m}^2\text{/s}} = 309{,}015$$

The proper relation for Nusselt number corresponding to this Reynolds number is

$$\text{Nu} = 0.3 + \frac{0.62\,\text{Re}^{0.5}\,\text{Pr}^{1/3}}{\left[1+(0.4/\text{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(309{,}015)^{0.5}(0.7228)^{1/3}}{\left[1+(0.4/0.7228)^{2/3}\right]^{1/4}}\left[1+\left(\frac{309{,}015}{282{,}000}\right)^{5/8}\right]^{4/5} = 484.9$$

The heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.02735\ \text{W/m.°C}}{0.50\ \text{m}}(484.9) = 26.53\ \text{W/m}^2\text{.°C}$$

The surface area of the tank is

$$A_s = \pi DL + 2\pi\frac{D^2}{4} = \pi(0.5)(0.95) + 2\pi(0.5)^2/4 = 1.885\ \text{m}^2$$

The rate of heat transfer is determined from

$$\dot{Q} = hA_s(T_s - T_\infty) = (26.53\ \text{W/m}^2\text{.°C})(1.885\ \text{m}^2)\left(\frac{80+T_2}{2} - 18\right)\text{°C} \qquad \text{(Eq. 1)}$$

where T_2 is the final temperature of water so that $(80+T_2)/2$ gives the average temperature of water during the cooling process. The mass of water in the tank is

$$m = \rho V = \rho\pi\frac{D^2}{4}L = (971.8\ \text{kg/m}^3)\pi(0.50\ \text{m})^2(0.95\ \text{m})/4 = 181.27\ \text{kg}$$

The amount of heat transfer from the water is determined from

$$Q = mC_p(T_2 - T_1) = (181.27\ \text{kg})(4197\ \text{J/kg.°C})(80 - T_2)\text{°C}$$

Then average rate of heat transfer is

$$\dot{Q} = \frac{Q}{\Delta t} = \frac{(181.27\ \text{kg})(4197\ \text{J/kg.°C})(80 - T_2)\text{°C}}{45\times60\ \text{s}} \qquad \text{(Eq. 2)}$$

Setting Eq. 1 to be equal to Eq. 2 we obtain the final temperature of water

$$\dot{Q} = (26.53\ \text{W/m}^2.°\text{C})(1.885\ \text{m}^2)\left(\frac{80+T_2}{2}-18\right)°\text{C} = \frac{(181.27\ \text{kg})(4197\ \text{J/kg.°C})(80 - T_2)°\text{C}}{45\times 60\ \text{s}}$$

$\longrightarrow T_2 = \mathbf{69.9°C}$

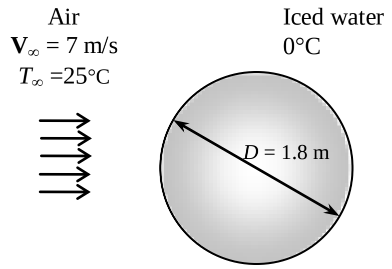
T_{w2} [C]
time [min]

7-60 Air flows over a spherical tank containing iced water. The rate of heat transfer to the tank and the rate at which ice melts are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties. **4** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm pressure and the free stream temperature of 25°C are (Table A-15)

$$k = 0.02551\ \text{W/m.°C}$$
$$\upsilon = 1.562\times10^{-5}\ \text{m}^2\text{/s}$$
$$\mu_\infty = 1.849\times10^{-5}\ \text{kg/m.s}$$
$$\mu_{s,@\,0°\text{C}} = 1.729\times10^{-5}\ \text{kg/m.s}$$
$$\text{Pr} = 0.7296$$



Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{(7\ \text{m/s})(1.8\ \text{m})}{1.562\times10^{-5}\ \text{m}^2\text{/s}} = 806{,}658$$

The proper relation for Nusselt number corresponding to this Reynolds number is

$$Nu = \frac{hD}{k} = 2 + \left[0.4\,\text{Re}^{0.5} + 0.06\,\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2 + \left[0.4(806{,}658)^{0.5} + 0.06(806{,}658)^{2/3}\right](0.7296)^{0.4}\left(\frac{1.849\times10^{-5}}{1.729\times10^{-5}}\right)^{1/4} = 790.1$$

The heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.02551\ \text{W/m.°C}}{1.8\ \text{m}}(790.1) = 11.20\ \text{W/m}^2\text{.°C}$$

Then the rate of heat transfer is determined to be

$$A_s = \pi D^2 = \pi(1.8\ \text{m})^2 = 10.18\ \text{m}^2$$
$$\dot{Q} = hA_s(T_s - T_\infty) = (11.20\ \text{W/m}^2\text{.°C})(10.18\ \text{m}^2)(25-0)\text{°C} = \mathbf{2850\ W}$$

The rate at which ice melts is

$$\dot{Q} = \dot{m}h_{fg} \longrightarrow = 2.850\ \text{kW} = \dot{m}(333.7\ \text{kJ/kg}) \longrightarrow \dot{m} = 0.00854\ \text{kg/s} = \mathbf{0.512\ kg/min}$$

7-61 A cylindrical bottle containing cold water is exposed to windy air. The average wind velocity is to be estimated.

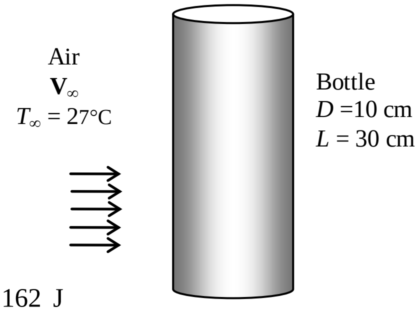
Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties. **4** Heat transfer at the top and bottom surfaces is negligible.

Properties The properties of water at the average temperature of $(T_1 + T_2)/2 = (3+11)/2 = 7°\text{C}$ are (Table A-9)

$$\rho = 999.8 \text{ kg/m}^3$$
$$C_p = 4200 \text{ J/kg.°C}$$

The properties of air at 1 atm and the film temperature of $(T_s + T_\infty)/2 = (7+27)/2 = 17°\text{C}$ are (Table A-15)

$$k = 0.02491 \text{ W/m.°C}$$
$$\upsilon = 1.489\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7317$$



Analysis The mass of water in the bottle is

$$m = \rho V = \rho\pi\frac{D^2}{4}L = (999.8 \text{ kg/m}^3)\pi(0.10 \text{ m})^2(0.30 \text{ m})/4 = 2.356 \text{ kg}$$

Then the amount of heat transfer to the water is

$$Q = mC_p(T_2 - T_1) = (2.356 \text{ kg})(4200 \text{ J/kg.°C})(11-3)°\text{C} = 79{,}162 \text{ J}$$

The average rate of heat transfer is

$$\dot{Q} = \frac{Q}{\Delta t} = \frac{79{,}162 \text{ J}}{45\times 60 \text{ s}} = 29.32 \text{ W}$$

The heat transfer coefficient is

$$A_s = \pi DL = \pi(0.10 \text{ m})(0.30 \text{ m}) = 0.09425 \text{ m}^2$$

$$\dot{Q}_{\text{conv}} = hA_s(T_s - T_\infty) \longrightarrow 29.32 \text{ W} = h(0.09425 \text{ m}^2)(27-7)°\text{C} \longrightarrow h = 15.55 \text{ W/m}^2.°\text{C}$$

The Nusselt number is

$$Nu = \frac{hD}{k} = \frac{(15.55 \text{ W/m}^2.°\text{C})(0.10 \text{ m})}{0.02491 \text{ W/m.°C}} = 62.42$$

Reynolds number can be obtained from the Nusselt number relation for a flow over the cylinder

$$Nu = 0.3 + \frac{0.62\,\text{Re}^{0.5}\,\text{Pr}^{1/3}}{\left[1+(0.4/\text{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$62.42 = 0.3 + \frac{0.62\,\text{Re}^{0.5}(0.7317)^{1/3}}{\left[1+(0.4/0.7317)^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5} \longrightarrow \text{Re} = 12{,}856$$

Then using the Reynolds number relation we determine the wind velocity

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} \longrightarrow 12{,}856 = \frac{\mathbf{V}_\infty(0.10 \text{ m})}{1.489\times10^{-5} \text{ m}^2\text{/s}} \longrightarrow \mathbf{V}_\infty = \mathbf{1.91\,m/s}$$

Flow Across Tube Banks

7-62C In tube banks, the flow characteristics are dominated by the *maximum velocity* $\mathcal{V}_{\max}$ that occurs within the tube bank rather than the approach velocity $\mathcal{V}$. Therefore, the Reynolds number is defined on the basis of maximum velocity.

7-63C The level of turbulence, and thus the heat transfer coefficient, increases with row number because of the combined effects of upstream rows in turbulence caused and the wakes formed. But there is no significant change in turbulence level after the first few rows, and thus the heat transfer coefficient remains constant. There is no change in transverse direction.

7-64 Combustion air is preheated by hot water in a tube bank. The rate of heat transfer to air and the pressure drop of air are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The surface temperature of the tubes is equal to the temperature of hot water.

Properties The exit temperature of air, and thus the mean temperature, is not known. We evaluate the air properties at the assumed mean temperature of 20°C (will be checked later) and 1 atm (Table A-15):

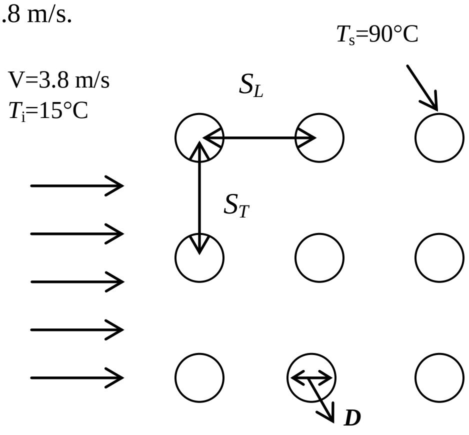
$k = 0.02514$ W/m-K $\qquad \rho = 1.204$ kg/m^3

$C_p = 1.007$ kJ/kg-K $\qquad \Pr = 0.7309$

$\mu = 1.825\times10^{-5}$ kg/m-s $\qquad \Pr_s = \Pr_{@\,Ts} = 0.7132$

Also, the density of air at the inlet temperature of 15°C (for use in the mass flow rate calculation at the inlet) is $\rho_i = 1.225$ kg/m^3.

Analysis It is given that $D = 0.021$ m, $S_L = S_T = 0.05$ m, and V = 3.8 m/s. Then the maximum velocity and the Reynolds number based on the maximum velocity become



$$\mathrm{V}_{\max} = \frac{S_T}{S_T - D}\mathrm{V} = \frac{0.05}{0.05-0.021}(3.8\text{ m/s}) = 6.552\text{ m/s}$$

$$\mathrm{Re}_D = \frac{\rho \mathrm{V}_{\max} D}{\mu} = \frac{(1.204\text{ kg/m}^3)(6.552\text{ m/s})(0.021\text{ m})}{1.825\times10^{-5}\text{ kg/m}\cdot\text{s}} = 9075$$

The average Nusselt number is determined using the proper relation from Table 7-2 to be

$$\begin{aligned}\mathrm{Nu}_D &= 0.27\,\mathrm{Re}_D^{0.63}\,\Pr^{0.36}(\Pr/\Pr_s)^{0.25}\\ &= 0.27(9075)^{0.63}(0.7309)^{0.36}(0.7309/0.7132)^{0.25} = 75.59\end{aligned}$$

This Nusselt number is applicable to tube banks with $N_L > 16$. In our case the number of rows is $N_L = 8$, and the corresponding correction factor from Table 7-3 is $F = 0.967$. Then the average Nusselt number and heat transfer coefficient for all the tubes in the tube bank become

$$\mathrm{Nu}_{D,N_L} = F\mathrm{Nu}_D = (0.967)(75.59) = 73.1$$

$$h = \frac{Nu_{D,N_L}\,k}{D} = \frac{73.1(0.02514\text{ W/m}\cdot°\text{C})}{0.021\text{ m}} = 87.5\text{ W/m}^2\cdot°\text{C}$$

The total number of tubes is $N = N_L \times N_T = 8\times8 = 64$. For a unit tube length (L = 1 m), the heat transfer surface area and the mass flow rate of air (evaluated at the inlet) are

$$A_s = N\pi DL = 64\pi(0.021\text{ m})(1\text{ m}) = 4.222\ \text{m}^2$$

$$\dot{m} = \dot{m}_i = \rho_i \mathsf{V}(N_T S_T L) = (1.225\ \text{kg/m}^3)(3.8\ \text{m/s})(8)(0.05\ \text{m})(1\ \text{m}) = 1.862\ \text{kg/s}$$

Then the fluid exit temperature, the log mean temperature difference, and the rate of heat transfer become

$$T_e = T_s - (T_s - T_i)\exp\left(-\frac{A_s h}{\dot{m}C_p}\right) = 90 - (90 - 15)\exp\left(-\frac{(4.222\ \text{m}^2)(87.5\ \text{W/m}^2\cdot{}^\circ\text{C})}{(1.862\ \text{kg/s})(1007\ \text{J/kg}\cdot{}^\circ\text{C})}\right) = 28.42^\circ\text{C}$$

$$\Delta T_{\ln} = \frac{(T_s - T_i) - (T_s - T_e)}{\ln[(T_s - T_i)/(T_s - T_e)]} = \frac{(90 - 15) - (90 - 28.42)}{\ln[(90 - 15)/(90 - 28.42)]} = 68.07^\circ\text{C}$$

$$\dot{Q} = hA_s\Delta T_{\ln} = (87.5\ \text{W/m}^2\cdot{}^\circ\text{C})(4.222\ \text{m}^2)(68.07^\circ\text{C}) = \mathbf{25{,}148\ W}$$

For this square in-line tube bank, the friction coefficient corresponding to Re_D = 9075 and S_L/D = 5/2.1 = 2.38 is, from Fig. 7-27a, f = 0.22. Also, χ = 1 for the square arrangements. Then the pressure drop across the tube bank becomes

$$\Delta P = N_L f\chi \frac{\rho \mathsf{V}_{\max}^2}{2} = 8(0.22)(1)\frac{(1.204\ \text{kg/m}^3)(6.552\ \text{m/s})^2}{2}\left(\frac{1\ \text{N}}{1\ \text{kg}\cdot\text{m/s}^2}\right) = \mathbf{45.5\ \ Pa}$$

Discussion The arithmetic mean fluid temperature is $(T_i + T_e)/2$ = (15 + 29.1)/2 = 22.1°C, which is fairly close to the assumed value of 20°C. Therefore, there is no need to repeat calculations.

7-65 Combustion air is preheated by hot water in a tube bank. The rate of heat transfer to air and the pressure drop of air are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The surface temperature of the tubes is equal to the temperature of hot water.

Properties The exit temperature of air, and thus the mean temperature, is not known. We evaluate the air properties at the assumed mean temperature of 20°C (will be checked later) and 1 atm (Table A-15):

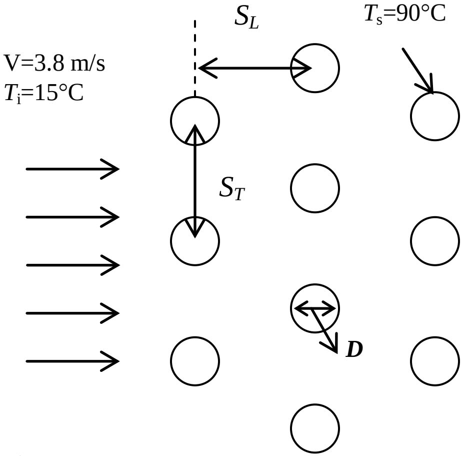
$k = 0.02514$ W/m-K　　　　$\rho = 1.204$ kg/m^3

$C_p = 1.007$ kJ/kg-K　　　　Pr = 0.7309

$\mu = 1.825\times10^{-5}$ kg/m-s　　　　$\text{Pr}_s = \text{Pr}_{@\,Ts} = 0.7132$

Also, the density of air at the inlet temperature of 15°C (for use in the mass flow rate calculation at the inlet) is $\rho_i = 1.225$ kg/m^3.

Analysis It is given that $D = 0.021$ m, $S_L = S_T = 0.05$ m, and V = 3.8 m/s. Then the maximum velocity and the Reynolds number based on the maximum velocity become



$$\text{V}_{\max} = \frac{S_T}{S_T - D}\text{V} = \frac{0.05}{0.05-0.021}(3.8\text{ m/s}) = 6.552\text{ m/s}$$

since $S_D > (S_T + D)/2$

$$\text{Re}_D = \frac{\rho \text{V}_{\max} D}{\mu} = \frac{(1.204\text{ kg/m}^3)(6.552\text{ m/s})(0.021\text{ m})}{1.825\times10^{-5}\text{ kg/m}\cdot\text{s}} = 9075$$

The average Nusselt number is determined using the proper relation from Table 7-2 to be

$$\begin{aligned}\text{Nu}_D &= 0.35(S_T/S_L)^{0.2}\,\text{Re}_D^{0.6}\,\text{Pr}^{0.36}(\text{Pr}/\text{Pr}_s)^{0.25}\\ &= 0.35(0.05/0.05)^{0.2}(9075)^{0.6}(0.7309)^{0.36}(0.7309/0.7132)^{0.25} = 74.55\end{aligned}$$

This Nusselt number is applicable to tube banks with $N_L > 16$. In our case the number of rows is $N_L = 8$, and the corresponding correction factor from Table 7-3 is $F = 0.967$. Then the average Nusselt number and heat transfer coefficient for all the tubes in the tube bank become

$$\text{Nu}_{D,N_L} = F\text{Nu}_D = (0.967)(74.55) = 72.09$$

$$h = \frac{Nu_{D,N_L}k}{D} = \frac{72.09(0.02514\text{ W/m}\cdot°\text{C})}{0.021\text{ m}} = 86.29\text{ W/m}^2\cdot°\text{C}$$

The total number of tubes is $N = N_L \times N_T = 8\times8 = 64$. For a unit tube length ($L = 1$ m), the heat transfer surface area and the mass flow rate of air (evaluated at the inlet) are

$$A_s = N\pi DL = 64\pi(0.021\text{ m})(1\text{ m}) = 4.222\ \text{m}^2$$

$$\dot{m} = \dot{m}_i = \rho_i\text{V}(N_T S_T L) = (1.225\text{ kg/m}^3)(3.8\text{ m/s})(8)(0.05\text{ m})(1\text{ m}) = 1.862\text{ kg/s}$$

Then the fluid exit temperature, the log mean temperature difference, and the rate of heat transfer become

$$T_e = T_s - (T_s - T_i)\exp\left(-\frac{A_s h}{\dot{m}C_p}\right) = 90-(90-15)\exp\left(-\frac{(4.222\text{ m}^2)(86.29\text{ W/m}^2\cdot°\text{C})}{(1.862\text{ kg/s})(1007\text{ J/kg}\cdot°\text{C})}\right) = 28.25°\text{C}$$

$$\Delta T_{\ln} = \frac{(T_s - T_i)-(T_s - T_e)}{\ln[(T_s-T_i)/(T_s-T_e)]} = \frac{(90-15)-(90-28.25)}{\ln[(90-15)/(90-28.25)]} = 68.16°\text{C}$$

$$\dot{Q} = hA_s\Delta T_{\ln} = (86.29\text{ W/m}^2\cdot°\text{C})(4.222\text{ m}^2)(68.16°\text{C}) = \mathbf{24{,}834\ W}$$

For this staggered tube bank, the friction coefficient corresponding to $\text{Re}_D = 9075$ and $S_T/D = 5/2.1 = 2.38$ is, from Fig. 7-27ba, $f = 0.34$. Also, $\chi = 1$ for the square arrangements. Then the pressure drop across the tube bank becomes

$$\Delta P = N_L f\chi \frac{\rho V_{\max}^2}{2} = 8(0.34)(1)\frac{(1.204\text{ kg/m}^3)(6.552\text{ m/s})^2}{2}\left(\frac{1\text{ N}}{1\text{ kg}\cdot\text{m/s}^2}\right) = \mathbf{70.3\ Pa}$$

Discussion The arithmetic mean fluid temperature is $(T_i + T_e)/2 = (15 + 28.3)/2 = 21.7°\text{C}$, which is fairly close to the assumed value of 20°C. Therefore, there is no need to repeat calculations.

7-66 Combustion air is heated by condensing steam in a tube bank. The rate of heat transfer to air, the pressure drop of air, and the rate of condensation of steam are to be determined.

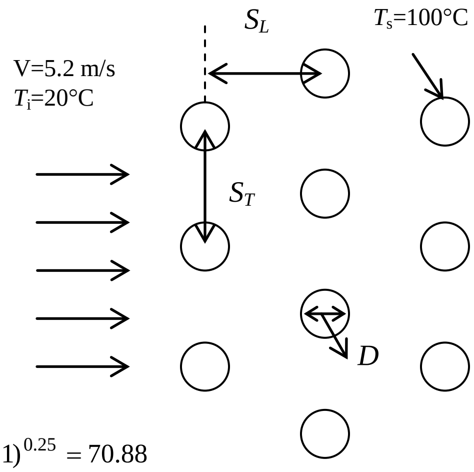
Assumptions **1** Steady operating conditions exist. **2** The surface temperature of the tubes is equal to the temperature of steam.

Properties The exit temperature of air, and thus the mean temperature, is not known. We evaluate the air properties at the assumed mean temperature of 35°C (will be checked later) and 1 atm (Table A-15):

$k = 0.02625$ W/m-K	$\rho = 1.145$ kg/m^3
$C_p = 1.007$ kJ/kg-K	Pr = 0.7268
$\mu = 1.895\times10^{-5}$ kg/m-s	$\text{Pr}_s = \text{Pr}_{@\,T_s} = 0.7111$

Also, the density of air at the inlet temperature of 20°C (for use in the mass flow rate calculation at the inlet) is $\rho_i = 1.204$ kg/m^3. The enthalpy of vaporization of water at 100°C is $h_{fg} = 2257$ kJ/kg-K (Table A-9).

Analysis (*a*) It is given that $D = 0.016$ m, $S_L = S_T = 0.04$ m, and V = 5.2 m/s. Then the maximum velocity and the Reynolds number based on the maximum velocity become



$$V_{\max} = \frac{S_T}{S_T - D}V = \frac{0.04}{0.04 - 0.016}(5.2\text{ m/s}) = 8.667\text{ m/s}$$

since $S_D > (S_T + D)/2$

$$\text{Re}_D = \frac{\rho V_{\max} D}{\mu} = \frac{(1.145\text{ kg/m}^3)(8.667\text{ m/s})(0.016\text{ m})}{1.895\times10^{-5}\text{ kg/m}\cdot\text{s}} = 8380$$

The average Nusselt number is determined using the proper relation from Table 7-2 to be

$$\begin{aligned}\text{Nu}_D &= 0.35(S_T/S_L)^{0.2}\,\text{Re}_D^{0.6}\,\text{Pr}^{0.36}(\text{Pr}/\text{Pr}_s)^{0.25}\\ &= 0.35(0.04/0.04)^{0.2}(8380)^{0.6}(0.7268)^{0.36}(0.7268/0.7111)^{0.25} = 70.88\end{aligned}$$

Since $N_L = 20$, which is greater than 16, the average Nusselt number and heat transfer coefficient for all the tubes in the tube bank become

$$\text{Nu}_{D,N_L} = \text{Nu}_D = 70.88$$

$$h = \frac{Nu_{D,N_L}\,k}{D} = \frac{70.88(0.02625\text{ W/m}\cdot°\text{C})}{0.016\text{ m}} = 116.3\text{ W/m}^2\cdot°\text{C}$$

The total number of tubes is $N = N_L \times N_T = 20\times10 = 200$. For a unit tube length ($L = 1$ m), the heat transfer surface area and the mass flow rate of air (evaluated at the inlet) are

$$A_s = N\pi DL = 200\pi(0.016\text{ m})(1\text{ m}) = 10.05\text{ m}^2$$

$$\dot{m} = \dot{m}_i = \rho_i \mathrm{V}(N_T S_T L) = (1.204\ \mathrm{kg/m^3})(5.2\ \mathrm{m/s})(10)(0.04\ \mathrm{m})(1\ \mathrm{m}) = 2.504\ \mathrm{kg/s}$$

Then the fluid exit temperature, the log mean temperature difference, and the rate of heat transfer become

$$T_e = T_s - (T_s - T_i)\exp\left(-\frac{A_s h}{\dot{m}C_p}\right) = 100 - (100-20)\exp\left(-\frac{(10.05\ \mathrm{m^2})(116.3\ \mathrm{W/m^2\cdot{}^\circ C})}{(2.504\ \mathrm{kg/s})(1007\ \mathrm{J/kg\cdot{}^\circ C})}\right) = 49.68^\circ\mathrm{C}$$

$$\Delta T_{\ln} = \frac{(T_s - T_i) - (T_s - T_e)}{\ln[(T_s - T_i)/(T_s - T_e)]} = \frac{(100-20)-(100-49.68)}{\ln[(100-20)/(100-49.68)]} = 64.01^\circ\mathrm{C}$$

$$\dot{Q} = hA_s\Delta T_{\ln} = (116.3\ \mathrm{W/m^2\cdot{}^\circ C})(10.05\ \mathrm{m^2})(64.01^\circ\mathrm{C}) = \mathbf{74{,}836\ W}$$

(*b*) For this staggered tube bank, the friction coefficient corresponding to $\mathrm{Re}_D = 7713$ and $S_T/D = 4/1.6 = 2.5$ is, from Fig. 7-27b, $f = 0.33$. Also, $\chi = 1$ for the square arrangements. Then the pressure drop across the tube bank becomes

$$\Delta P = N_L f\chi \frac{\rho \mathrm{V}_{\max}^2}{2} = 20(0.33)(1)\frac{(1.145\ \mathrm{kg/m^3})(8.667\ \mathrm{m/s})^2}{2}\left(\frac{1\ \mathrm{N}}{1\ \mathrm{kg\cdot m/s^2}}\right) = \mathbf{283.9\ \ Pa}$$

(*c*) The rate of condensation of steam is

$$\dot{Q} = \dot{m}_{\mathrm{cond}} h_{fg@100^\circ\mathrm{C}} \longrightarrow \dot{m}_{\mathrm{cond}} = \frac{\dot{Q}}{h_{fg@100^\circ\mathrm{C}}} = \frac{74.836\ \mathrm{kW}}{2257\ \mathrm{kJ/kg\cdot{}^\circ C}} = \mathbf{0.03316\ kg/s}$$

Discussion The arithmetic mean fluid temperature is $(T_i + T_e)/2 = (20 + 49.7)/2 = 34.9^\circ\mathrm{C}$, which is very close to the assumed value of 35°C. Therefore, there is no need to repeat calculations.

7-67 Combustion air is heated by condensing steam in a tube bank. The rate of heat transfer to air, the pressure drop of air, and the rate of condensation of steam are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The surface temperature of the tubes is equal to the temperature of steam.

Properties The exit temperature of air, and thus the mean temperature, is not known. We evaluate the air properties at the assumed mean temperature of 35°C (will be checked later) and 1 atm (Table A-15):

$k = 0.02625$ W/m-K $\quad\quad \rho = 1.145$ kg/m^3

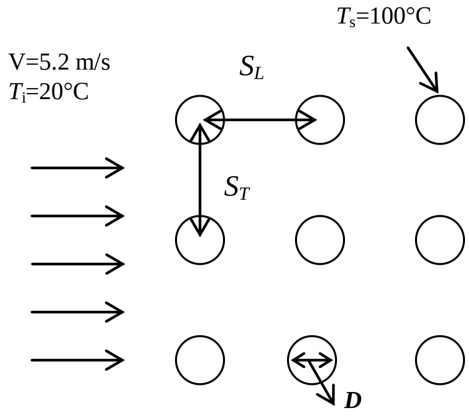
$C_p = 1.007$ kJ/kg-K $\quad\quad \mathrm{Pr} = 0.7268$

$\mu = 1.895\times10^{-5}$ kg/m-s $\quad\quad \mathrm{Pr}_s = \mathrm{Pr}_{@\,Ts} = 0.7111$

Also, the density of air at the inlet temperature of 20°C (for use in the mass flow rate calculation at the inlet) is $\rho_i = 1.204$ kg/m^3. The enthalpy of vaporization of water at 100°C is $h_{fg} = 2257$ kJ/kg-K (Table A-9).

Analysis (*a*) It is given that $D = 0.016$ m, $S_L = S_T = 0.05$ m, and V = 5.2 m/s.

Then the maximum velocity and the Reynolds number based on the maximum velocity become



$$\mathrm{V}_{\max} = \frac{S_T}{S_T - D}\mathrm{V} = \frac{0.05}{0.05 - 0.016}(5.2\text{ m/s}) = 7.647\text{ m/s}$$

$$\mathrm{Re}_D = \frac{\rho \mathrm{V}_{\max} D}{\mu} = \frac{(1.145\text{ kg/m}^3)(7.647\text{ m/s})(0.016\text{ m})}{1.895\times10^{-5}\text{ kg/m}\cdot\text{s}} = 7394$$

The average Nusselt number is determined using the proper relation from Table 7-2 to be

$$\begin{aligned}\mathrm{Nu}_D &= 0.27\,\mathrm{Re}_D^{0.63}\,\mathrm{Pr}^{0.36}(\mathrm{Pr}/\mathrm{Pr}_s)^{0.25} \\ &= 0.27(7394)^{0.63}(0.7268)^{0.36}(0.7268/0.7111)^{0.25} = 66.26\end{aligned}$$

Since N_L =20, which is greater than 16, the average Nusselt number and heat transfer coefficient for all the tubes in the tube bank become

$$\mathrm{Nu}_{D,N_L} = \mathrm{Nu}_D = 66.26$$

$$h = \frac{Nu_{D,N_L}k}{D} = \frac{66.26(0.02625\text{ W/m}\cdot°\text{C})}{0.016\text{ m}} = 108.7\text{ W/m}^2\cdot°\text{C}$$

The total number of tubes is $N = N_L \times N_T = 20\times10 = 200$. For a unit tube length (L = 1 m), the heat transfer surface area and the mass flow rate of air (evaluated at the inlet) are

$$A_s = N\pi DL = 200\pi(0.016\text{ m})(1\text{ m}) = 10.05\text{ m}^2$$

$$\dot{m} = \dot{m}_i = \rho_i \mathrm{V}(N_T S_T L) = (1.204\text{ kg/m}^3)(5.2\text{ m/s})(10)(0.05\text{ m})(1\text{ m}) = 3.130\text{ kg/s}$$

Then the fluid exit temperature, the log mean temperature difference, and the rate of heat transfer become

$$T_e = T_s - (T_s - T_i)\exp\left(-\frac{A_s h}{\dot{m}C_p}\right) = 100 - (100-20)\exp\left(-\frac{(10.05\text{ m}^2)(108.7\text{ W/m}^2\cdot°\text{C})}{(3.130\text{ kg/s})(1007\text{ J/kg}\cdot°\text{C})}\right) = 43.44°\text{C}$$

$$\Delta T_{\ln} = \frac{(T_s - T_i) - (T_s - T_e)}{\ln[(T_s - T_i)/(T_s - T_e)]} = \frac{(100-20)-(100-43.44)}{\ln[(100-20)/(100-43.44)]} = 67.6°\text{C}$$

$$\dot{Q} = hA_s\Delta T_{\ln} = (108.7\text{ W/m}^2\cdot°\text{C})(10.05\text{ m}^2)(67.6°\text{C}) = \mathbf{73{,}882\ W}$$

(*b*) For this in-line arrangement tube bank, the friction coefficient corresponding to Re_D = 6806 and S_L/D = 5/1.6 = 3.125 is, from Fig. 7-27a, f = 0.20. Also, χ = 1 for the square arrangements. Then the pressure drop across the tube bank becomes

$$\Delta P = N_L f\chi \frac{\rho V_{\max}^2}{2} = 20(0.20)(1)\frac{(1.145\ \mathrm{kg/m^3})(7.647\ \mathrm{m/s})^2}{2}\left(\frac{1\ \mathrm{N}}{1\ \mathrm{kg\cdot m/s^2}}\right) = \mathbf{133.9\ \ Pa}$$

(*c*) The rate of condensation of steam is

$$\dot{Q} = \dot{m}_{\mathrm{cond}} h_{fg\,@100°\mathrm{C}} \longrightarrow \dot{m}_{\mathrm{cond}} = \frac{\dot{Q}}{h_{fg\,@100°\mathrm{C}}} = \frac{73.882\ \mathrm{kW}}{2257\ \mathrm{kJ/kg\cdot °C}} = \mathbf{0.03273\ kg/s}$$

Discussion The arithmetic mean fluid temperature is $(T_i + T_e)/2$ = (20 + 43.4)/2 = 31.7°C, which is fairly close to the assumed value of 35°C. Therefore, there is no need to repeat calculations.

7-68 Water is preheated by exhaust gases in a tube bank. The rate of heat transfer, the pressure drop of exhaust gases, and the temperature rise of water are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The surface temperature of the tubes is equal to the temperature of steam. **3** For exhaust gases, air properties are used.

Properties The exit temperature of air, and thus the mean temperature, is not known. We evaluate the air properties at the assumed mean temperature of 250°C (will be checked later) and 1 atm (Table A-15):

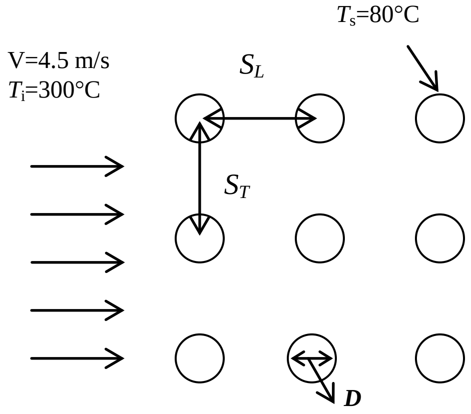
$k = 0.04104$ W/m-K $\qquad \rho = 0.6746$ kg/m^3

$C_p = 1.033$ kJ/kg-K $\qquad \Pr = 0.6946$

$\mu = 2.76\times10^{-5}$ kg/m-s $\qquad \Pr_s = \Pr_{@\,Ts} = 0.7154$

Also, the density of air at the inlet temperature of 300°C (for use in the mass flow rate calculation at the inlet) is $\rho_i = 0.6158$ kg/m^3.

Analysis (*a*) It is given that $D = 0.021$ m, $S_L = S_T = 0.08$ m, and V = 4.5 m/s. Then the maximum velocity and the Reynolds number based on the maximum velocity become



$$\mathrm{V}_{\max} = \frac{S_T}{S_T - D}\mathrm{V} = \frac{0.08}{0.08 - 0.021}(4.5\text{ m/s}) = 6.102\text{ m/s}$$

$$\mathrm{Re}_D = \frac{\rho \mathrm{V}_{\max} D}{\mu} = \frac{(0.6746\text{ kg/m}^3)(6.102\text{ m/s})(0.021\text{ m})}{2.76\times10^{-5}\text{ kg/m}\cdot\text{s}} = 3132$$

The average Nusselt number is determined using the proper relation from Table 7-2 to be

$$\begin{aligned}\mathrm{Nu}_D &= 0.27\,\mathrm{Re}_D^{0.63}\,\Pr^{0.36}(\Pr/\Pr_s)^{0.25}\\ &= 0.27(3132)^{0.63}(0.6946)^{0.36}(0.6946/0.7154)^{0.25} = 37.46\end{aligned}$$

Since N_L =16, the average Nusselt number and heat transfer coefficient for all the tubes in the tube bank become

$$\mathrm{Nu}_{D,N_L} = \mathrm{Nu}_D = 37.46$$

$$h = \frac{Nu_{D,N_L}k}{D} = \frac{37.46(0.04104\text{ W/m}\cdot°\text{C})}{0.021\text{ m}} = 73.2\text{ W/m}^2\cdot°\text{C}$$

The total number of tubes is $N = N_L \times N_T = 16\times8 = 128$. For a unit tube length (L = 1 m), the heat transfer surface area and the mass flow rate of air (evaluated at the inlet) are

$$A_s = N\pi DL = 128\pi(0.021\text{ m})(1\text{ m}) = 8.445\ \text{m}^2$$

$$\dot m = \dot m_i = \rho_i \mathrm{V}(N_T S_T L) = (0.6158\text{ kg/m}^3)(4.5\text{ m/s})(8)(0.08\text{ m})(1\text{ m}) = 1.773\text{ kg/s}$$

Then the fluid exit temperature, the log mean temperature difference, and the rate of heat transfer become

$$T_e = T_s - (T_s - T_i)\exp\left(-\frac{A_s h}{\dot m C_p}\right) = 80 - (80-300)\exp\left(-\frac{(8.445\text{ m}^2)(73.2\text{ W/m}^2\cdot°\text{C})}{(1.773\text{ kg/s})(1033\text{ J/kg}\cdot°\text{C})}\right) = 237.0°\text{C}$$

$$\Delta T_{\ln} = \frac{(T_s - T_i) - (T_s - T_e)}{\ln[(T_s - T_i)/(T_s - T_e)]} = \frac{(80-300)-(80-237)}{\ln[(80-300)/(80-237)]} = 186.7°\text{C}$$

$$\dot Q = hA_s\Delta T_{\ln} = (73.2\text{ W/m}^2\cdot°\text{C})(8.445\text{ m}^2)(186.7°\text{C}) = \mathbf{115{,}425\ W}$$

(*b*) For this in-line arrangement tube bank, the friction coefficient corresponding to $\mathrm{Re}_D = 3132$ and $S_L/D = 8/2.1 = 3.81$ is, from Fig. 7-27a, $f = 0.18$. Also, $\chi = 1$ for the square arrangements. Then the pressure drop across the tube bank becomes

$$\Delta P = N_L f\chi \frac{\rho V_{\max}^2}{2} = 16(0.18)(1)\frac{(0.6746\ \text{kg/m}^3)(6.102\ \text{m/s})^2}{2}\left(\frac{1\ \text{N}}{1\ \text{kg}\cdot\text{m/s}^2}\right) = \mathbf{36.2\ \ Pa}$$

(*c*) The temperature rise of water is

$$\dot{Q} = \dot{m}_{\text{water}} C_{p,water} \Delta T_{water} \longrightarrow \Delta T_{water} = \frac{\dot{Q}}{\dot{m}_{\text{water}} C_{p,water}} = \frac{115.425\ \text{kW}}{(6\ \text{kg/s})(4.18\ \text{kJ/kg}\cdot{}^\circ\text{C})} = \mathbf{4.6^\circ C}$$

Discussion The arithmetic mean fluid temperature is $(T_i + T_e)/2 = (300 + 237)/2 = 269$°C, which is sufficiently close to the assumed value of 250°C. Therefore, there is no need to repeat calculations.

7-69 Water is heated by a bundle of resistance heater rods. The number of tube rows is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The surface temperature of the rods is constant.

Properties The properties of water at the mean temperature of (15°C +65°C)/2=40°C are (Table A-9):

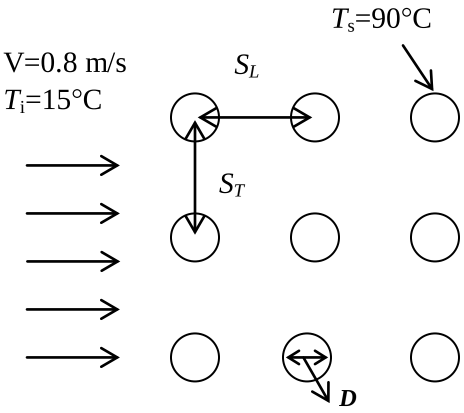
$k = 0.631$ W/m-K $\quad\rho = 992.1$ kg/m^3

$C_p = 4.179$ kJ/kg-K $\quad \Pr = 4.32$

$\mu = 0.653\times10^{-3}$ kg/m-s $\quad \Pr_s = \Pr_{@\,Ts} = 1.96$

Also, the density of water at the inlet temperature of 15°C (for use in the mass flow rate calculation at the inlet) is ρ_i =999.1 kg/m^3.

Analysis It is given that $D = 0.01$ m, $S_L = 0.04$ m and $S_T = 0.03$ m, and V = 0.8 m/s. Then the maximum velocity and the Reynolds number based on the maximum velocity become



$$\mathrm{V}_{\max} = \frac{S_T}{S_T - D}\mathrm{V} = \frac{0.03}{0.03-0.01}(0.8\text{ m/s}) = 1.20\text{ m/s}$$

$$\mathrm{Re}_D = \frac{\rho \mathrm{V}_{\max} D}{\mu} = \frac{(992.1\text{ kg/m}^3)(1.20\text{ m/s})(0.01\text{ m})}{0.653\times10^{-3}\text{ kg/m}\cdot\text{s}} = 18{,}232$$

The average Nusselt number is determined using the proper relation from Table 7-2 to be

$$\begin{aligned}\mathrm{Nu}_D &= 0.27\,\mathrm{Re}_D^{0.63}\Pr^{0.36}(\Pr/\Pr_s)^{0.25}\\ &= 0.27(18{,}232)^{0.63}(4.32)^{0.36}(4.32/1.96)^{0.25} = 269.3\end{aligned}$$

Assuming that $N_L > 16$, the average Nusselt number and heat transfer coefficient for all the tubes in the tube bank become

$$\mathrm{Nu}_{D,N_L} = \mathrm{Nu}_D = 269.3$$

$$h = \frac{Nu_{D,N_L}k}{D} = \frac{269.3(0.631\text{ W/m}\cdot°\text{C})}{0.01\text{ m}} = 16{,}994\text{ W/m}^2\cdot°\text{C}$$

Consider one-row of tubes in the transpose direction (normal to flow), and thus take N_T =1. Then the heat transfer surface area becomes

$$A_s = N_{tube}\pi DL = (1\times N_L)\pi(0.01\text{ m})(4\text{ m}) = 0.1257N_L$$

Then the log mean temperature difference, and the expression for the rate of heat transfer become

$$\Delta T_{\ln} = \frac{(T_s - T_i)-(T_s-T_e)}{\ln[(T_s-T_i)/(T_s-T_e)]} = \frac{(90-15)-(90-65)}{\ln[(90-15)/(90-65)]} = 45.51°\text{C}$$

$$\dot{Q} = hA_s\Delta T_{\ln} = (16{,}994\text{ W/m}^2\cdot°\text{C})(0.1257N_L)(45.51°\text{C}) = 97{,}220N_L$$

The mass flow rate of water through a cross-section corresponding to N_T =1 and the rate of heat transfer are

$$\dot{m} = \rho A_c V = (999.1\text{ kg/m}^3)(4\times0.03\text{ m}^2)(0.8\text{ m/s}) = 95.91\text{ kg/s}$$

$$\dot{Q} = \dot{m}C_p(T_e - T_i) = (95.91\text{ kg/s})(4179\text{ J/kg.C})(65-15)°\text{C} = 2.004\times10^7\text{ W}$$

Substituting this result into the heat transfer expression above we find th e number of tube rows

$$\dot{Q} = hA_s\Delta T_{\ln} \rightarrow 2.004\times10^7\text{ W} = 97{,}220N_L \rightarrow N_L = \mathbf{206}$$

7-70 Air is cooled by an evaporating refrigerator. The refrigeration capacity and the pressure drop across the tube bank are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The surface temperature of the tubes is equal to the temperature of refrigerant.

Properties The exit temperature of air, and thus the mean temperature, is not known. We evaluate the air properties at the assumed mean temperature of -5°C (will be checked later) and 1 atm (Table A-15):

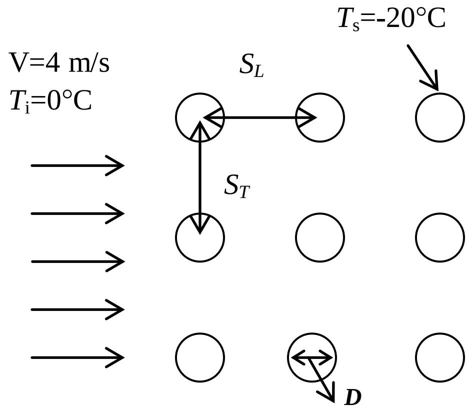
$k = 0.02326$ W/m-K $\qquad \rho = 1.316$ kg/m^3

$C_p = 1.006$ kJ/kg-K $\qquad \Pr = 0.7375$

$\mu = 1.705\times10^{-5}$ kg/m-s $\qquad \Pr_s = \Pr_{@\,T_s} = 0.7408$

Also, the density of air at the inlet temperature of 0°C (for use in the mass flow rate calculation at the inlet) is $\rho_i = 1.292$ kg/m^3.

Analysis It is given that $D = 0.008$ m, $S_L = S_T = 0.015$ m, and V = 4 m/s. Then the maximum velocity and the Reynolds number based on the maximum velocity become



$$\mathrm{V}_{\max} = \frac{S_T}{S_T - D}\mathrm{V} = \frac{0.015}{0.015-0.008}(4\text{ m/s}) = 8.571\text{ m/s}$$

$$\mathrm{Re}_D = \frac{\rho \mathrm{V}_{\max} D}{\mu} = \frac{(1.316\text{ kg/m}^3)(8.571\text{ m/s})(0.008\text{ m})}{1.705\times10^{-5}\text{ kg/m}\cdot\text{s}} = 5294$$

The average Nusselt number is determined using the proper relation from Table 7-2 to be

$$\begin{aligned}\mathrm{Nu}_D &= 0.27\,\mathrm{Re}_D^{0.63}\Pr^{0.36}(\Pr/\Pr_s)^{0.25}\\ &= 0.27(5294)^{0.63}(0.7375)^{0.36}(0.7375/0.7408)^{0.25} = 53.61\end{aligned}$$

Since $N_L > 16$. the average Nusselt number and heat transfer coefficient for all the tubes in the tube bank become

$$\mathrm{Nu}_{D,N_L} = F\mathrm{Nu}_D = 53.61$$

$$h = \frac{Nu_{D,N_L}k}{D} = \frac{53.61(0.02326\text{ W/m}\cdot{}^\circ\text{C})}{0.008\text{ m}} = 155.8\text{ W/m}^2\cdot{}^\circ\text{C}$$

The total number of tubes is $N = N_L \times N_T = 30\times15 = 450$. The heat transfer surface area and the mass flow rate of air (evaluated at the inlet) are

$$A_s = N\pi DL = 300\pi(0.008\text{ m})(0.4\text{ m}) = 4.524\ \text{ m}^2$$

$$\dot{m} = \dot{m}_i = \rho_i \mathrm{V}(N_T S_T L) = (1.292\text{ kg/m}^3)(4\text{ m/s})(15)(0.015\text{ m})(0.4\text{ m}) = 0.4651\text{ kg/s}$$

Then the fluid exit temperature, the log mean temperature difference, and the rate of heat transfer (refrigeration capacity) become

$$T_e = T_s - (T_s - T_i)\exp\left(-\frac{A_s h}{\dot{m}C_p}\right) = -20-(-20-0)\exp\left(-\frac{(4.524\text{ m}^2)(155.8\text{ W/m}^2\cdot{}^\circ\text{C})}{(0.4651\text{ kg/s})(1006\text{ J/kg}\cdot{}^\circ\text{C})}\right) = -15.57^\circ\text{C}$$

$$\Delta T_{\ln} = \frac{(T_s - T_i)-(T_s - T_e)}{\ln[(T_s - T_i)/(T_s - T_e)]} = \frac{(-20-0)-[-20-(-15.57)]}{\ln[(-20-0)/(-20+15.57)]} = 10.33^\circ\text{C}$$

$$\dot{Q} = hA_s\Delta T_{\ln} = (155.8\text{ W/m}^2\cdot{}^\circ\text{C})(4.524\text{ m}^2)(10.33^\circ\text{C}) = \mathbf{7285\ W}$$

For this square in-line tube bank, the friction coefficient corresponding to $\mathrm{Re}_D = 5294$ and $S_L/D = 1.5/0.8 = 1.875$ is, from Fig. 7-27a, $f = 0.27$. Also, $\chi = 1$ for the square arrangements. Then the pressure drop across the tube bank becomes

$$\Delta P = N_L f\chi \frac{\rho V_{\max}^2}{2} = 30(0.27)(1)\frac{(1.316\ \mathrm{kg/m^3})(8.571\ \mathrm{m/s})^2}{2}\left(\frac{1\ \mathrm{N}}{1\ \mathrm{kg\cdot m/s^2}}\right) = \mathbf{391.6\ \ Pa}$$

Discussion The arithmetic mean fluid temperature is $(T_i + T_e)/2 = (0 - 15.6)/2 = -7.8$°C, which is fairly close to the assumed value of -5°C. Therefore, there is no need to repeat calculations.

7-71 Air is cooled by an evaporating refrigerator. The refrigeration capacity and the pressure drop across the tube bank are to be determined.

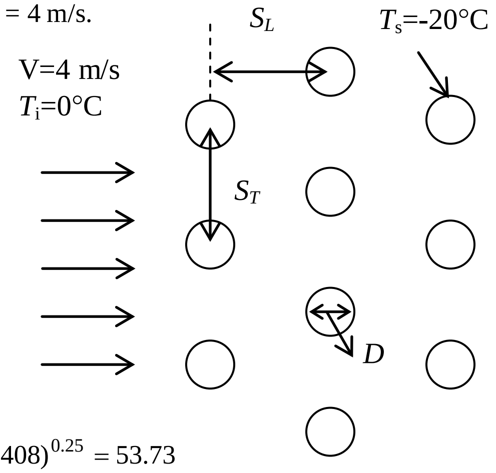
Assumptions **1** Steady operating conditions exist. **2** The surface temperature of the tubes is equal to the temperature of refrigerant.

Properties The exit temperature of air, and thus the mean temperature, is not known. We evaluate the air properties at the assumed mean temperature of -5°C (will be checked later) and 1 atm (Table A-15):

$k = 0.02326$ W/m-K	$\rho = 1.316$ kg/m^3
$C_p = 1.006$ kJ/kg-K	$\mathrm{Pr} = 0.7375$
$\mu = 1.705\times10^{-5}$ kg/m-s	$\mathrm{Pr}_s = \mathrm{Pr}_{@\,Ts} = 0.7408$

Also, the density of air at the inlet temperature of 0°C (for use in the mass flow rate calculation at the inlet) is $\rho_i = 1.292$ kg/m^3.

Analysis It is given that $D = 0.008$ m, $S_L = S_T = 0.015$ m, and V = 4 m/s. Then the maximum velocity and the Reynolds number based on the maximum velocity become



$$\mathrm{V}_{\max} = \frac{S_T}{S_T - D}\mathrm{V} = \frac{0.015}{0.015-0.008}(4\ \mathrm{m/s}) = 8.571\ \mathrm{m/s}$$

$$\mathrm{Re}_D = \frac{\rho \mathrm{V}_{\max} D}{\mu} = \frac{(1.316\ \mathrm{kg/m^3})(8.571\ \mathrm{m/s})(0.008\ \mathrm{m})}{1.705\times10^{-5}\ \mathrm{kg/m\cdot s}} = 5294$$

The average Nusselt number is determined using the proper relation from Table 7-2 to be

$$\begin{aligned}\mathrm{Nu}_D &= 0.35(S_T/S_L)^{0.2}\,\mathrm{Re}_D^{0.6}\,\mathrm{Pr}^{0.36}(\mathrm{Pr}/\mathrm{Pr}_s)^{0.25}\\ &= 0.35(0.015/0.015)^{0.2}(5294)^{0.6}(0.7375)^{0.36}(0.7375/0.7408)^{0.25} = 53.73\end{aligned}$$

Since $N_L > 16$. the average Nusselt number and heat transfer coefficient for all the tubes in the tube bank become

$$\mathrm{Nu}_{D,N_L} = F\mathrm{Nu}_D = 53.73$$

$$h = \frac{Nu_{D,N_L}k}{D} = \frac{53.73(0.02326\ \mathrm{W/m\cdot{}^\circ C})}{0.008\ \mathrm{m}} = 156.2\ \mathrm{W/m^2\cdot{}^\circ C}$$

The total number of tubes is $N = N_L \times N_T = 30\times15 = 450$. The heat transfer surface area and the mass flow rate of air (evaluated at the inlet) are

$$A_s = N\pi DL = 300\pi(0.008\ \mathrm{m})(0.4\ \mathrm{m}) = 4.524\ \ \mathrm{m^2}$$

$$\dot m = \dot m_i = \rho_i \mathrm{V}(N_T S_T L) = (1.292\ \mathrm{kg/m^3})(4\ \mathrm{m/s})(15)(0.015\ \mathrm{m})(0.4\ \mathrm{m}) = 0.4651\ \mathrm{kg/s}$$

Then the fluid exit temperature, the log mean temperature difference, and the rate of heat transfer (refrigeration capacity) become

$$T_e = T_s - (T_s - T_i)\exp\left(-\frac{A_s h}{\dot m C_p}\right) = -20-(-20-0)\exp\left(-\frac{(4.524\ \mathrm{m^2})(156.2\ \mathrm{W/m^2\cdot{}^\circ C})}{(0.4651\ \mathrm{kg/s})(1006\ \mathrm{J/kg\cdot{}^\circ C})}\right) = -15.58^\circ\mathrm{C}$$

$$\Delta T_{\ln} = \frac{(T_s - T_i)-(T_s - T_e)}{\ln[(T_s - T_i)/(T_s - T_e)]} = \frac{(-20-0)-[-20-(-15.58)]}{\ln[(-20-0)/(-20+15.58)]} = 10.32^\circ\mathrm{C}$$

$$\dot Q = hA_s\Delta T_{\ln} = (156.2\ \mathrm{W/m^2\cdot{}^\circ C})(4.524\ \mathrm{m^2})(10.32^\circ\mathrm{C}) = \mathbf{7294\ W}$$

For this staggered arrangement tube bank, the friction coefficient corresponding to $\mathrm{Re}_D = 5294$ and $S_L/D = 1.5/0.8 = 1.875$ is, from Fig. 7-27b, $f = 0.44$. Also, $\chi = 1$ for the square arrangements. Then the pressure drop across the tube bank becomes

$$\Delta P = N_L f\chi \frac{\rho \mathrm{V}_{\max}^2}{2} = 30(0.44)(1)\frac{(1.316\ \mathrm{kg/m^3})(8.571\ \mathrm{m/s})^2}{2}\left(\frac{1\ \mathrm{N}}{1\ \mathrm{kg\cdot m/s^2}}\right) = \mathbf{638.2\ \ Pa}$$

Discussion The arithmetic mean fluid temperature is $(T_i + T_e)/2 = (0\ -15.6)/2 = -7.8°\mathrm{C}$, which is fairly close to the assumed value of -5°C. Therefore, there is no need to repeat calculations.

7-72 Air is heated by hot tubes in a tube bank. The average heat transfer coefficient is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The surface temperature of the tubes is constant.

Properties The exit temperature of air, and thus the mean temperature, is not known. We evaluate the air properties at the assumed mean temperature of 70°C and 1 atm (Table A-15):

$k = 0.02881$ W/m-K

$\rho = 1.028\ \mathrm{kg/m^3}$

$C_p = 1.007$ kJ/kg-K

$\mathrm{Pr} = 0.7177$

$\mu = 2.052\times10^{-5}$ kg/m-s

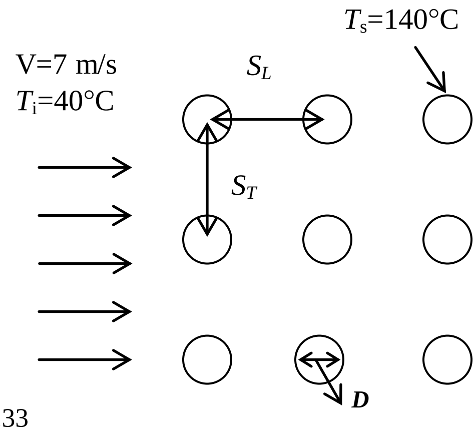
$\mathrm{Pr}_s = \mathrm{Pr}_{@\,Ts} = 0.7041$

Also, the density of air at the inlet temperature of 40°C (for use in the mass flow rate calculation at the inlet) is $\rho_i = 1.127\ \mathrm{kg/m^3}$.

Analysis It is given that $D = 0.02$ m, $S_L = S_T = 0.06$ m, and V = 7 m/s. Then the maximum velocity and the Reynolds number based on the maximum velocity become

$$\mathrm{V}_{\max} = \frac{S_T}{S_T - D}\mathrm{V} = \frac{0.06}{0.06 - 0.02}(7\ \mathrm{m/s}) = 10.50\ \mathrm{m/s}$$

$$\mathrm{Re}_D = \frac{\rho \mathrm{V}_{\max} D}{\mu} = \frac{(1.028\ \mathrm{kg/m^3})(10.50\ \mathrm{m/s})(0.02\ \mathrm{m})}{2.052\times10^{-5}\ \mathrm{kg/m\cdot s}} = 10{,}524$$



The average Nusselt number is determined using the proper relation from Table 7-2 to be

$$\begin{aligned}\mathrm{Nu}_D &= 0.27\,\mathrm{Re}_D^{0.63}\,\mathrm{Pr}^{0.36}(\mathrm{Pr}/\mathrm{Pr}_s)^{0.25}\\ &= 0.27(10{,}524)^{0.63}(0.7177)^{0.36}(0.7177/0.7041)^{0.25} = 82.33\end{aligned}$$

Since $N_L > 16$, the average Nusselt number and heat transfer coefficient for all the tubes in the tube bank become

$$\mathrm{Nu}_{D,N_L} = \mathrm{Nu}_D = 82.33$$

$$h = \frac{Nu_{D,N_L}k}{D} = \frac{82.33(0.02881\ \mathrm{W/m\cdot°C})}{0.02\ \mathrm{m}} = \mathbf{118.6\ W/m^2\cdot°C}$$

Special Topic: Thermal Insulation

7-73C Thermal insulation is a material that is used primarily to provide resistance to heat flow. It differs from other kinds of insulators in that the purpose of an electrical insulator is to halt the flow of electric current, and the purpose of a sound insulator is to slow down the propagation of sound waves.

7-74C In *cold surfaces* such as chilled water lines, refrigerated trucks, and air conditioning ducts, insulation saves energy since the source of "coldness" is *refrigeration* that requires energy input. In this case heat is transferred from the surroundings to the cold surfaces, and the refrigeration unit must now work harder and longer to make up for this heat gain and thus it must consume more electrical energy.

7-75C The *R*-value of insulation is the *thermal resistance* of the insulating material *per unit surface area*. For *flat insulation* the *R*-value is obtained by simply dividing the thickness of the insulation by its thermal conductivity. That is, R-value = L/k. Doubling the thickness L doubles the *R*-value of flat insulation.

7-76C The R-value of an insulation represents the thermal resistance of insulation *per unit surface area* (or per unit length in the case of pipe insulation).

7-77C Superinsulations are obtained by using layers of highly reflective sheets separated by glass fibers in an evacuated space. Radiation between two surfaces is inversely proportional to the number of sheets used and thus heat loss by radiation will be very low by using this highly reflective sheets. Evacuating the space between the layers forms a vacuum which minimize conduction or convection through the air space.

7-78C Yes, hair or any other cover reduces heat loss from the head, and thus serves as insulation for the head. The insulating ability of hair or feathers is most visible in birds and hairy animals.

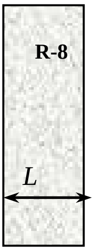
7-79C The primary reasons for insulating are energy conservation, personnel protection and comfort, maintaining process temperature, reducing temperature variation and fluctuations, condensation and corrosion prevention, fire protection, freezing protection, and reducing noise and vibration.

7-80C The *optimum* thickness of insulation is the thickness that corresponds to a minimum combined cost of insulation and heat lost. The cost of insulation increases roughly linearly with thickness while the cost of heat lost decreases exponentially. The total cost, which is the sum of the two, decreases first, reaches a minimum, and then increases. The thickness that corresponds to the minimum total cost is the optimum thickness of insulation, and this is the recommended thickness of insulation to be installed.

7-81 The thickness of flat *R*-8 insulation in SI units is to be determined when the thermal conductivity of the material is known.

Assumptions Thermal properties are constant.

Properties The thermal conductivity of the insulating material is given to be k = 0.04 W/m·°C



Analysis The thickness of flat *R*-8 insulation (in m^2.°C/W) is determined from the definition of *R*-value to be

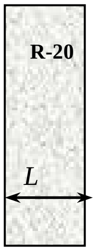
$$R_{\text{value}} = \frac{L}{k} \quad \to \quad L = R_{\text{value}} k = (8\ \text{m}^2.^\circ\text{C / W})(0.04\ \text{W / m.}^\circ\text{C}) = \mathbf{0.32\ m}$$

7-82E The thickness of flat *R*-20 insulation in English units is to be determined when the thermal conductivity of the material is known.

Assumptions Thermal properties are constant.

Properties The thermal conductivity of the insulating material is given to be k = 0.02 Btu/h·ft·°F.

Analysis The thickness of flat *R*-20 insulation (in h·ft^2·°F/Btu) is determined from the definition of *R*-value to be



$$R_{\text{value}} = \frac{L}{k} \to L = R_{\text{value}} k = (20\ \text{h.ft}^2.^\circ\text{F/Btu})(0.02\ \text{Btu/h.ft.}^\circ\text{F}) = \mathbf{0.4\ ft}$$

7-83 A steam pipe is to be covered with enough insulation to reduce the exposed surface temperature to 30°C . The thickness of insulation that needs to be installed is to be determined.

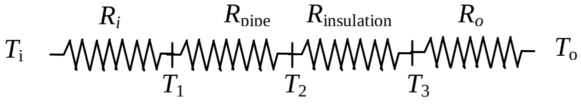
Assumptions **1** Heat transfer is steady since there is no indication of any change with time. **2** Heat transfer is one-dimensional since there is thermal symmetry about the centerline and no variation in the axial direction. **3** Thermal properties are constant. **4** The thermal contact resistance at the interface is negligible.

Properties The thermal conductivities are given to be k = 52 W/m·°C for cast iron pipe and k = 0.038 W/m·°C for fiberglass insulation.

Analysis The thermal resistance network for this problem involves 4 resistances in series. The inner radius of the pipe is r_1 = 2.0 cm and the outer radius of the pipe and thus the inner radius of insulation is r_2 = 2.3 cm. Letting r_3 represent the outer radius of insulation, the areas of the surfaces exposed to convection for a L = 1 m long section of the pipe become

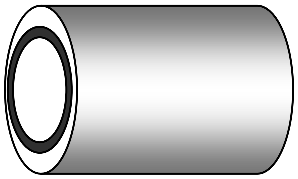
$$A_1 = 2\pi r_1 L = 2\pi(0.02\text{ m})(1\text{ m}) = 0.1257\text{ m}^2$$

$$A_3 = 2\pi r_3 L = 2\pi r_3(1\text{ m}) = 2\pi r_3\text{ m}^2 \quad (r_3\text{ in m})$$



Then the individual thermal resistances are determined to be

$$R_i = R_{\text{conv},1} = \frac{1}{h_i A_1} = \frac{1}{(80\text{ W/m}^2.^\circ\text{C})(0.1257\text{ m}^2)} = 0.9944\ ^\circ\text{C/W}$$



$$R_1 = R_{\text{pipe}} = \frac{\ln(r_2/r_1)}{2\pi k_1 L} = \frac{\ln(0.023/0.02)}{2\pi(52\text{ W/m.}^\circ\text{C})(1\text{ m})} = 0.00043\ ^\circ\text{C/W}$$

$$R_2 = R_{\text{insulation}} = \frac{\ln(r_3/r_2)}{2\pi k_2 L} = \frac{\ln(r_3/0.023)}{2\pi(0.038\text{ W/m.}^\circ\text{C})(1\text{ m})} = 4.188\ln(r_3/0.023)\ ^\circ\text{C/W}$$

$$R_o = R_{\text{conv},2} = \frac{1}{h_o A_3} = \frac{1}{(22\text{ W/m}^2.^\circ\text{C})(2\pi r_3\text{ m}^2)} = \frac{1}{138.2 r_3}\ ^\circ\text{C/W}$$

Noting that all resistances are in series, the total resistance is

$$R_{\text{total}} = R_i + R_1 + R_2 + R_o = 0.09944 + 0.00043 + 4.188\ln(r_3/0.023) + 1/(138.2 r_3)\ ^\circ\text{C/W}$$

Then the steady rate of heat loss from the steam becomes

$$\dot{Q} = \frac{T_i - T_o}{R_{\text{total}}} = \frac{(110-22)^\circ\text{C}}{[0.09944 + 0.00043 + 4.188\ln(r_3/0.023) + 1/(138.2 r_3)]^\circ\text{C/W}}$$

Noting that the outer surface temperature of insulation is specified to be 30°C, the rate of heat loss can also be expressed as

$$\dot{Q} = \frac{T_3 - T_o}{R_o} = \frac{(30-22)^\circ\text{C}}{1/(138.2 r_3)^\circ\text{C/W}} = 1106 r_3$$

Setting the two relations above equal to each other and solving for r_3 gives r_3 = 0.0362 m. Then the minimum thickness of fiberglass insulation required is

$t = r_3 - r_2 = 0.0362 - 0.0230 = 0.0132$ m = **1.32 cm**

Therefore, insulating the pipe with at least 1.32 cm thick fiberglass insulation will ensure that the outer surface temperature of the pipe will be at 30°C or below.

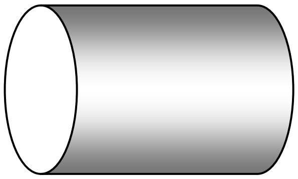
7-85 A cylindrical oven is to be insulated to reduce heat losses. The optimum thickness of insulation and the amount of money saved per year are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat transfer through the insulation is one-dimensional. **3** Thermal conductivities are constant. **4** The thermal contact resistance at the interface is negligible. **5** The surface temperature of the furnace and the heat transfer coefficient remain constant. **6** The surfaces of the cylindrical oven can be treated as plain surfaces since its diameter is greater than 1 m.

Properties The thermal conductivity of insulation is given to be $k = 0.038$ W/m·°C.

Analysis We treat the surfaces of this cylindrical furnace as plain surfaces since its diameter is greater than 1 m, and disregard the curvature effects. The exposed surface area of the furnace is

$$A_o = 2A_{\text{base}} + A_{\text{side}} = 2\pi r^2 + 2\pi rL = 2\pi(1.5\text{ m})^2 + 2\pi(1.5\text{ m})(6\text{ m}) = 70.69\text{ m}^2$$

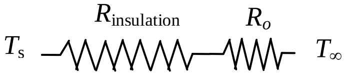


The rate of heat loss from the furnace before the insulation is installed is

$$\dot{Q} = h_o A_o (T_s - T_\infty) = (30\text{ W/m}^2.°\text{C})(70.69\text{ m}^2)(90-27)°\text{C} = 133{,}600\text{ W}$$

Noting that the plant operates 52×80 = 4160 h/yr, the annual heat lost from the furnace is

$$Q = \dot{Q}\Delta t = (133.6\text{ kJ/s})(4160 \times 3600\text{ s/yr}) = 2.001 \times 10^9\text{ kJ/yr}$$



The efficiency of the furnace is given to be 78 percent. Therefore, to generate this much heat, the furnace must consume energy (in the form of natural gas) at a rate of

$$Q_{\text{in}} = Q/\eta_{\text{oven}} = (2.001 \times 10^9\text{ kJ/yr})/0.78 = 2.565 \times 10^9\text{ kJ/yr} = 24{,}314\text{ therms/yr}$$

since 1 therm = 105,500 kJ. Then the annual fuel cost of this furnace before insulation becomes

$$\text{Annual Cost} = \text{Q}_{\text{in}} \times \text{Unit cost} = (24{,}314\text{ therm/yr})(\$0.50/\text{therm}) = \$12{,}157/\text{yr}$$

We expect the surface temperature of the furnace to increase, and the heat transfer coefficient to decrease somewhat when insulation is installed. We assume these two effects to counteract each other. Then the rate of heat loss for 1-cm thick insulation becomes

$$\dot{Q}_{\text{ins}} = \frac{T_s - T_\infty}{R_{\text{total}}} = \frac{T_s - T_\infty}{R_{\text{ins}} + R_{\text{conv}}} = \frac{A_o(T_s - T_\infty)}{\dfrac{t_{\text{ins}}}{k_{\text{ins}}} + \dfrac{1}{h_o}} = \frac{(70.69\text{ m}^2)(90-27)°\text{C}}{\dfrac{0.01\text{ m}}{0.038\text{ W/m.°C}} + \dfrac{1}{30\text{ W/m}^2.°\text{C}}} = 15{,}021\text{ W}$$

Also, the total amount of heat loss from the furnace per year and the amount and cost of energy consumption of the furnace become

$$Q_{\text{ins}} = \dot{Q}_{\text{ins}}\Delta t = (15.021\text{ kJ/s})(4160 \times 3600\text{ s/yr}) = 2.249 \times 10^8\text{ kJ/yr}$$

$$Q_{\text{in,ins}} = Q_{\text{ins}}/\eta_{\text{oven}} = (2.249 \times 10^8\text{ kJ/yr})/0.78 = 2.884 \times 10^8\text{ kJ/yr} = 2734\text{ therms}$$

$$\text{Annual Cost} = \text{Q}_{\text{in,ins}} \times \text{Unit cost} = (2734\text{ therm/yr})(\$0.50/\text{therm}) = \$1367/\text{yr}$$

Cost savings = Energy cost w/o insulation - Energy cost w/insulation = 12,157 - 1367 = $10,790/yr

The unit cost of insulation is given to be $10/m^2 per cm thickness, plus $30/m^2 for labor. Then the total cost of insulation becomes

$$\text{Insulation Cost} = (\text{Unit cost})(\text{Surface area}) = [(\$10/\text{cm})(1\text{ cm}) + \$30/\text{m}^2](70.69\text{ m}^2) = \$2828$$

To determine the thickness of insulation whose cost is equal to annual energy savings, we repeat the calculations above for 2, 3, ... 15 cm thick insulations, and list the results in the table below.

Insulation thickness	Rate of heat loss W	Cost of heat lost $/yr	Cost savings $/yr	Insulation cost $
0 cm	133,600	12,157	0	0
1 cm	15,021	1367	10,790	2828
5 cm	3301	300	11,850	3535
10 cm	1671	152	12,005	9189
11 cm	1521	138	12,019	9897
12 cm	1396	127	12,030	10,604
13 cm	1289	117	12,040	11,310
14 cm	1198	109	12,048	12,017
15 cm	1119	102	12,055	12,724

Therefore, the thickest insulation that will pay for itself in one year is the one whose thickness is **14 cm**.

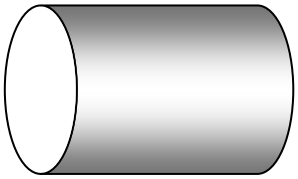
7-86 A cylindrical oven is to be insulated to reduce heat losses. The optimum thickness of insulation and the amount of money saved per year are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat transfer through the insulation is one-dimensional. **3** Thermal conductivities are constant. **4** The thermal contact resistance at the interface is negligible. **5** The surface temperature of the furnace and the heat transfer coefficient remain constant. **6** The surfaces of the cylindrical oven can be treated as plain surfaces since its diameter is greater than 1 m.

Properties The thermal conductivity of insulation is given to be k = 0.038 W/m·°C.

Analysis We treat the surfaces of this cylindrical furnace as plain surfaces since its diameter is greater than 1 m, and disregard the curvature effects. The exposed surface area of the furnace is

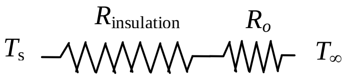
$$A_o = 2A_{\text{base}} + A_{\text{side}} = 2\pi r^2 + 2\pi rL = 2\pi(1.5\text{ m})^2 + 2\pi(1.5\text{ m})(6\text{ m}) = 70.69\text{ m}^2$$



The rate of heat loss from the furnace before the insulation is installed is

$$\dot{Q} = h_o A_o (T_s - T_\infty) = (30\text{ W/m}^2.°\text{C})(70.69\text{ m}^2)(75-27)°\text{C} = 101{,}794\text{ W}$$

Noting that the plant operates 52×80 = 4160 h/yr, the annual heat lost from the furnace is



$$Q = \dot{Q}\Delta t = (101.794\text{ kJ / s})(4160 \times 3600\text{ s / yr}) = 1.524 \times 10^9\text{ kJ / yr}$$

The efficiency of the furnace is given to be 78 percent. Therefore, to generate this much heat, the furnace must consume energy (in the form of natural gas) at a rate of

$$Q_{\text{in}} = Q / \eta_{\text{oven}} = (1.524 \times 10^9\text{ kJ / yr}) / 0.78 = 1.954 \times 10^9\text{ kJ / yr} = 18{,}526\text{ therms / yr}$$

since 1 therm = 105,500 kJ. Then the annual fuel cost of this furnace before insulation becomes

$$\text{Annual Cost} = \text{Q}_{\text{in}} \times \text{Unit cost} = (18{,}526\text{ therm / yr})(\$0.50\text{ / therm}) = \$9{,}263\text{ / yr}$$

We expect the surface temperature of the furnace to increase, and the heat transfer coefficient to decrease somewhat when insulation is installed. We assume these two effects to counteract each other. Then the rate of heat loss for 1-cm thick insulation becomes

$$\dot{Q}_{\text{ins}} = \frac{T_s - T_\infty}{R_{\text{total}}} = \frac{T_s - T_\infty}{R_{\text{ins}} + R_{\text{conv}}} = \frac{A_o(T_s - T_\infty)}{\dfrac{t_{\text{ins}}}{k_{\text{ins}}} + \dfrac{1}{h_o}} = \frac{(70.69\text{ m}^2)(75-27)°\text{C}}{\dfrac{0.01\text{ m}}{0.038\text{ W/m.°C}} + \dfrac{1}{30\text{ W/m}^2.°\text{C}}} = 11{,}445\text{ W}$$

Also, the total amount of heat loss from the furnace per year and the amount and cost of energy consumption of the furnace become

$$Q_{\text{ins}} = \dot{Q}_{\text{ins}}\Delta t = (11.445\text{ kJ / s})(4160 \times 3600\text{ s / yr}) = 1.714 \times 10^8\text{ kJ / yr}$$

$$Q_{\text{in,ins}} = Q_{\text{ins}} / \eta_{\text{oven}} = (1.714 \times 10^8\text{ kJ / yr}) / 0.78 = 2.197 \times 10^8\text{ kJ / yr} = 2082\text{ therms}$$

$$\text{Annual Cost} = Q_{\text{in,ins}} \times \text{Unit cost} = (2082\text{ therm / yr})(\$0.50\text{ / therm}) = \$1041\text{ / yr}$$

Cost savings = Energy cost w/o insulation - Energy cost w/insulation = 9263 - 1041 = \$8222/yr

The unit cost of insulation is given to be \$10/m^2 per cm thickness, plus \$30/m^2 for labor. Then the total cost of insulation becomes

$$\text{Insulation Cost} = (\text{Unit cost})(\text{Surface area}) = [(\$10\text{ / cm})(1\text{ cm}) + \$30\text{ / m}^2](70.69\text{ m}^2) = \$2828$$

To determine the thickness of insulation whose cost is equal to annual energy savings, we repeat the calculations above for 2, 3, ... 15 cm thick insulations, and list the results in the table below.

Insulation Thickness	Rate of heat loss W	Cost of heat lost $/yr	Cost savings $/yr	Insulation cost $
0 cm	101,794	9263	0	0
1 cm	11,445	1041	8222	2828
5 cm	2515	228	9035	3535
9 cm	1413	129	9134	8483
10 cm	1273	116	9147	9189
11 cm	1159	105	9158	9897
12 cm	1064	97	9166	10,604

Therefore, the thickest insulation that will pay for itself in one year is the one whose thickness is **9 cm**. The 10-cm thick insulation will come very close to paying for itself in one year.

7-87E Steam is flowing through an insulated steel pipe, and it is proposed to add another 1-in thick layer of fiberglass insulation on top of the existing one to reduce the heat losses further and to save energy and money. It is to be determined if the new insulation will pay for itself within 2 years.

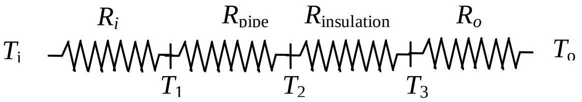
Assumptions **1** Heat transfer is steady since there is no indication of any change with time. **2** Heat transfer is one-dimensional since there is thermal symmetry about the centerline and no variation in the axial direction. **3** Thermal properties are constant. **4** The heat transfer coefficients remain constant. **5** The thermal contact resistance at the interface is negligible.

Properties The thermal conductivities are given to be k = 8.7 Btu/h·ft·°F for steel pipe and k = 0.020 Btu/h·ft·°F for fiberglass insulation.

Analysis The inner radius of the pipe is r_1 = 1.75 in, the outer radius of the pipe is r_2 = 2 in, and the outer radii of the existing and proposed insulation layers are r_3 = 3 in and 4 in, respectively. Considering a unit pipe length of L = 1 ft, the individual thermal resistances are determined to be

$$R_i = R_{\text{conv},1} = \frac{1}{h_i A_1} = \frac{1}{h_i(2\pi r_1 L)} = \frac{1}{(30\text{ Btu/h.ft}^2.^\circ\text{F})[2\pi(1.75/12\text{ ft})(1\text{ ft})]} = 0.0364\text{ h.}^\circ\text{F/Btu}$$

$$R_1 = R_{\text{pipe}} = \frac{\ln(r_2/r_1)}{2\pi k_1 L} = \frac{\ln(2/1.75)}{2\pi(8.7\text{ Btu/h.ft.}^\circ\text{F})(1\text{ ft})} = 0.00244\text{ h.}^\circ\text{F/Btu}$$



Current Case:

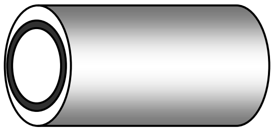
$$R_{\text{insulation}} = \frac{\ln(r_3/r_2)}{2\pi k_{\text{ins}} L} = \frac{\ln(3/2)}{2\pi(0.020\text{ Btu/h.ft.}^\circ\text{F})(1\text{ ft})} = 3.227\text{ h.}^\circ\text{F/Btu}$$

$$R_o = R_{\text{conv},2} = \frac{1}{h_o A_3} = \frac{1}{h_o(2\pi r_3)} = \frac{1}{(5\text{ Btu/h.ft}^2.^\circ\text{F})[2\pi(3/12\text{ ft})(1\text{ ft})]} = 0.1273\text{ h.}^\circ\text{F/Btu}$$

Then the steady rate of heat loss from the steam becomes

$$\dot{Q}_{\text{current}} = \frac{\Delta T}{R_{\text{total}}} = \frac{T_i - T_o}{R_i + R_{\text{pipe}} + R_{\text{ins}} + R_o} = \frac{(400-60)^\circ\text{F}}{(0.0364 + 0.00244 + 3.227 + 0.1273)\text{ h.}^\circ\text{F/Btu}} = 100.2\text{ Btu/h}$$

Proposed Case:



$$R_{\text{insulation}} = \frac{\ln(r_3/r_2)}{2\pi k_{ins} L} = \frac{\ln(4/2)}{2\pi(0.020\text{ Btu/h.ft.}^\circ\text{F})(1\text{ ft})} = 5.516\text{ h.}^\circ\text{F/Btu}$$

$$R_o = R_{\text{conv},2} = \frac{1}{h_o A_3} = \frac{1}{h_o(2\pi r_3)} = \frac{1}{(5\text{ Btu/h.ft}^2.^\circ\text{F})[2\pi(4/12\text{ ft})(1\text{ ft})]} = 0.0955\text{ h.}^\circ\text{F/Btu}$$

Then the steady rate of heat loss from the steam becomes

$$\dot{Q}_{\text{prop}} = \frac{\Delta T}{R_{\text{total}}} = \frac{T_i - T_o}{R_i + R_{\text{pipe}} + R_{\text{ins}} + R_o} = \frac{(400-60)^\circ\text{F}}{(0.0364 + 0.00244 + 5.516 + 0.0955)\text{ h.}^\circ\text{F/Btu}} = 60.2\text{ Btu/h}$$

Therefore, the amount of energy and money saved by the additional insulation per year are

$$\dot{Q}_{\text{saved}} = \dot{Q}_{\text{prop}} - \dot{Q}_{\text{current}} = 100.2 - 60.2 = 40.0\text{ Btu/h}$$

$$Q_{\text{saved}} = \dot{Q}_{\text{saved}}\Delta t = (40.0\text{ Btu/h})(8760\text{ h/yr}) = 350{,}400\text{ Btu/yr}$$

$$\text{Money saved} = Q_{\text{saved}} \times (\text{Unit cost}) = (350{,}400\text{ Btu/yr})(\$0.01/1000\text{ Btu}) = \$3.504/\text{yr}$$

or $7.01 per 2 years, which is barely more than the $7.0 minimum required. But the criteria is satisfied, and the proposed additional insulation is **justified**.

7-88 The plumbing system of a plant involves some section of a plastic pipe exposed to the ambient air. The pipe is to be insulated with adequate fiber glass insulation to prevent freezing of water in the pipe. The thickness of insulation that will protect the water from freezing under worst conditions is to be determined.

Assumptions **1** Heat transfer is transient, but can be treated as steady at average conditions. **2** Heat transfer is one-dimensional since there is thermal symmetry about the centerline and no variation in the axial direction. **3** Thermal properties are constant. **4** The water in the pipe is stationary, and its initial temperature is 15°C. **5** The thermal contact resistance at the interface is negligible. **6** The convection resistance inside the pipe is negligible.

Properties The thermal conductivities are given to be k = 0.16 W/m·°C for plastic pipe and k = 0.035 W/m·°C for fiberglass insulation. The density and specific heat of water are to be ρ = 1000 kg/m^3 and C_p = 4.18 kJ/kg.°C (Table A-15).

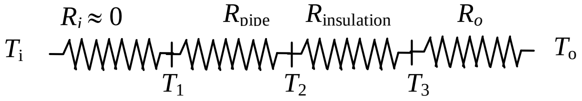
Analysis The inner radius of the pipe is r_1 = 3.0 cm and the outer radius of the pipe and thus the inner radius of insulation is r_2 = 3.3 cm. We let r_3 represent the outer radius of insulation. Considering a 1-m section of the pipe, the amount of heat that must be transferred from the water as it cools from 15 to 0°C is determined to be

$$m = \rho V = \rho(\pi r_1^2 L) = (1000\ \text{kg/m}^3)[\pi(0.03\ \text{m})^2(1\ \text{m})] = 2.827\ \text{kg}$$

$$Q_{\text{total}} = mC_p\Delta T = (2.827\ \text{kg})(4.18\ \text{kJ/kg.°C})(15-0)\text{°C} = 177.3\ \text{kJ}$$

Then the average rate of heat transfer during 60 h becomes

$$\dot{Q}_{\text{ave}} = \frac{Q_{\text{total}}}{\Delta t} = \frac{177{,}300\ \text{J}}{(60\times 3600\ \text{s})} = 0.821\ \text{W}$$

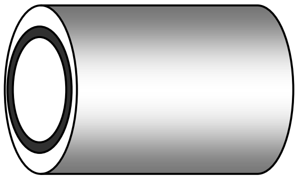


The individual thermal resistances are

$$R_1 = R_{\text{pipe}} = \frac{\ln(r_2/r_1)}{2\pi k_{\text{pipe}}L} = \frac{\ln(0.033/0.03)}{2\pi(0.16\ \text{W/m.°C})(1\ \text{m})} = 0.0948\ \text{°C/W}$$

$$R_{\text{insulation}} = \frac{\ln(r_3/r_2)}{2\pi k_2 L} = \frac{\ln(r_3/0.033)}{2\pi(0.035\ \text{W/m.°C})(1\ \text{m})} = 4.55\ln(r_3/0.033)\ \text{°C/W}$$

$$R_o = R_{\text{conv}} = \frac{1}{h_o A_3} = \frac{1}{(30\ \text{W/m}^2.\text{°C})(2\pi r_3\ \text{m}^2)} = \frac{1}{188.5 r_3}\ \text{°C/W}$$



Then the rate of average heat transfer from the water can be expressed as

$$\dot{Q} = \frac{T_{i,ave} - T_o}{R_{\text{total}}} \quad \rightarrow \quad 0.821\ \text{W} = \frac{[7.5-(-10)]\text{°C}}{[0.0948 + 4.55\ln(r_3/0.033) + 1/(188.5r_3)]\text{°C/W}} \quad \rightarrow \quad r_3 = 3.50\ \text{m}$$

Therefore, the minimum thickness of fiberglass needed to protect the pipe from freezing is

$t = r_3 - r_2 = 3.50 - 0.033 =$ **3.467 m**

which is too large. Installing such a thick insulation is not practical, however, and thus other freeze protection methods should be considered.

7-89 The plumbing system of a plant involves some section of a plastic pipe exposed to the ambient air. The pipe is to be insulated with adequate fiber glass insulation to prevent freezing of water in the pipe. The thickness of insulation that will protect the water from freezing more than 20% under worst conditions is to be determined.

Assumptions **1** Heat transfer is transient, but can be treated as steady at average conditions. **2** Heat transfer is one-dimensional since there is thermal symmetry about the centerline and no variation in the axial direction. **3** Thermal properties are constant. **4** The water in the pipe is stationary, and its initial temperature is 15°C. **5** The thermal contact resistance at the interface is negligible. **6** The convection resistance inside the pipe is negligible.

Properties The thermal conductivities are given to be k = 0.16 W/m·°C for plastic pipe and k = 0.035 W/m·°C for fiberglass insulation. The density and specific heat of water are to be ρ = 1000 kg/m^3 and C_p = 4.18 kJ/kg.°C (Table A-15).

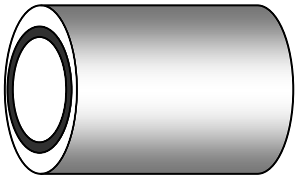
Analysis The inner radius of the pipe is r_1 = 3.0 cm and the outer radius of the pipe and thus the inner radius of insulation is r_2 = 3.3 cm. We let r_3 represent the outer radius of insulation. The latent heat of freezing of water is 33.7 kJ/kg. Considering a 1-m section of the pipe, the amount of heat that must be transferred from the water as it cools from 15 to 0°C is determined to be

$$m = \rho V = \rho(\pi r_1^2 L) = (1000\ \text{kg/m}^3)[\pi(0.03\,\text{m})^2(1\,\text{m})] = 2.827\ \text{kg}$$

$$Q_{\text{total}} = mC_p\Delta T = (2.827\ \text{kg})(4.18\ \text{kJ/kg.°C})(15-0)\text{°C} = 177.3\ \text{kJ}$$

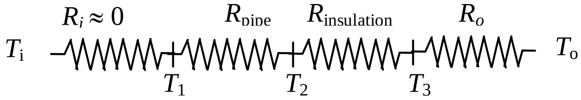
$$Q_{\text{freezing}} = 0.2\times mh_{if} = 0.2\times(2.827\ \text{kg})(333.7\ \text{kJ/kg}) = 188.7\ \text{kJ}$$

$$Q_{\text{total}} = Q_{\text{cooling}} + Q_{\text{freezing}} = 177.3 + 188.7 = 366.0\ \text{kJ}$$



Then the average rate of heat transfer during 60 h becomes

$$\dot{Q}_{\text{ave}} = \frac{Q_{\text{total}}}{\Delta t} = \frac{366{,}000\ \text{J}}{(60\times 3600\ \text{s})} = 1.694\ \text{W}$$



The individual thermal resistances are

$$R_1 = R_{\text{pipe}} = \frac{\ln(r_2/r_1)}{2\pi k_{\text{pipe}}L} = \frac{\ln(0.033/0.03)}{2\pi(0.16\ \text{W/m.°C})(1\ \text{m})} = 0.0948\ \text{°C/W}$$

$$R_{\text{insulation}} = \frac{\ln(r_3/r_2)}{2\pi k_2 L} = \frac{\ln(r_3/0.033)}{2\pi(0.035\ \text{W/m.°C})(1\ \text{m})} = 4.55\ln(r_3/0.033)\ \text{°C/W}$$

$$R_o = R_{\text{conv}} = \frac{1}{h_o A_3} = \frac{1}{(30\ \text{W/m}^2.\text{°C})(2\pi r_3\ \text{m}^2)} = \frac{1}{188.5 r_3}\ \text{°C/W}$$

Then the rate of average heat transfer from the water can be expressed as

$$\dot{Q} = \frac{T_{i,ave} - T_o}{R_{\text{total}}} \rightarrow 1.694\ \text{W} = \frac{[7.5-(-10)]\text{°C}}{[0.0948 + 4.55\ln(r_3/0.033) + 1/(188.5r_3)]\text{°C/W}} \rightarrow r_3 = 0.312\ \text{m}$$

Therefore, the minimum thickness of fiberglass needed to protect the pipe from freezing is

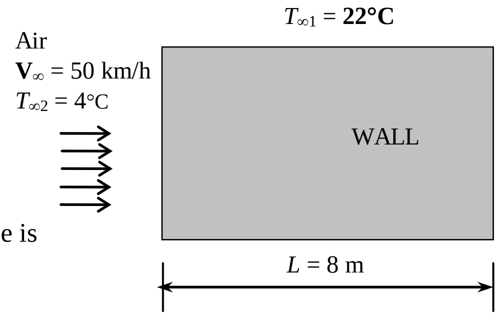
$t = r_3 - r_2$ = 0.312 - 0.033 = **0.279 m**

which is too large. Installing such a thick insulation is not practical, however, and thus other freeze protection methods should be considered.

Review Problems

7-90 Wind is blowing parallel to the walls of a house. The rate of heat loss from the wall is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\text{Re}_{cr} = 5\times10^5$. **3** Radiation effects are negligible. **4** Air is an ideal gas with constant properties. **5** The pressure of air is 1 atm.



Properties Assuming a film temperature of T_f = 10°C for the outdoors, the properties of air are evaluated to be (Table A-15)

$$k = 0.02439 \text{ W/m.°C}$$
$$\upsilon = 1.426\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7336$$

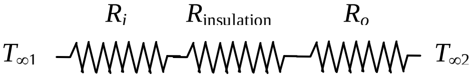
Analysis Air flows along 8-m side. The Reynolds number in this case is

$$\text{Re}_L = \frac{V_\infty L}{\upsilon} = \frac{[(50\times1000/3600)\text{ m/s}](8\text{ m})}{1.426\times10^{-5}\text{ m}^2\text{/s}} = 7.792\times10^6$$

which is greater than the critical Reynolds number. Thus we have combined laminar and turbulent flow. Using the proper relation for Nusselt number, heat transfer coefficient is determined to be

$$Nu = \frac{h_0 L}{k} = (0.037\,\text{Re}_L^{\,0.8} - 871)\,\text{Pr}^{1/3} = \left[0.037(7.792\times10^6)^{0.8} - 871\right](0.7336)^{1/3} = 10{,}096$$

$$h_o = \frac{k}{L}Nu = \frac{0.02439\text{ W/m.°C}}{8\text{ m}}(10{,}096) = 30.78\text{ W/m}^2\text{.°C}$$



The thermal resistances are

$$A_s = wL = (3\text{ m})(8\text{ m}) = 24\text{ m}^2$$

$$R_i = \frac{1}{h_i A_s} = \frac{1}{(8\text{ W/m}^2\text{.°C})(24\text{ m}^2)} = 0.0052\text{ °C/W}$$

$$R_{insulation} = \frac{(R-3.38)_{value}}{A_s} = \frac{3.38\text{ m}^2\text{.°C/W}}{24\text{ m}^2} = 0.1408\text{ °C/W}$$

$$R_o = \frac{1}{h_o A_s} = \frac{1}{(30.78\text{ W/m}^2\text{.°C})(24\text{ m}^2)} = 0.0014\text{ °C/W}$$

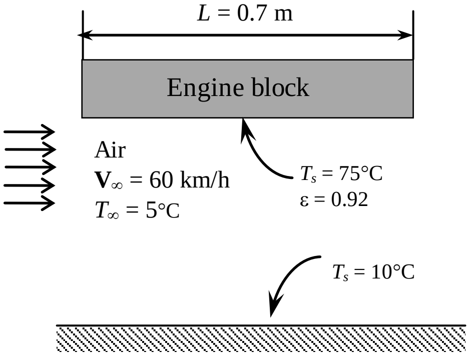
Then the total thermal resistance and the heat transfer rate through the wall are determined from

$$R_{total} = R_i + R_{insulation} + R_o = 0.0052 + 0.1408 + 0.0014 = 0.1474\text{ °C/W}$$

$$\dot{Q} = \frac{T_{\infty1} - T_{\infty2}}{R_{total}} = \frac{(22-4)\text{°C}}{0.1474\text{ °C/W}} = \mathbf{122.1\ W}$$

7-91 A car travels at a velocity of 60 km/h. The rate of heat transfer from the bottom surface of the hot automotive engine block is to be determined for two cases.

Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\text{Re}_{cr} = 5\times10^5$. **3** Air is an ideal gas with constant properties. **4** The pressure of air is 1 atm. **5** The flow is turbulent over the entire surface because of the constant agitation of the engine block. **6** The bottom surface of the engine is a flat surface.



Properties The properties of air at 1 atm and the film temperature of $(T_s + T_\infty)/2 = (75+5)/2 = 40$°C are (Table A-15)

$$k = 0.02662 \text{ W/m.°C}$$
$$\upsilon = 1.702\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7255$$

Analysis The Reynolds number is

$$\text{Re}_L = \frac{V_\infty L}{\upsilon} = \frac{[(60\times1000/3600)\text{ m/s}](0.7\text{ m})}{1.702\times10^{-5}\text{ m}^2\text{/s}} = 6.855\times10^5$$

which is less than the critical Reynolds number. But we will assume turbulent flow because of the constant agitation of the engine block.

$$Nu = \frac{hL}{k} = 0.037\,\text{Re}_L^{\,0.8}\,\text{Pr}^{1/3} = 0.037(6.855\times10^5)^{0.8}(0.7255)^{1/3} = 1551$$

$$h = \frac{k}{L}Nu = \frac{0.02662\text{ W/m.°C}}{0.7\text{ m}}(1551) = 58.97\text{ W/m}^2\text{.°C}$$

$$\dot{Q}_{conv} = hA_s(T_\infty - T_s) = (58.97\text{ W/m}^2\text{.°C})[(0.6\text{ m})(0.7\text{ m})](75-5)\text{°C} = 1734\text{ W}$$

The heat loss by radiation is then determined from Stefan-Boltzman law to be

$$\begin{aligned}\dot{Q}_{rad} &= \varepsilon A_s\sigma(T_s^{\,4} - T_{surr}^{\,4}) \\ &= (0.92)(0.6\text{ m})(0.7\text{ m})(5.67\times10^{-8}\text{ W/m}^2\text{.K}^4)\left[(75+273\text{ K})^4 - (10+273\text{ K})^4\right] = 181\text{ W}\end{aligned}$$

Then the total rate of heat loss from the bottom surface of the engine block becomes

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad} = 1734 + 181 = \mathbf{1915\ W}$$

The gunk will introduce an additional resistance to heat dissipation from the engine. The total heat transfer rate in this case can be calculated from

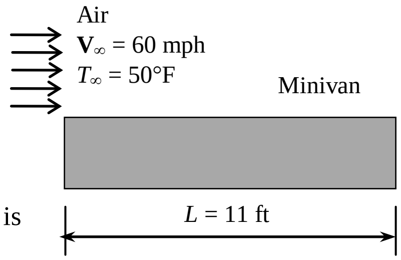
$$\dot{Q} = \frac{T_\infty - T_s}{\dfrac{1}{hA_s} + \dfrac{L}{kA_s}} = \frac{(75-5)\text{°C}}{\dfrac{1}{(58.97\text{ W/m}^2\text{.°C})[(0.6\text{ m})(0.7\text{ m})]} + \dfrac{(0.002\text{ m})}{(3\text{ W/m.°C})(0.6\text{ m}\times0.7\text{ m})}} = 1668\text{ W}$$

The decrease in the heat transfer rate is

1734-1668 = **66 W**

7-92E A minivan is traveling at 60 mph. The rate of heat transfer to the van is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\mathrm{Re}_{cr} = 5\times10^5$. **3** Radiation effects are negligible. **4** Air flow is turbulent because of the intense vibrations involved. **5** Air is an ideal gas with constant properties. **5** The pressure of air is 1 atm.



Properties Assuming a film temperature of T_f = 80°F, the properties of air are evaluated to be (Table A-15E)

$$k = 0.01481\ \text{Btu/h.ft.°F}$$

$$\upsilon = 0.1697\times10^{-3}\ \text{ft}^2\text{/s}$$

$$\mathrm{Pr} = 0.7290$$

Analysis Air flows along 11 ft long side. The Reynolds number in this case is

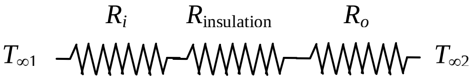
$$\mathrm{Re}_L = \frac{V_\infty L}{\upsilon} = \frac{[(60\times5280/3600)\ \text{ft/s}](11\ \text{ft})}{0.1697\times10^{-3}\ \text{ft}^2\text{/s}} = 5.704\times10^6$$

which is greater than the critical Reynolds number. The air flow is assumed to be entirely turbulent because of the intense vibrations involved. Then the Nusselt number and the heat transfer coefficient are determined to be

$$Nu = \frac{h_o L}{k} = 0.037\,\mathrm{Re}_L^{0.8}\,\mathrm{Pr}^{1/3} = 0.037(5.704\times10^6)^{0.8}(0.7290)^{1/3} = 8461$$

$$h_o = \frac{k}{L}Nu = \frac{0.01481\ \text{Btu/h.ft.°F}}{11\ \text{ft}}(8461) = 11.39\ \text{Btu/h.ft}^2\text{.°F}$$

The thermal resistances are



$$A_s = 2[(3.2\ \text{ft})(6\ \text{ft}) + (3.2\ \text{ft})(11\ \text{ft}) + (6\ \text{ft})(11\ \text{ft})] = 240.8\ \text{ft}^2$$

$$R_i = \frac{1}{h_i A_s} = \frac{1}{(1.2\ \text{Btu/h.ft}^2\text{.°F})(240.8\ \text{ft}^2)} = 0.0035\ \text{h.°F/Btu}$$

$$R_{insulation} = \frac{(R-3)_{value}}{A_s} = \frac{3\ \text{h.ft}^2\text{.°F/Btu}}{(240.8\ \text{ft}^2)} = 0.0125\ \text{h.°F/Btu}$$

$$R_o = \frac{1}{h_o A_s} = \frac{1}{(11.39\ \text{Btu/h.ft}^2\text{.°F})(240.8\ \text{ft}^2)} = 0.0004\ \text{h.°F/Btu}$$

Then the total thermal resistance and the heat transfer rate into the minivan are determined to be

$$R_{total} = R_i + R_{insulation} + R_o = 0.0035 + 0.0125 + 0.0004 = 0.0164\ \text{h.°F/Btu}$$

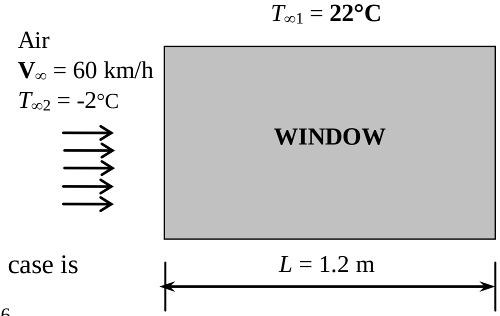
$$\dot{Q} = \frac{T_{\infty1} - T_{\infty2}}{R_{total}} = \frac{(90-70)\text{°F}}{0.0164\ \text{h.°F/Btu}} = \mathbf{1220\ Btu/h}$$

7-93 Wind is blowing parallel to the walls of a house with windows. The rate of heat loss through the window is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\text{Re}_{cr} = 5\times10^5$. **3** Radiation effects are negligible. **4** Air flow is turbulent because of the intense vibrations involved. **5** The minivan is modeled as a rectangular box. **6** Air is an ideal gas with constant properties. **6** The pressure of air is 1 atm.

Properties Assuming a film temperature of 5°C, the properties of air at 1 atm and this temperature are evaluated to be (Table A-15)

$$k = 0.02401\ \text{W/m.°C}$$
$$\upsilon = 1.382\times10^{-5}\ \text{m}^2\text{/s}$$
$$\Pr = 0.7350$$



Analysis Air flows along 1.2 m side. The Reynolds number in this case is

$$\text{Re}_L = \frac{V_\infty L}{\upsilon} = \frac{[(60\times1000/3600)\ \text{m/s}](1.2\ \text{m})}{1.382\times10^{-5}\ \text{m}^2\text{/s}} = 1.447\times10^6$$

which is greater than the critical Reynolds number. Thus we have combined laminar and turbulent flow. Using the proper relation for Nusselt number, heat transfer coefficient is determined to be

$$Nu = \frac{hL}{k} = (0.037\,\text{Re}_L^{\,0.8} - 871)\Pr^{1/3} = [0.037(1.447\times10^6)^{0.8} - 871](0.7350)^{1/3} = 2046$$

$$h = \frac{k}{L}Nu = \frac{0.02401\ \text{W/m.°C}}{1.2\ \text{m}}(2046) = 40.93\ \text{W/m}^2\text{.°C}$$

The thermal resistances are

$$A_s = 3(1.2\ \text{m})(1.5\ \text{m}) = 5.4\ \text{m}^2$$

$$R_{conv,i} = \frac{1}{h_i A_s} = \frac{1}{(8\ \text{W/m}^2\text{.°C})(5.4\ \text{m}^2)} = 0.0231\ \text{°C/W}$$

$$R_{cond} = \frac{L}{kA_s} = \frac{0.005\ \text{m}}{(0.78\ \text{W/m.°C})(5.4\ \text{m}^2)} = 0.0012\ \text{°C/W}$$

$$R_{conv,o} = \frac{1}{h_o A_s} = \frac{1}{(40.93\ \text{W/m}^2\text{.°C})(5.4\ \text{m}^2)} = 0.0045\ \text{°C/W}$$

Then the total thermal resistance and the heat transfer rate through the 3 windows become

$$R_{total} = R_{conv,i} + R_{cond} + R_{conv,o} = 0.0231 + 0.0012 + 0.0045 = 0.0288\ \text{°C/W}$$

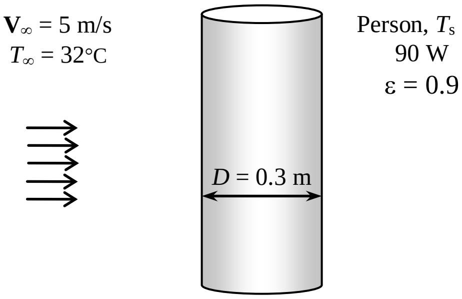
$$\dot{Q} = \frac{T_{\infty1} - T_{\infty2}}{R_{total}} = \frac{[22-(-2)]\text{°C}}{0.0288\ \text{°C/W}} = \mathbf{833.3\ W}$$

7-94 A fan is blowing air over the entire body of a person. The average temperature of the outer surface of the person is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The pressure of air is 1 atm. **4** The average human body can be treated as a 30-cm-diameter cylinder with an exposed surface area of 1.7 m^2.

Properties We assume the film temperature to be 35°C. The properties of air at 1 atm and this temperature are (Table A-15)

$$k = 0.02625 \text{ W/m.°C}$$
$$\upsilon = 1.655 \times 10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7268$$



Analysis The Reynolds number is

$$\text{Re} = \frac{V_\infty D}{\upsilon} = \frac{(5 \text{ m/s})(0.3 \text{ m})}{1.655 \times 10^{-5} \text{ m}^2\text{/s}} = 9.063 \times 10^4$$

The proper relation for Nusselt number corresponding to this Reynolds number is

$$Nu = \frac{hD}{k} = 0.3 + \frac{0.62 \,\text{Re}^{0.5}\,\text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}}\left[1 + \left(\frac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(9.063 \times 10^4)^{0.5}(0.7268)^{1/3}}{\left[1 + (0.4/0.7268)^{2/3}\right]^{1/4}}\left[1 + \left(\frac{9.063 \times 10^4}{282{,}000}\right)^{5/8}\right]^{4/5} = 203.6$$

Then

$$h = \frac{k}{D}Nu = \frac{0.02655 \text{ W/m.°C}}{0.3 \text{ m}}(203.6) = 18.02 \text{ W/m}^2\text{.°C}$$

Considering that there is heat generation in that person's body at a rate of 90 W and body gains heat by radiation from the surrounding surfaces, an energy balance can be written as

$$\dot{Q}_{generated} + \dot{Q}_{radiation} = \dot{Q}_{convection}$$

Substituting values with proper units and then application of trial & error method yields the average temperature of the outer surface of the person.

$$90 \text{ W} + \varepsilon A_s \sigma (T_{surr}{}^4 - T_s{}^4) = hA_s(T_s - T_\infty)$$

$$90 + (0.9)(1.7)(5.67 \times 10^{-8})[(40 + 273)^4 - T_s{}^4] = (18.02)(1.7)[T_s - (32 + 273)]$$

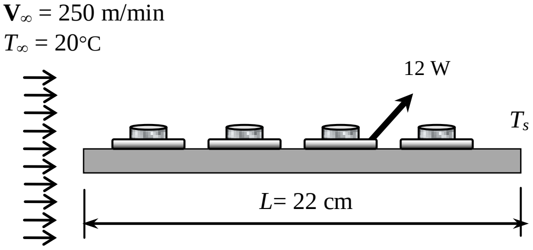
$$T_s = \mathbf{309.2 \text{ K} = 36.2°C}$$

7-95 The heat generated by four transistors mounted on a thin vertical plate is dissipated by air blown over the plate on both surfaces. The temperature of the aluminum plate is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\text{Re}_{cr} = 5\times10^5$. **3** Radiation effects are negligible. **4** The entire plate is nearly isothermal. **5** The exposed surface area of the transistor is taken to be equal to its base area. **6** Air is an ideal gas with constant properties. **7** The pressure of air is 1 atm.

Properties Assuming a film temperature of 40°C, the properties of air are evaluated to be (Table A-15)

$$k = 0.02662 \text{ W/m.°C}$$
$$\upsilon = 1.702\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7255$$



Analysis The Reynolds number in this case is

$$\text{Re}_L = \frac{V_\infty L}{\upsilon} = \frac{[(250/60)\text{ m/s}](0.22\text{ m})}{1.702\times10^{-5}\text{ m}^2\text{/s}} = 5.386\times10^4$$

which is smaller than the critical Reynolds number. Thus we have laminar flow. Using the proper relation for Nusselt number, heat transfer coefficient is determined to be

$$Nu = \frac{hL}{k} = 0.664\,\text{Re}_L^{\;0.5}\,\text{Pr}^{1/3} = 0.664(5.386\times10^4)^{0.5}(0.7255)^{1/3} = 138.5$$

$$h = \frac{k}{L}Nu = \frac{0.02662\text{ W/m.°C}}{0.22\text{ m}}(138.5) = 16.75\text{ W/m}^2\text{.°C}$$

The temperature of aluminum plate then becomes

$$\dot{Q} = hA_s(T_s - T_\infty) \longrightarrow T_s = T_\infty + \frac{\dot{Q}}{hA_s} = 20°\text{C} + \frac{(4\times12)\text{ W}}{(16.75\text{ W/m}^2\text{.°C})[2(0.22\text{ m})^2]} = \mathbf{50.0°C}$$

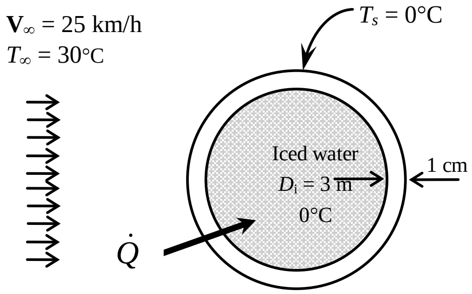
Discussion In reality, the heat transfer coefficient will be higher since the transistors will cause turbulence in the air.

7-96 A spherical tank used to store iced water is subjected to winds. The rate of heat transfer to the iced water and the amount of ice that melts during a 24-h period are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Thermal resistance of the tank is negligible. **3** Radiation effects are negligible. **4** Air is an ideal gas with constant properties. **5** The pressure of air is 1 atm.

Properties The properties of air at 1 atm pressure and the free stream temperature of 30°C are (Table A-15)

$$k = 0.02588 \text{ W/m.°C}$$
$$\upsilon = 1.608\times10^{-5} \text{ m}^2\text{/s}$$
$$\mu_\infty = 1.872\times10^{-5} \text{ kg/m.s}$$
$$\mu_{s,@\,0°\text{C}} = 1.729\times10^{-5} \text{ kg/m.s}$$
$$\text{Pr} = 0.7282$$



Analysis (*a*) The Reynolds number is

$$\text{Re} = \frac{V_\infty D}{\upsilon} = \frac{[(25\times1000/3600)\text{ m/s}](3.02\text{ m})}{1.608\times10^{-5}\text{ m}^2\text{/s}} = 1.304\times10^6$$

The Nusselt number corresponding to this Reynolds number is determined from

$$Nu = \frac{hD}{k} = 2 + \left[0.4\,\text{Re}^{0.5} + 0.06\,\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2 + \left[0.4(1.304\times10^6)^{0.5} + 0.06(1.304\times10^6)^{2/3}\right](0.7282)^{0.4}\left(\frac{1.872\times10^{-5}}{1.729\times10^{-5}}\right)^{1/4} = 1056$$

and $$h = \frac{k}{D}Nu = \frac{0.02588\text{ W/m.°C}}{3.02\text{ m}}(1056) = 9.05\text{ W/m}^2\text{.°C}$$

The rate of heat transfer to the iced water is

$$\dot{Q} = hA_s(T_s - T_\infty) = h(\pi D^2)(T_s - T_\infty) = (9.05\text{ W/m}^2\text{.°C})[\pi(3.02\text{ m})^2](30-0)\text{°C} = \mathbf{7779\ W}$$

(*b*) The amount of heat transfer during a 24-hour period is

$$Q = \dot{Q}\Delta t = (7.779\text{ kJ/s})(24\times3600\text{ s}) = 672{,}079\text{ kJ}$$

Then the amount of ice that melts during this period becomes

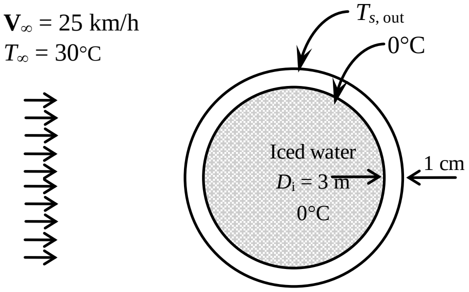
$$Q = mh_{if} \longrightarrow m = \frac{Q}{h_{if}} = \frac{672{,}079\text{ kJ}}{333.7\text{ kJ/kg}} = \mathbf{2014\ kg}$$

7-97 A spherical tank used to store iced water is subjected to winds. The rate of heat transfer to the iced water and the amount of ice that melts during a 24-h period are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **7** The pressure of air is 1 atm.

Properties The properties of air at 1 atm pressure and the free stream temperature of 30°C are (Table A-15)

$k = 0.02588\ \text{W/m.°C}$	$\mu_{s,@\,0°\text{C}} = 1.729\times10^{-5}\ \text{kg/m.s}$
$\upsilon = 1.608\times10^{-5}\ \text{m}^2\text{/s}$	$\text{Pr} = 0.7282$
$\mu_\infty = 1.872\times10^{-5}\ \text{kg/m.s}$	



Analysis (*a*) The Reynolds number is

$$\text{Re} = \frac{V_\infty D}{\upsilon} = \frac{[(25\times1000/3600)\ \text{m/s}](3.02\ \text{m})}{1.608\times10^{-5}\ \text{m}^2\text{/s}} = 1.304\times10^6$$

The Nusselt number corresponding to this Reynolds number is determined from

$$Nu = \frac{hD}{k} = 2 + \left[0.4\,\text{Re}^{0.5} + 0.06\,\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2 + \left[0.4(1.304\times10^6)^{0.5} + 0.06(1.304\times10^6)^{2/3}\right](0.7282)^{0.4}\left(\frac{1.872\times10^{-5}}{1.729\times10^{-5}}\right)^{1/4} = 1056$$

and $$h = \frac{k}{D}Nu = \frac{0.02588\ \text{W/m.°C}}{3.02\ \text{m}}(1056) = 9.05\ \text{W/m}^2\text{.°C}$$

In steady operation, heat transfer through the tank by conduction is equal to the heat transfer from the outer surface of the tank by convection and radiation. Therefore,

$$\dot{Q} = \dot{Q}_{\text{through tank}} = \dot{Q}_{\text{from tank, conv+rad}}$$

$$\dot{Q} = \frac{T_{s,out} - T_{s,in}}{R_{sphere}} = h_o A_o (T_{surr} - T_{s,out}) + \varepsilon A_o \sigma (T_{surr}{}^4 - T_{s,out}{}^4)$$

where $$R_{sphere} = \frac{r_2 - r_1}{4\pi k r_1 r_2} = \frac{(1.51 - 1.50)\ \text{m}}{4\pi(15\ \text{W/m.°C})(1.51\ \text{m})(1.50\ \text{m})} = 2.342\times10^{-5}\ \text{°C/W}$$

$$A_o = \pi D^2 = \pi(3.02\ \text{m})^2 = 28.65\ \text{m}^2$$

Substituting,

$$\dot{Q} = \frac{T_{s,out} - 0°\text{C}}{2.34\times10^{-5}\ \text{°C/W}} = (9.05\ \text{W/m}^2\text{.°C})(28.65\ \text{m}^2)(30 - T_{s,out})°\text{C}$$
$$+ (0.9)(28.65\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\text{.K}^4)[(15 + 273\ \text{K})^4 - (T_{s,out} + 273\ \text{K})^4]$$

whose solution is

$$T_s = 0.23°\text{C} \ \text{ and } \ \dot{Q} = 9630\ \text{W} = \mathbf{9.63\ kW}$$

(*b*) The amount of heat transfer during a 24-hour period is

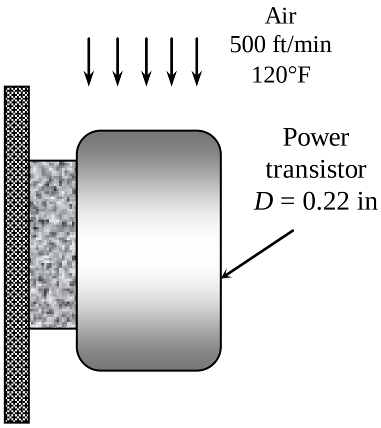
$$Q = \dot{Q}\Delta t = (9.63\ \text{kJ/s})(24\times3600\ \text{s}) = 832{,}032\ \text{kJ}$$

Then the amount of ice that melts during this period becomes

$$Q = mh_{if} \longrightarrow m = \frac{Q}{h_{if}} = \frac{832{,}032\ \text{kJ}}{333.7\ \text{kJ/kg}} = \mathbf{2493\ kg}$$

7-98E A cylindrical transistor mounted on a circuit board is cooled by air flowing over it. The maximum power rating of the transistor is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties. **4** The pressure of air is 1 atm.



Properties The properties of air at 1 atm and the film temperature of $T_f = (180+120)/2 = 150°\text{F}$ are (Table A-15)

$$k = 0.01646\ \text{Btu/h.ft.°F}$$

$$\upsilon = 0.210\times10^{-3}\ \text{ft}^2/\text{s}$$

$$\text{Pr} = 0.7188$$

Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{(500/60\ \text{ft/s})(0.22/12\ \text{ft})}{0.210\times10^{-3}\ \text{ft}^2/\text{s}} = 727.5$$

The Nusselt number corresponding to this Reynolds number is

$$Nu = \frac{hD}{k} = 0.3 + \frac{0.62\,\text{Re}^{0.5}\,\text{Pr}^{1/3}}{\left[1+(0.4/\text{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(727.5)^{0.5}(0.7188)^{1/3}}{\left[1+(0.4/0.7188)^{2/3}\right]^{1/4}}\left[1+\left(\frac{727.5}{282{,}000}\right)^{5/8}\right]^{4/5} = 13.72$$

and $$h = \frac{k}{D}Nu = \frac{0.01646\ \text{Btu/h.ft.°F}}{(0.22/12\ \text{ft})}(13.72) = 12.32\ \text{Btu/h.ft}^2.\text{°F}$$

Then the amount of power this transistor can dissipate safely becomes

$$\dot{Q} = hA_s(T_s - T_\infty) = h(\pi DL)(T_s - T_\infty)$$

$$= (12.32\ \text{Btu/h.ft}^2.\text{°F})\left[\pi(0.22/12\ \text{ft})(0.25/12\ \text{ft})\right](180-120)\text{°C}$$

$$= \mathbf{0.887\ Btu/h = 0.26\ W} \quad (1\,\text{W} = 3.412\ \text{Btu/h})$$

7-99 Wind is blowing over the roof of a house. The rate of heat transfer through the roof and the cost of this heat loss for 14-h period are to be determined.

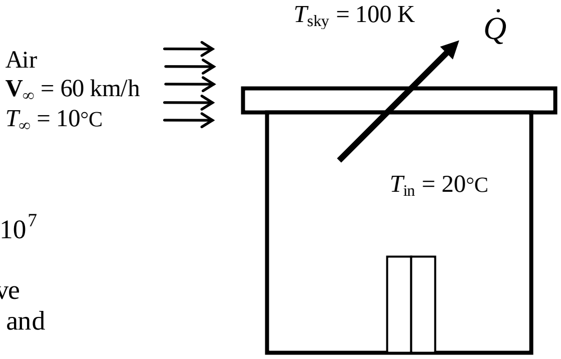
Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\mathrm{Re}_{cr} = 5\times10^5$. **3** Air is an ideal gas with constant properties. **4** The pressure of air is 1 atm.

Properties Assuming a film temperature of 10°C, the properties of air are (Table A-15)

$$k = 0.02439\ \mathrm{W/m.°C}$$

$$\upsilon = 1.426\times10^{-5}\ \mathrm{m^2/s}$$

$$\mathrm{Pr} = 0.7336$$



Analysis The Reynolds number is

$$\mathrm{Re}_L = \frac{V_\infty L}{\upsilon} = \frac{[(60\times1000/3600)\ \mathrm{m/s}](20\ \mathrm{m})}{1.426\times10^{-5}\ \mathrm{m^2/s}} = 2.338\times10^7$$

which is greater than the critical Reynolds number. Thus we have combined laminar and turbulent flow. Then the Nusselt number and the heat transfer coefficient are determined to be

$$Nu = \frac{hL}{k} = (0.037\,\mathrm{Re}_L^{\,0.8} - 871)\,\mathrm{Pr}^{1/3} = [0.037(2.338\times10^7)^{0.8} - 871](0.7336)^{1/3} = 2.542\times10^4$$

$$h = \frac{k}{L}Nu = \frac{0.02439\ \mathrm{W/m.°C}}{20\ \mathrm{m}}(2.542\times10^4) = 31.0\ \mathrm{W/m^2.°C}$$

In steady operation, heat transfer from the room to the roof (by convection and radiation) must be equal to the heat transfer from the roof to the surroundings (by convection and radiation), which must be equal to the heat transfer through the roof by conduction. That is,

$$\dot{Q} = \dot{Q}_{\text{room to roof, conv+rad}} = \dot{Q}_{\text{roof, cond}} = \dot{Q}_{\text{roof to surroundings, conv+rad}}$$

Taking the inner and outer surface temperatures of the roof to be $T_{s,in}$ and $T_{s,out}$, respectively, the quantities above can be expressed as

$$\begin{aligned}\dot{Q}_{\text{room to roof, conv+rad}} &= h_i A_s (T_{room} - T_{s,in}) + \varepsilon A_s \sigma (T_{room}^{\ 4} - T_{s,in}^{\ 4}) = (5\ \mathrm{W/m^2.°C})(300\ \mathrm{m^2})(20 - T_{s,in})\mathrm{°C} \\ &\quad + (0.9)(300\ \mathrm{m^2})(5.67\times10^{-8}\ \mathrm{W/m^2.K^4})\left[(20+273\ \mathrm{K})^4 - (T_{s,in}+273\ \mathrm{K})^4\right]\end{aligned}$$

$$\dot{Q}_{\text{roof, cond}} = kA_s\frac{T_{s,in} - T_{s,out}}{L} = (2\ \mathrm{W/m.°C})(300\ \mathrm{m^2})\frac{T_{s,in} - T_{s,out}}{0.15\ \mathrm{m}}$$

$$\begin{aligned}\dot{Q}_{\text{roof to surr, conv+rad}} &= h_o A_s (T_{s,out} - T_{surr}) + \varepsilon A_s \sigma (T_{s,out}^{\ 4} - T_{surr}^{\ 4}) = (31.0\ \mathrm{W/m^2.°C})(300\ \mathrm{m^2})(T_{s,out} - 10)\mathrm{°C} \\ &\quad + (0.9)(300\ \mathrm{m^2})(5.67\times10^{-8}\ \mathrm{W/m^2.K^4})\left[(T_{s,out}+273\ \mathrm{K})^4 - (100\ \mathrm{K})^4\right]\end{aligned}$$

Solving the equations above simultaneously gives

$$\dot{Q} = 28{,}025\ \mathrm{W} = \mathbf{28.03\ kW}, \qquad T_{s,in} = 10.6\mathrm{°C},\ \text{and}\ T_{s,out} = 3.5\mathrm{°C}$$

The total amount of natural gas consumption during a 14-hour period is

$$Q_{gas} = \frac{Q_{total}}{0.85} = \frac{\dot{Q}\Delta t}{0.85} = \frac{(28.03\ \mathrm{kJ/s})(14\times3600\ \mathrm{s})}{0.85}\left(\frac{1\ \mathrm{therm}}{105{,}500\ \mathrm{kJ}}\right) = 15.75\ \mathrm{therms}$$

Finally, the money lost through the roof during that period is

$$\text{Money lost} = (15.75\ \text{therms})(\$0.60/\text{therm}) = \mathbf{\$9.45}$$

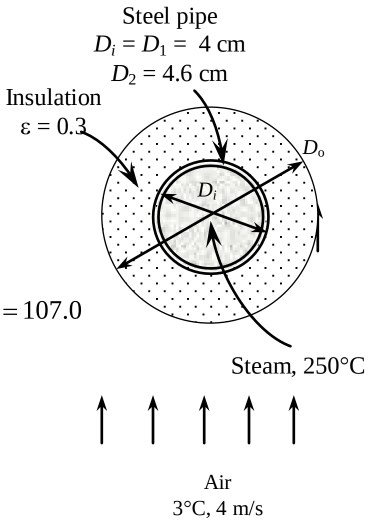
7-100 Steam is flowing in a stainless steel pipe while air is flowing across the pipe. The rate of heat loss from the steam per unit length of the pipe is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The pressure of air is 1 atm.

Properties Assuming a film temperature of 10°C, the properties of air are (Table A-15)

$$k = 0.02439 \text{ W/m.°C}, \qquad \upsilon = 1.426\times10^{-5} \text{ m}^2\text{/s}, \qquad \text{and} \qquad \text{Pr} = 0.7336$$

Analysis The outer diameter of insulated pipe is D_o = 4.6+2×3.5=11.6 cm = 0.116 m. The Reynolds number is



$$\text{Re} = \frac{\mathbf{V}_\infty D_o}{\upsilon} = \frac{(4 \text{ m/s})(0.116 \text{ m})}{1.426\times10^{-5} \text{ m}^2\text{/s}} = 3.254\times10^4$$

The Nusselt number for flow across a cylinder is determined from

$$Nu = \frac{hD_o}{k} = 0.3 + \frac{0.62\,\text{Re}^{0.5}\,\text{Pr}^{1/3}}{\left[1+(0.4/\text{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(3.254\times10^4)^{0.5}(0.7336)^{1/3}}{\left[1+(0.4/0.7336)^{2/3}\right]^{1/4}}\left[1+\left(\frac{3.254\times10^4}{282{,}000}\right)^{5/8}\right]^{4/5} = 107.0$$

and $$h_o = \frac{k}{D_o}Nu = \frac{0.02439 \text{ W/m}\cdot\text{°C}}{0.116 \text{ m}}(107.0) = 22.50 \text{ W/m}^2\cdot\text{°C}$$

Area of the outer surface of the pipe per m length of the pipe is

$$A_o = \pi D_o L = \pi(0.116 \text{ m})(1 \text{ m}) = 0.3644 \text{ m}^2$$

In steady operation, heat transfer from the steam through the pipe and the insulation to the outer surface (by first convection and then conduction) must be equal to the heat transfer from the outer surface to the surroundings (by simultaneous convection and radiation). That is,

$$\dot{Q} = \dot{Q}_{\text{pipe and insulation}} = \dot{Q}_{\text{surface to surroundings}}$$

Using the thermal resistance network, heat transfer from the steam to the outer surface is expressed as

$$R_{conv,i} = \frac{1}{h_i A_i} = \frac{1}{(80 \text{ W/m}^2\text{.°C})\left[\pi(0.04 \text{ m})(1 \text{ m})\right]} = 0.0995 \text{ °C/W}$$

$$R_{pipe} = \frac{\ln(r_2/r_1)}{2\pi kL} = \frac{\ln(2.3/2)}{2\pi(15 \text{ W/m.°C})(1 \text{ m})} = 0.0015 \text{ °C/W}$$

$$R_{insulation} = \frac{\ln(r_3/r_2)}{2\pi kL} = \frac{\ln(5.8/2.3)}{2\pi(0.038 \text{ W/m.°C})(1 \text{ m})} = 3.874 \text{ °C/W}$$

and $$\dot{Q}_{\text{pipe and ins}} = \frac{T_{\infty 1} - T_s}{R_{conv,i} + R_{pipe} + R_{insulation}} = \frac{(250 - T_s)\text{°C}}{(0.0995 + 0.0015 + 3.874) \text{ °C/W}}$$

Heat transfer from the outer surface can be expressed as

$$\dot{Q}_{\text{surface to surr, conv+rad}} = h_o A_o (T_s - T_{surr}) + \varepsilon A_o \sigma(T_s{}^4 - T_{surr}{}^4) = (22.50 \text{ W/m}^2\text{.°C})(0.3644 \text{ m}^2)(T_s - 3)\text{°C}$$
$$+ (0.3)(0.3644 \text{ m}^2)(5.67\times10^{-8} \text{ W/m}^2\text{.K}^4)\left[(T_s + 273 \text{ K})^4 - (3 + 273 \text{ K})^4\right]$$

Solving the two equations above simultaneously, the surface temperature and the heat transfer rate per m length of the pipe are determined to be

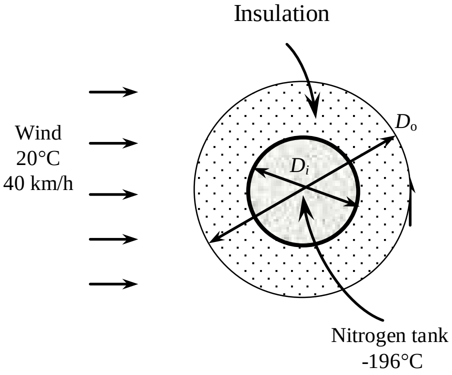
$$T_s = 9.9\text{°C and } \dot{Q} = \mathbf{60.4 \text{ W}} \quad \text{(per m length)}$$

7-101 A spherical tank filled with liquid nitrogen is exposed to winds. The rate of evaporation of the liquid nitrogen due to heat transfer from the air is to be determined for three cases.

Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties. **4** The pressure of air is 1 atm.

Properties The properties of air at 1 atm pressure and the free stream temperature of 20°C are (Table A-15)

$$k = 0.02514 \text{ W/m.°C}$$
$$\upsilon = 1.516\times10^{-5} \text{ m}^2\text{/s}$$
$$\mu_\infty = 1.825\times10^{-5} \text{ kg/m.s}$$
$$\mu_{s,@-196\,°\text{C}} = 5.023\times10^{-6} \text{ kg/m.s}$$
$$\text{Pr} = 0.7309$$



Analysis (*a*) When there is no insulation, $D = D_i = 4$ m, and the Reynolds number is

$$\text{Re} = \frac{V_\infty D}{\upsilon} = \frac{[(40\times1000/3600)\text{ m/s}](4\text{ m})}{1.516\times10^{-5}\text{ m}^2\text{/s}} = 2.932\times10^6$$

The Nusselt number is determined from

$$Nu = \frac{hD}{k} = 2 + \left[0.4\text{Re}^{0.5} + 0.06\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2 + \left[0.4(2.932\times10^6)^{0.5} + 0.06(2.932\times10^6)^{2/3}\right](0.7309)^{0.4}\left(\frac{1.825\times10^{-5}}{5.023\times10^{-6}}\right)^{1/4} = 2333$$

and $$h = \frac{k}{D}Nu = \frac{0.02514\text{ W/m.°C}}{4\text{ m}}(2333) = 14.66\text{ W/m}^2\text{.°C}$$

The rate of heat transfer to the liquid nitrogen is

$$\dot{Q} = hA_s(T_s - T_\infty) = h(\pi D^2)(T_s - T_\infty)$$
$$= (14.66\text{ W/m}^2\text{.°C})[\pi(4\text{ m})^2][(20-(-196)]\text{°C} = 159{,}200\text{ W}$$

The rate of evaporation of liquid nitrogen then becomes

$$\dot{Q} = \dot{m}h_{if} \longrightarrow \dot{m} = \frac{\dot{Q}}{h_{if}} = \frac{159.2\text{ kJ/s}}{198\text{ kJ/kg}} = \mathbf{0.804\ \ kg/s}$$

(*b*) Note that after insulation the outer surface temperature and diameter will change. Therefore we need to evaluate dynamic viscosity at a new surface temperature which we will assume to be -100°C. At -100°C, $\mu = 1.189\times10^{-5}$ kg/m.s . Noting that $D = D_0 = 4.1$ m, the Nusselt number becomes

$$\text{Re} = \frac{V_\infty D}{\upsilon} = \frac{[(40\times1000/3600)\text{ m/s}](4.1\text{ m})}{1.516\times10^{-5}\text{ m}^2\text{/s}} = 3.005\times10^6$$

$$Nu = \frac{hD}{k} = 2 + \left[0.4\text{Re}^{0.5} + 0.06\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2 + \left[0.4(3.005\times10^6)^{0.5} + 0.06(3.005\times10^6)^{2/3}\right](0.7309)^{0.4}\left(\frac{1.825\times10^{-5}}{1.189\times10^{-5}}\right)^{1/4} = 1910$$

and $$h = \frac{k}{D}Nu = \frac{0.02514\text{ W/m.°C}}{4.1\text{ m}}(1910) = 11.71\text{ W/m}^2\text{.°C}$$

The rate of heat transfer to the liquid nitrogen is

$$A_s = \pi D^2 = \pi(4.1\,\text{m})^2 = 52.81\,\text{m}^2$$

$$\dot{Q} = \frac{T_\infty - T_{s,\tan k}}{R_{insulation} + R_{conv}} = \frac{T_\infty - T_{s,\tan k}}{\dfrac{r_2 - r_1}{4\pi k r_1 r_2} + \dfrac{1}{hA_s}}$$

$$= \frac{[20-(-196)]°\text{C}}{\dfrac{(2.05-2)\,\text{m}}{4\pi(0.035\,\text{W/m.°C})(2.05\,\text{m})(2\,\text{m})} + \dfrac{1}{(11.71\,\text{W/m}^2\text{.°C})(52.81\,\text{m}^2)}} = 7361\,\text{W}$$

The rate of evaporation of liquid nitrogen then becomes

$$\dot{Q} = \dot{m}h_{if} \longrightarrow \dot{m} = \frac{\dot{Q}}{h_{if}} = \frac{7.361\,\text{kJ/s}}{198\,\text{kJ/kg}} = \mathbf{0.0372\ kg/s}$$

(*c*) We use the dynamic viscosity value at the new estimated surface temperature of 0°C to be $\mu = 1.729\times10^{-5}$ kg/m.s . Noting that $D = D_0$ = 4.04 m in this case, the Nusselt number becomes

$$\text{Re} = \frac{V_\infty D}{\upsilon} = \frac{[(40\times1000/3600)\,\text{m/s}](4.04\,\text{m})}{1.516\times10^{-5}\,\text{m}^2\text{/s}} = 2.961\times10^6$$

$$Nu = \frac{hD}{k} = 2 + \left[0.4\,\text{Re}^{0.5} + 0.06\,\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2 + \left[0.4(2.961\times10^6)^{0.5} + 0.06(2.961\times10^6)^{2/3}\right](0.7309)^{0.4}\left(\frac{1.825\times10^{-5}}{1.729\times10^{-5}}\right)^{1/4} = 1724$$

and $$h = \frac{k}{D}Nu = \frac{0.02514\,\text{W/m.°C}}{4.04\,\text{m}}(1724) = 10.73\,\text{W/m}^2\text{.°C}$$

The rate of heat transfer to the liquid nitrogen is

$$A_s = \pi D^2 = \pi(4.04\,\text{m})^2 = 51.28\,\text{m}^2$$

$$\dot{Q} = \frac{T_\infty - T_{s,\tan k}}{R_{insulation} + R_{conv}} = \frac{T_\infty - T_{s,\tan k}}{\dfrac{r_2 - r_1}{4\pi k r_1 r_2} + \dfrac{1}{hA_s}}$$

$$= \frac{[20-(-196)]°\text{C}}{\dfrac{(2.02-2)\,\text{m}}{4\pi(0.00005\,\text{W/m.°C})(2.02\,\text{m})(2\,\text{m})} + \dfrac{1}{(10.73\,\text{W/m}^2\text{.°C})(51.28\,\text{m}^2)}} = 27.4\,\text{W}$$

The rate of evaporation of liquid nitrogen then becomes

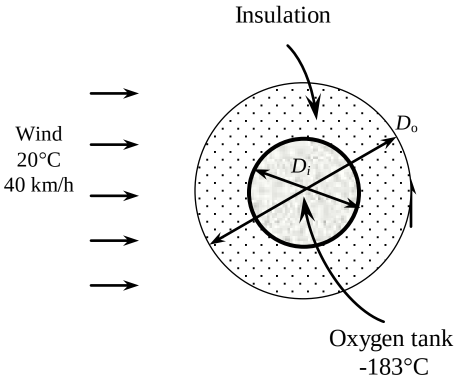
$$\dot{Q} = \dot{m}h_{if} \longrightarrow \dot{m} = \frac{\dot{Q}}{h_{if}} = \frac{0.0274\,\text{kJ/s}}{198\,\text{kJ/kg}} = \mathbf{1.38\times10^{-4}\ kg/s}$$

7-102 A spherical tank filled with liquid oxygen is exposed to ambient winds. The rate of evaporation of the liquid oxygen due to heat transfer from the air is to be determined for three cases.

Assumptions **1** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Air is an ideal gas with constant properties. **7** The pressure of air is 1 atm.

Properties The properties of air at 1 atm pressure and the free stream temperature of 20°C are (Table A-15)

$$k = 0.02514 \text{ W/m.°C}$$
$$\upsilon = 1.516\times10^{-5} \text{ m}^2\text{/s}$$
$$\mu_\infty = 1.825\times10^{-5} \text{ kg/m.s}$$
$$\mu_{s,@-183°\text{C}} = 6.127\times10^{-5} \text{ kg/m.s}$$
$$\text{Pr} = 0.7309$$



Analysis (*a*) When there is no insulation, $D = D_\text{i} = 4$ m, and the Reynolds number is

$$\text{Re} = \frac{V_\infty D}{\upsilon} = \frac{[(40\times1000/3600)\text{ m/s}](4\text{ m})}{1.516\times10^{-5}\text{ m}^2\text{/s}} = 2.932\times10^6$$

The Nusselt number is determined from

$$Nu = \frac{hD}{k} = 2 + \left[0.4\,\text{Re}^{0.5} + 0.06\,\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2 + \left[0.4(2.932\times10^6)^{0.5} + 0.06(2.932\times10^6)^{2/3}\right](0.7309)^{0.4}\left(\frac{1.825\times10^{-5}}{1.05\times10^{-5}}\right)^{1/4} = 2220$$

and $$h = \frac{k}{D}Nu = \frac{0.02514\text{ W/m.°C}}{4\text{ m}}(2220) = 13.95\text{ W/m}^2\text{.°C}$$

The rate of heat transfer to the liquid oxygen is

$$\dot{Q} = hA_s(T_s - T_\infty) = h(\pi D^2)(T_s - T_\infty) = (13.95\text{ W/m}^2\text{.°C})[\pi(4\text{ m})^2][(20-(-183)]\text{°C} = 142{,}372\text{ W}$$

The rate of evaporation of liquid oxygen then becomes

$$\dot{Q} = \dot{m}h_{if} \longrightarrow \dot{m} = \frac{\dot{Q}}{h_{if}} = \frac{142.4\text{ kJ/s}}{213\text{ kJ/kg}} = \mathbf{0.668\ kg/s}$$

(*b*) Note that after insulation the outer surface temperature and diameter will change. Therefore we need to evaluate dynamic viscosity at a new surface temperature which we will assume to be -100°C. At -100°C, $\mu = 1.189\times10^{-5}$ kg/m.s . Noting that $D = D_0 = 4.1$ m, the Nusselt number becomes

$$\text{Re} = \frac{V_\infty D}{\upsilon} = \frac{[(40\times1000/3600)\text{ m/s}](4.1\text{ m})}{1.516\times10^{-5}\text{ m}^2\text{/s}} = 3.005\times10^6$$

$$Nu = \frac{hD}{k} = 2 + \left[0.4\,\text{Re}^{0.5} + 0.06\,\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2 + \left[0.4(3.005\times10^6)^{0.5} + 0.06(3.005\times10^6)^{2/3}\right](0.7309)^{0.4}\left(\frac{1.825\times10^{-5}}{1.189\times10^{-5}}\right)^{1/4} = 1910$$

and $$h = \frac{k}{D}Nu = \frac{0.02514\text{ W/m.°C}}{4.1\text{ m}}(1910) = 11.71\text{ W/m}^2\text{.°C}$$

The rate of heat transfer to the liquid nitrogen is

$$A_s = \pi D^2 = \pi(4.1\,\mathrm{m})^2 = 52.81\,\mathrm{m}^2$$

$$\dot{Q} = \frac{T_\infty - T_{s,\tan k}}{R_{insulation} + R_{conv}} = \frac{T_\infty - T_{s,\tan k}}{\dfrac{r_2 - r_1}{4\pi k r_1 r_2} + \dfrac{1}{hA_s}}$$

$$= \frac{[20-(-183)]\mathrm{°C}}{\dfrac{(2.05-2)\,\mathrm{m}}{4\pi(0.035\,\mathrm{W/m.°C})(2.05\,\mathrm{m})(2\,\mathrm{m})} + \dfrac{1}{(11.71\,\mathrm{W/m^2.°C})(52.81\,\mathrm{m}^2)}} = 6918\,\mathrm{W}$$

The rate of evaporation of liquid nitrogen then becomes

$$\dot{Q} = \dot{m}h_{if} \longrightarrow \dot{m} = \frac{\dot{Q}}{h_{if}} = \frac{6.918\,\mathrm{kJ/s}}{213\,\mathrm{kJ/kg}} = \mathbf{0.0325\ kg/s}$$

(*c*) Again we use the dynamic viscosity value at the estimated surface temperature of 0°C to be $\mu = 1.729\times10^{-5}$ kg/m.s . Noting that $D = D_0 = 4.04$ m in this case, the Nusselt number becomes

$$\mathrm{Re} = \frac{V_\infty D}{\upsilon} = \frac{[(40\times1000/3600)\,\mathrm{m/s}](4.04\,\mathrm{m})}{1.516\times10^{-5}\,\mathrm{m^2/s}} = 2.961\times10^6$$

$$Nu = \frac{hD}{k} = 2 + \left[0.4\,\mathrm{Re}^{0.5} + 0.06\,\mathrm{Re}^{2/3}\right]\mathrm{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2 + \left[0.4(2.961\times10^6)^{0.5} + 0.06(2.961\times10^6)^{2/3}\right](0.713)^{0.4}\left(\frac{1.825\times10^{-5}}{1.729\times10^{-5}}\right)^{1/4} = 1724$$

and $$h = \frac{k}{D}Nu = \frac{0.02514\,\mathrm{W/m.°C}}{4.04\,\mathrm{m}}(1724) = 10.73\,\mathrm{W/m^2.°C}$$

The rate of heat transfer to the liquid nitrogen is

$$A_s = \pi D^2 = \pi(4.04\,\mathrm{m})^2 = 51.28\,\mathrm{m}^2$$

$$\dot{Q} = \frac{T_\infty - T_{s,\tan k}}{R_{insulation} + R_{conv}} = \frac{T_\infty - T_{s,\tan k}}{\dfrac{r_2 - r_1}{4\pi k r_1 r_2} + \dfrac{1}{hA_s}}$$

$$= \frac{[20-(-183)]\mathrm{°C}}{\dfrac{(2.02-2)\,\mathrm{m}}{4\pi(0.00005\,\mathrm{W/m.°C})(2.02\,\mathrm{m})(2\,\mathrm{m})} + \dfrac{1}{(10.73\,\mathrm{W/m^2.°C})(51.28\,\mathrm{m}^2)}} = 25.8\,\mathrm{W}$$

The rate of evaporation of liquid oxygen then becomes

$$\dot{Q} = \dot{m}h_{if} \longrightarrow \dot{m} = \frac{\dot{Q}}{h_{if}} = \frac{0.0258\,\mathrm{kJ/s}}{213\,\mathrm{kJ/kg}} = \mathbf{1.21\times10^{-4}\ kg/s}$$

7-103 A circuit board houses 80 closely spaced logic chips on one side. All the heat generated is conducted across the circuit board and is dissipated from the back side of the board to the ambient air, which is forced to flow over the surface by a fan. The temperatures on the two sides of the circuit board are to be determined.

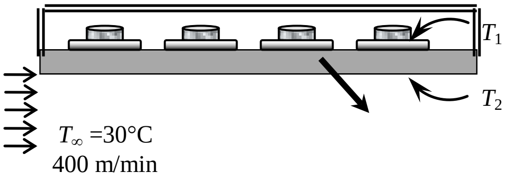
Assumptions **1** Steady operating conditions exist. **2** The critical Reynolds number is $\mathrm{Re}_{cr} = 5\times10^5$. **3** Radiation effects are negligible. **4** Air is an ideal gas with constant properties. **7** The pressure of air is 1 atm.

Properties Assuming a film temperature of 40°C, the properties of air are (Table A-15)

$$k = 0.02662 \text{ W/m.°C}$$
$$\upsilon = 1.702\times10^{-5} \text{ m}^2\text{/s}$$
$$\Pr = 0.7255$$

Analysis The Reynolds number is

$$\mathrm{Re}_L = \frac{V_\infty L}{\upsilon} = \frac{[(400/60)\text{ m/s}](0.18\text{ m})}{1.702\times10^{-5}\text{ m}^2\text{/s}} = 7.051\times10^4$$



which is less than the critical Reynolds number. Therefore, the flow is laminar. Using the proper relation for Nusselt number, heat transfer coefficient is determined to be

$$Nu = \frac{hL}{k} = 0.664\,\mathrm{Re}_L^{0.5}\,\Pr^{1/3} = 0.664(7.051\times10^4)^{0.5}(0.7255)^{1/3} = 158.4$$

$$h = \frac{k}{L}Nu = \frac{0.02662\text{ W/m.°C}}{0.18\text{ m}}(158.4) = 23.43\text{ W/m}^2\text{.°C}$$

The temperatures on the two sides of the circuit board are

$$\dot{Q} = hA_s(T_2 - T_\infty) \rightarrow T_2 = T_\infty + \frac{\dot{Q}}{hA_s}$$

$$= 30°\text{C} + \frac{(80\times0.06)\text{ W}}{(23.43\text{ W/m}^2\text{.°C})(0.12\text{ m})(0.18\text{ m})} = \mathbf{39.48°C}$$

$$\dot{Q} = \frac{kA_s}{L}(T_1 - T_2) \rightarrow T_1 = T_2 + \frac{\dot{Q}L}{kA_s}$$

$$= 39.48°\text{C} + \frac{(80\times0.06\text{ W})(0.003\text{ m})}{(16\text{ W/m.°C})(0.12\text{ m})(0.18\text{ m})} = \mathbf{39.52°C}$$

7-104E The equivalent wind chill temperature of an environment at 10°F at various winds speeds are

V = 10 mph: $T_{equiv} = 91.4-(91.4-T_{ambient})(0.475-0.0203V+0.304\sqrt{V})$

$$= 91.4-\left[91.4-(10°\text{ F})\right]\left[0.475-0.0203(10\text{ mph})+0.304\sqrt{10\text{ mph}}\right] = \mathbf{-9°\ F}$$

V = 20 mph: $T_{equiv} = 91.4-\left[91.4-(10°\text{ F})\right]\left[0.475-0.0203(20\text{ mph})+0.304\sqrt{20\text{ mph}}\right] = \mathbf{-24.9°\ F}$

V = 30 mph: $T_{equiv} = 91.4-\left[91.4-(10°\text{ F})\right]\left[0.475-0.0203(30\text{ mph})+0.304\sqrt{30\text{ mph}}\right] = \mathbf{-33.2°\ F}$

V = 40 mph: $T_{equiv} = 91.4-\left[91.4-(10°\text{ F})\right]\left[0.475-0.0203(40\text{ mph})+0.304\sqrt{40\text{ mph}}\right] = \mathbf{-37.7°\ F}$

In the last 3 cases, the person needs to be concerned about the possibility of freezing.

Chapter 8
INTERNAL FORCED CONVECTION

General Flow Analysis

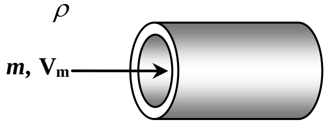
8-1C Liquids are usually transported in circular pipes because pipes with a circular cross-section can withstand large pressure differences between the inside and the outside without undergoing any distortion.

8-2C Reynolds number for flow in a circular tube of diameter D is expressed as

$$\mathrm{Re} = \frac{\mathbf{V}_m D}{\upsilon} \quad \text{where} \quad \mathbf{V}_\infty = \frac{\dot{m}}{\rho A_c} = \frac{\dot{m}}{\rho(\pi D^2/4)} = \frac{4\dot{m}}{\rho \pi D^2} \quad \text{and} \quad \upsilon = \frac{\mu}{\rho}$$

Substituting,

$$\mathrm{Re} = \frac{\mathbf{V}_m D}{\upsilon} = \frac{4\dot{m}D}{\rho \pi D^2 (\mu/\rho)} = \frac{4\dot{m}}{\pi D \mu}$$



8-3C Engine oil requires a larger pump because of its much larger density.

8-4C The generally accepted value of the Reynolds number above which the flow in a smooth pipe is turbulent is 4000.

8-5C For flow through non-circular tubes, the Reynolds number as well as the Nusselt number and the friction factor are based on the hydraulic diameter D_h defined as $D_h = \frac{4A_c}{p}$ where A_c is the cross-sectional area of the tube and p is its perimeter. The hydraulic diameter is defined such that it reduces to ordinary diameter D for circular tubes since $D_h = \frac{4A_c}{p} = \frac{4\pi D^2/4}{\pi D} = D$.

8-6C The region from the tube inlet to the point at which the boundary layer merges at the centerline is called the *hydrodynamic entry region*, and the length of this region is called *hydrodynamic entry length*. The entry length is much longer in laminar flow than it is in turbulent flow. But at very low Reynolds numbers, L_h is very small ($L_h = 1.2D$ at Re = 20).

8-7C The friction factor is highest at the tube inlet where the thickness of the boundary layer is zero, and decreases gradually to the fully developed value. The same is true for turbulent flow.

8-8C In turbulent flow, the tubes with rough surfaces have much higher friction factors than the tubes with smooth surfaces. In the case of laminar flow, the effect of surface roughness on the friction factor is negligible.

8-9C The friction factor f remains constant along the flow direction in the fully developed region in both laminar and turbulent flow.

8-10C The fluid viscosity is responsible for the development of the velocity boundary layer. For the idealized inviscid fluids (fluids with zero viscosity), there will be no velocity boundary layer.

8-11C The number of transfer units NTU is a measure of the heat transfer area and effectiveness of a heat transfer system. A small value of NTU (NTU < 5) indicates more opportunities for heat transfer whereas a large NTU value (NTU >5) indicates that heat transfer will not increase no matter how much we extend the length of the tube.

8-12C The logarithmic mean temperature difference $\Delta T_{\ln}$ is an exact representation of the average temperature difference between the fluid and the surface for the entire tube. It truly reflects the exponential decay of the local temperature difference. The error in using the arithmetic mean temperature increases to undesirable levels when ΔT_e differs from ΔT_i by great amounts. Therefore we should always use the logarithmic mean temperature.

8-13C The region of flow over which the thermal boundary layer develops and reaches the tube center is called the thermal entry region, and the length of this region is called the thermal entry length. The region in which the flow is both hydrodynamically (the velocity profile is fully developed and remains unchanged) and thermally (the dimensionless temperature profile remains unchanged) developed is called the fully developed region.

8-14C The heat flux will be higher near the inlet because the heat transfer coefficient is highest at the tube inlet where the thickness of thermal boundary layer is zero, and decreases gradually to the fully developed value.

8-15C The heat flux will be higher near the inlet because the heat transfer coefficient is highest at the tube inlet where the thickness of thermal boundary layer is zero, and decreases gradually to the fully developed value.

8-16C In the fully developed region of flow in a circular tube, the velocity profile will not change in the flow direction but the temperature profile may.

8-17C The hydrodynamic and thermal entry lengths are given as $L_h = 0.05\,\mathrm{Re}\,D$ and $L_t = 0.05\,\mathrm{Re}\,\mathrm{Pr}\,D$ for laminar flow, and $L_h \approx L_t \approx 10D$ in turbulent flow. Noting that $\mathrm{Pr} >> 1$ for oils, the thermal entry length is larger than the hydrodynamic entry length in laminar flow. In turbulent, the hydrodynamic and thermal entry lengths are independent of Re or Pr numbers, and are comparable in magnitude.

8-18C The hydrodynamic and thermal entry lengths are given as $L_h = 0.05\,\mathrm{Re}\,D$ and $L_t = 0.05\,\mathrm{Re}\,\mathrm{Pr}\,D$ for laminar flow, and $L_h \approx L_t \approx 10\,\mathrm{Re}$ in turbulent flow. Noting that $\mathrm{Pr} << 1$ for liquid metals, the thermal entry length is smaller than the hydrodynamic entry length in laminar flow. In turbulent, the hydrodynamic and thermal entry lengths are independent of Re or Pr numbers, and are comparable in magnitude.

8-19C In fluid flow, it is convenient to work with an average or mean velocity V_m and an average or mean temperature T_m which remain constant in incompressible flow when the cross-sectional area of the tube is constant. The V_m and T_m represent the velocity and temperature, respectively, at a cross section if all the particles were at the same velocity and temperature.

8-20C When the surface temperature of tube is constant, the appropriate temperature difference for use in the Newton's law of cooling is logarithmic mean temperature difference that can be expressed as

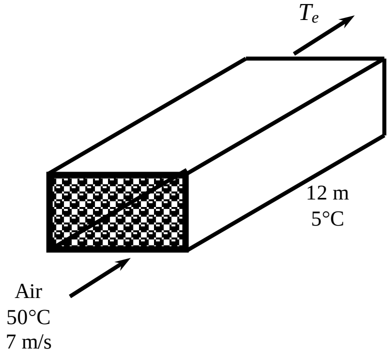
$$\Delta T_{\ln} = \frac{\Delta T_e - \Delta T_i}{\ln(\Delta T_e / \Delta T_i)}$$

8-21 Air flows inside a duct and it is cooled by water outside. The exit temperature of air and the rate of heat transfer are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The surface temperature of the duct is constant. **3** The thermal resistance of the duct is negligible.

Properties The properties of air at the anticipated average temperature of 30°C are (Table A-15)

$$\rho = 1.164\ \text{kg/m}^3$$
$$C_p = 1007\ \text{J/kg.°C}$$



Analysis The mass flow rate of water is

$$\dot{m} = \rho A_c \mathbf{V}_m = \rho\left(\frac{\pi D^2}{4}\right)\mathbf{V}_m$$

$$= (1.164\ \text{kg/m}^3)\frac{\pi(0.2\ \text{m})^2}{4}(7\ \text{m/s}) = 0.256\ \text{kg/s}$$

$$A_s = \pi DL = \pi(0.2\ \text{m})(12\ \text{m}) = 7.54\ \text{m}^2$$

The exit temperature of air is determined from

$$T_e = T_s - (T_s - T_i)e^{-hA_s/(\dot{m}C_p)} = 5-(5-50)e^{-\frac{(9.09)(7.54)}{(0.256)(1007)}} = \mathbf{8.74\ °C}$$

The logarithmic mean temperature difference and the rate of heat transfer are

$$\Delta T_{\ln} = \frac{T_e - T_i}{\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)} = \frac{8.74-50}{\ln\left(\frac{5-8.74}{5-50}\right)} = 16.59\text{°C}$$

$$\dot{Q} = hA_s\Delta T_{\ln} = (85\ \text{W/m}^2.\text{°C})(7.54\ \text{m}^2)(16.59\text{°C}) = 10{,}6333.41\times 10^4\ \text{W} = \mathbf{10{,}633\ W} \cong \mathbf{10.6\ kW}$$

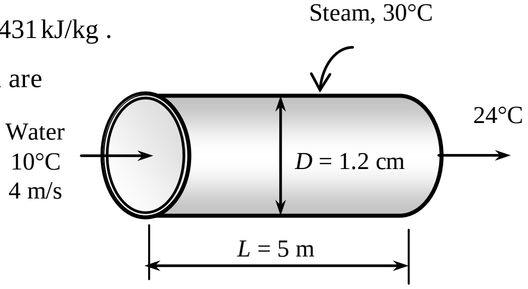
8-22 Steam is condensed by cooling water flowing inside copper tubes. The average heat transfer coefficient and the number of tubes needed are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The surface temperature of the pipe is constant. **3** The thermal resistance of the pipe is negligible.

Properties The properties of water at the average temperature of (10+24)/2=17°C are (Table A-9)

$$\rho = 998.7 \text{ kg/m}^3$$
$$C_p = 4184.5 \text{ J/kg.°C}$$

Also, the heat of vaporization of water at 30°C is $h_{fg} = 2431 \text{ kJ/kg}$.



Analysis The mass flow rate of water and the surface area are

$$\dot{m} = \rho A_c \mathbf{V}_m = \rho\left(\frac{\pi D^2}{4}\right)\mathbf{V}_m$$
$$= (998.7 \text{ kg/m}^3)\frac{\pi(0.012 \text{ m})^2}{4}(4 \text{ m/s}) = 0.4518 \text{ kg/s}$$

The rate of heat transfer for one tube is

$$\dot{Q} = \dot{m}C_p(T_e - T_i) = (0.4518 \text{ kg/s})(4184.5 \text{ J/kg.°C})(24 - 10\text{°C}) = 26{,}468 \text{ W}$$

The logarithmic mean temperature difference and the surface area are

$$\Delta T_{\ln} = \frac{T_e - T_i}{\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)} = \frac{24 - 10}{\ln\left(\frac{30 - 24}{30 - 10}\right)} = 11.63\text{°C}$$

$$A_s = \pi DL = \pi(0.012 \text{ m})(5 \text{ m}) = 0.1885 \text{ m}^2$$

The average heat transfer coefficient is determined from

$$\dot{Q} = hA_s\Delta T_{\ln} \longrightarrow h = \frac{\dot{Q}}{A_s\Delta T_{\ln}} = \frac{26{,}468 \text{ W}}{(0.1885 \text{ m}^2)(11.63\text{°C})}\left(\frac{1 \text{ kW}}{1000 \text{ W}}\right) = \mathbf{12.1 \text{ kW/m}^2.\text{°C}}$$

The total rate of heat transfer is determined from

$$\dot{Q}_{total} = \dot{m}_{cond}h_{fg} = (0.15 \text{ kg/s})(2431 \text{ kJ/kg}) = 364.65 \text{ kW}$$

Then the number of tubes becomes

$$N_{tube} = \frac{\dot{Q}_{total}}{\dot{Q}} = \frac{364{,}650 \text{ W}}{26{,}468 \text{ W}} = \mathbf{13.8}$$

8-23 Steam is condensed by cooling water flowing inside copper tubes. The average heat transfer coefficient and the number of tubes needed are to be determined.

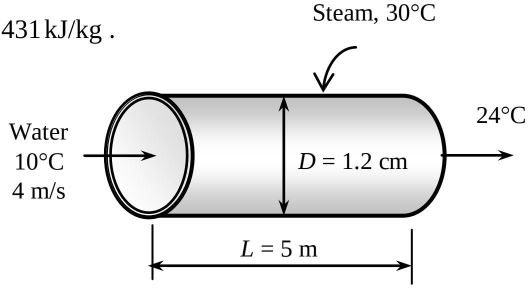
Assumptions **1** Steady operating conditions exist. **2** The surface temperature of the pipe is constant. **3** The thermal resistance of the pipe is negligible.

Properties The properties of water at the average temperature of (10+24)/2=17°C are (Table A-9)

$$\rho = 998.7 \text{ kg/m}^3$$

$$C_p = 4184.5 \text{ J/kg.°C}$$

Also, the heat of vaporization of water at 30°C is $h_{fg} = 2431 \text{ kJ/kg}$.



Analysis The mass flow rate of water is

$$\dot{m} = \rho A_c \mathbf{V}_m = \rho\left(\frac{\pi D^2}{4}\right)\mathbf{V}_m$$

$$= (998.7 \text{ kg/m}^3)\frac{\pi(0.012 \text{ m})^2}{4}(4 \text{ m/s}) = 0.4518 \text{ kg/s}$$

The rate of heat transfer for one tube is

$$\dot{Q} = \dot{m}C_p(T_e - T_i) = (0.4518 \text{ kg/s})(4184.5 \text{ J/kg.°C})(24 - 10\text{°C}) = 26{,}468 \text{ W}$$

The logarithmic mean temperature difference and the surface area are

$$\Delta T_{\ln} = \frac{T_e - T_i}{\ln\left(\dfrac{T_s - T_e}{T_s - T_i}\right)} = \frac{24 - 10}{\ln\left(\dfrac{30 - 24}{30 - 10}\right)} = 11.63\text{°C}$$

$$A_s = \pi DL = \pi(0.012 \text{ m})(5 \text{ m}) = 0.1885 \text{ m}^2$$

The average heat transfer coefficient is determined from

$$\dot{Q} = hA_s\Delta T_{\ln} \longrightarrow h = \frac{\dot{Q}}{A_s\Delta T_{\ln}} = \frac{26{,}468 \text{ W}}{(0.1885 \text{ m}^2)(11.63\text{°C})}\left(\frac{1 \text{ kW}}{1000 \text{ W}}\right) = \mathbf{12.1\,kW/m^2.°C}$$

The total rate of heat transfer is determined from

$$\dot{Q}_{total} = \dot{m}_{cond}h_{fg} = (0.60 \text{ kg/s})(2431 \text{ kJ/kg}) = 1458.6 \text{ kW}$$

Then the number of tubes becomes

$$N_{tube} = \frac{\dot{Q}_{total}}{\dot{Q}} = \frac{1{,}458{,}600 \text{ W}}{26{,}468 \text{ W}} = \mathbf{55.1}$$

8-24 Combustion gases passing through a tube are used to vaporize waste water. The tube length and the rate of evaporation of water are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The surface temperature of the pipe is constant. **3** The thermal resistance of the pipe is negligible. **4** Air properties are to be used for exhaust gases.

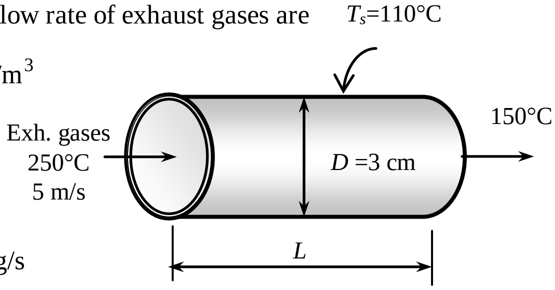
Properties The properties of air at the average temperature of (250+150)/2=200°C are (Table A-15)

$$C_p = 1023\ \text{J/kg.°C}$$

$$R = 0.287\ \text{kJ/kg.K}$$

Also, the heat of vaporization of water at 1 atm or 100°C is $h_{fg} = 2257\ \text{kJ/kg}$.

Analysis The density of air at the inlet and the mass flow rate of exhaust gases are



$$\rho = \frac{P}{RT} = \frac{115\ \text{kPa}}{(0.287\ \text{kJ/kg.K})(250+273\ \text{K})} = 0.7662\ \text{kg/m}^3$$

$$\dot{m} = \rho A_c \mathbf{V}_m = \rho\left(\frac{\pi D^2}{4}\right)\mathbf{V}_m$$

$$= (0.7662\ \text{kg/m}^3)\frac{\pi(0.03\ \text{m})^2}{4}(5\ \text{m/s}) = 0.002708\ \text{kg/s}$$

The rate of heat transfer is

$$\dot{Q} = \dot{m}C_p(T_i - T_e) = (0.002708\ \text{kg/s})(1023\ \text{J/kg.°C})(250-150\text{°C}) = 276.9\ \text{W}$$

The logarithmic mean temperature difference and the surface area are

$$\Delta T_{\ln} = \frac{T_e - T_i}{\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)} = \frac{150-250}{\ln\left(\frac{110-150}{110-250}\right)} = 79.82\text{°C}$$

$$\dot{Q} = hA_s\Delta T_{\ln} \longrightarrow A_s = \frac{\dot{Q}}{h\Delta T_{\ln}} = \frac{276.9\ \text{W}}{(120\ \text{W/m}^2.\text{°C})(79.82\text{°C})} = 0.02891\ \text{m}^2$$

Then the tube length becomes

$$A_s = \pi DL \longrightarrow L = \frac{A_s}{\pi D} = \frac{0.02891\ \text{m}^2}{\pi(0.03\ \text{m})} = 0.3067\ \text{m} = \mathbf{30.7\ cm}$$

The rate of evaporation of water is determined from

$$\dot{Q} = \dot{m}_{evap}h_{fg} \longrightarrow \dot{m}_{evap} = \frac{\dot{Q}}{h_{fg}} = \frac{(0.2769\ \text{kW})}{(2257\ \text{kJ/kg})} = 0.0001227\ \text{kg/s} = \mathbf{0.442\ kg/h}$$

8-25 Combustion gases passing through a tube are used to vaporize waste water. The tube length and the rate of evaporation of water are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The surface temperature of the pipe is constant. **3** The thermal resistance of the pipe is negligible. **4** Air properties are to be used for exhaust gases.

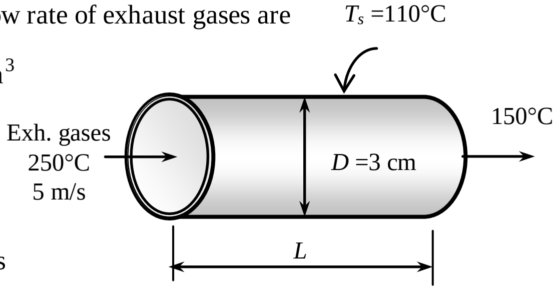
Properties The properties of air at the average temperature of (250+150)/2=200°C are (Table A-15)

$$C_p = 1023\ \text{J/kg.°C}$$

$$R = 0.287\ \text{kJ/kg.K}$$

Also, the heat of vaporization of water at 1 atm or 100°C is $h_{fg} = 2257\ \text{kJ/kg}$.

Analysis The density of air at the inlet and the mass flow rate of exhaust gases are



$$\rho = \frac{P}{RT} = \frac{115\ \text{kPa}}{(0.287\ \text{kJ/kg.K})(250+273\ \text{K})} = 0.7662\ \text{kg/m}^3$$

$$\dot{m} = \rho A_c \mathbf{V}_m = \rho\left(\frac{\pi D^2}{4}\right)\mathbf{V}_m$$

$$= (0.7662\ \text{kg/m}^3)\frac{\pi(0.03\ \text{m})^2}{4}(5\ \text{m/s}) = 0.002708\ \text{kg/s}$$

The rate of heat transfer is

$$\dot{Q} = \dot{m}C_p(T_i - T_e) = (0.002708\ \text{kg/s})(1023\ \text{J/kg.°C})(250-150\text{°C}) = 276.9\ \text{W}$$

The logarithmic mean temperature difference and the surface area are

$$\Delta T_{\ln} = \frac{T_e - T_i}{\ln\left(\dfrac{T_s - T_e}{T_s - T_i}\right)} = \frac{150-250}{\ln\left(\dfrac{110-150}{110-250}\right)} = 79.82\text{°C}$$

$$\dot{Q} = hA_s\Delta T_{\ln} \longrightarrow A_s = \frac{\dot{Q}}{h\Delta T_{\ln}} = \frac{276.9\ \text{W}}{(60\ \text{W/m}^2.\text{°C})(79.82\text{°C})} = 0.05782\ \text{m}^2$$

Then the tube length becomes

$$A_s = \pi DL \longrightarrow L = \frac{A_s}{\pi D} = \frac{0.05782\ \text{m}^2}{\pi(0.03\ \text{m})} = 0.6135\ \text{m} = \mathbf{61.4\ cm}$$

The rate of evaporation of water is determined from

$$\dot{Q} = \dot{m}_{evap}h_{fg} \longrightarrow \dot{m}_{evap} = \frac{\dot{Q}}{h_{fg}} = \frac{(0.2769\ \text{kW})}{(2257\ \text{kJ/kg})} = 0.0001227\ \text{kg/s} = \mathbf{0.442\ kg/h}$$

Laminar and Turbulent Flow in Tubes

8-26C The friction factor for flow in a tube is proportional to the pressure drop. Since the pressure drop along the flow is directly related to the power requirements of the pump to maintain flow, the friction factor is also proportional to the power requirements. The applicable relations are

$$\Delta P = f\,\frac{L}{D}\frac{\rho V^2}{2} \quad \text{and} \quad \dot{W}_{\text{pump}} = \frac{\dot{m}\Delta P}{\rho}$$

8-27C The shear stress at the center of a circular tube during fully developed laminar flow is zero since the shear stress is proportional to the velocity gradient, which is zero at the tube center.

8-28C Yes, the shear stress at the surface of a tube during fully developed turbulent flow is maximum since the shear stress is proportional to the velocity gradient, which is maximum at the tube surface.

8-29C In fully developed flow in a circular pipe with negligible entrance effects, if the length of the pipe is doubled, the pressure drop will also *double* (the pressure drop is proportional to length).

8-30C Yes, the volume flow rate in a circular pipe with laminar flow can be determined by measuring the velocity at the centerline in the fully developed region, multiplying it by the cross-sectional area, and dividing the result by 2 since $\dot{V} = \mathbf{V}_{\text{ave}} A_c = (\mathbf{V}_{\text{max}}/2)A_c$.

8-31C No, the average velocity in a circular pipe in fully developed laminar flow **cannot** be determined by simply measuring the velocity at R/2 (midway between the wall surface and the centerline). The mean velocity is $\mathbf{V}_{\text{max}}$/2, but the velocity at R/2 is

$$\mathbf{V}(R/2) = \mathbf{V}_{\text{max}}\left(1 - \frac{r^2}{R^2}\right)_{r=R/2} = \frac{3\mathbf{V}_{\text{max}}}{4}$$

8-32C In fully developed laminar flow in a circular pipe, the pressure drop is given by

$$\Delta P = \frac{8\mu L\mathbf{V}_{\text{m}}}{R^2} = \frac{32\mu L\mathbf{V}_{\text{m}}}{D^2}$$

The mean velocity can be expressed in terms of the flow rate as $\mathbf{V}_{\text{m}} = \dfrac{\dot{V}}{A_c} = \dfrac{\dot{V}}{\pi D^2/4}$. Substituting,

$$\Delta P = \frac{8\mu L\mathbf{V}_{\text{m}}}{R^2} = \frac{32\mu L\mathbf{V}_{\text{m}}}{D^2} = \frac{32\mu L}{D^2}\frac{\dot{V}}{\pi D^2/4} = \frac{128\mu L\dot{V}}{\pi D^4}$$

Therefore, at constant flow rate and pipe length, the pressure drop is inversely proportional to the 4th power of diameter, and thus reducing the pipe diameter by half will increase the pressure drop **by a factor of 16** .

8-33C In fully developed laminar flow in a circular pipe, the pressure drop is given by

$$\Delta P = \frac{8\mu L\mathbf{V}_{\text{m}}}{R^2} = \frac{32\mu L\mathbf{V}_{\text{m}}}{D^2}$$

When the flow rate and thus mean velocity are held constant, the pressure drop becomes proportional to viscosity. Therefore, pressure drop will be **reduced by half** when the viscosity is reduced by half.

8-34C The tubes with rough surfaces have much higher heat transfer coefficients than the tubes with smooth surfaces. In the case of laminar flow, the effect of surface roughness on the heat transfer coefficient is negligible.

8-35 The flow rate through a specified water pipe is given. The pressure drop and the pumping power requirements are to be determined.

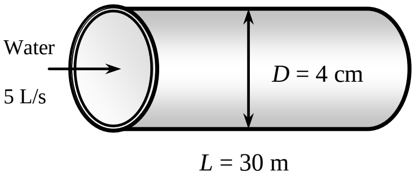
Assumptions **1** The flow is steady and incompressible. **2** The entrance effects are negligible, and thus the flow is fully developed. **3** The pipe involves no components such as bends, valves, and connectors. **4** The piping section involves no work devices such as pumps and turbines.

Properties The density and dynamic viscosity of water are given to be ρ = 999.1 kg/m^3 and μ = 1.138×10^{-3} kg/m·s, respectively. The roughness of stainless steel is 0.002 mm (Table 8-3).

Analysis First we calculate the mean velocity and the Reynolds number to determine the flow regime:

$$\mathbf{V}_m = \frac{\dot V}{A_c} = \frac{\dot V}{\pi D^2/4} = \frac{0.005\,\text{m}^3/s}{\pi(0.04\,\text{m})^2/4} = 3.98\,\text{m}/s$$

$$\text{Re} = \frac{\rho \mathbf{V}_m D}{\mu} = \frac{(999.1\,\text{kg/m}^3)(3.98\,\text{m/s})(0.04\,\text{m})}{1.138\times10^{-3}\ \text{kg/m}\cdot\text{s}} = 1.40\times10^5$$



which is greater than 10,000. Therefore, the flow is turbulent. The relative roughness of the pipe is

$$\varepsilon/D = \frac{2\times10^{-6}\ \text{m}}{0.04\,\text{m}} = 5\times10^{-5}$$

The friction factor can be determined from the Moody chart, but to avoid the reading error, we determine it from the Colebrook equation using an equation solver (or an iterative scheme),

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right) \rightarrow \frac{1}{\sqrt{f}} = -2.0\log\left(\frac{5\times10^{-5}}{3.7} + \frac{2.51}{1.40\times10^5\sqrt{f}}\right)$$

It gives f = 0.0171. Then the pressure drop and the required power input become

$$\Delta P = f\,\frac{L}{D}\frac{\rho \mathbf{V}_m^2}{2} = 0.0171\frac{30\,\text{m}}{0.04\,\text{m}}\frac{(999.1\,\text{kg/m}^3)(3.98\,\text{m/s})^2}{2}\left(\frac{1\,\text{kN}}{1000\,\text{kg}\cdot\text{m/s}}\right)\left(\frac{1\,\text{kPa}}{1\,\text{kN/m}^2}\right) = 101.5\ \text{kPa}$$

$$\dot W_{\text{pump,u}} = \dot V\Delta P = (0.005\,\text{m}^3/s)(101.5\,\text{kPa})\left(\frac{1\,\text{kW}}{1\,\text{kPa}\cdot\text{m}^3/\text{s}}\right) = \mathbf{0.508\,kW}$$

Therefore, useful power input in the amount of 0.508 kW is needed to overcome the frictional losses in the pipe.

Discussion The friction factor could also be determined easily from the explicit Haaland relation. It would give f = 0.0169, which is sufficiently close to 0.0171. Also, the friction factor corresponding to ε = 0 in this case is 0.0168, which indicates that stainless steel pipes can be assumed to be smooth with an error of about 2%. Also, the power input determined is the mechanical power that needs to be imparted to the fluid. The shaft power will be more than this due to pump inefficiency; the electrical power input will be even more due to motor inefficiency.

8-36 In fully developed laminar flow in a circular pipe, the velocity at $r = R/2$ is measured. The velocity at the center of the pipe ($r = 0$) is to be determined.

Assumptions The flow is steady, laminar, and fully developed.

Analysis The velocity profile in fully developed laminar flow in a circular pipe is given by

$$\mathbf{V}(r) = \mathbf{V}_{\max}\left(1 - \frac{r^2}{R^2}\right)$$

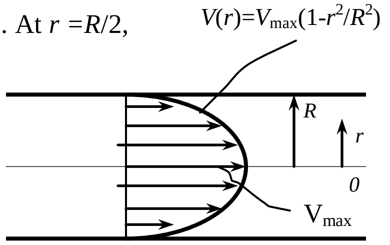
where $\mathbf{V}_{\max}$ is the maximum velocity which occurs at pipe center, $r = 0$. At $r = R/2$,

$$\mathbf{V}(R/2) = \mathbf{V}_{\max}\left(1 - \frac{(R/2)^2}{R^2}\right) = \mathbf{V}_{\max}\left(1 - \frac{1}{4}\right) = \frac{3\mathbf{V}_{\max}}{4}$$

Solving for $\mathbf{V}_{\max}$ and substituting,

$$\mathbf{V}_{\max} = \frac{4\mathbf{V}(R/2)}{3} = \frac{4(6\text{ m/s})}{3} = \mathbf{8\ m/s}$$

which is the velocity at the pipe center.



8-37 The velocity profile in fully developed laminar flow in a circular pipe is given. The mean and maximum velocities are to be determined.

Assumptions The flow is steady, laminar, and fully developed.

Analysis The velocity profile in fully developed laminar flow in a circular pipe is given by

$$\mathbf{V}(r) = \mathbf{V}_{\max}\left(1 - \frac{r^2}{R^2}\right)$$

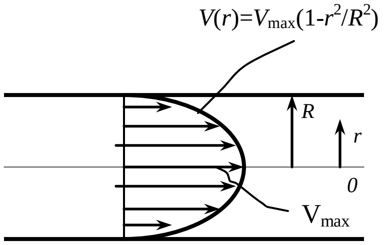
The velocity profile in this case is given by

$$\mathbf{V}(r) = 4(1 - r^2/R^2)$$

Comparing the two relations above gives the maximum velocity to be $\mathbf{V}_{\max} = 4$ m/s. Then the mean velocity and volume flow rate become

$$\mathbf{V}_m = \frac{\mathbf{V}_{\max}}{2} = \frac{4\text{ m/s}}{2} = \mathbf{2\ m/s}$$

$$\dot{V} = \mathbf{V}_m A_c = \mathbf{V}_m(\pi R^2) = (2\text{ m/s})[\pi(0.02\text{ m})^2] = \mathbf{0.00251\ m^3/s}$$



8-38 The velocity profile in fully developed laminar flow in a circular pipe is given. The mean and maximum velocities are to be determined.

Assumptions The flow is steady, laminar, and fully developed.

Analysis The velocity profile in fully developed laminar flow in a circular pipe is given by

$$\mathbf{V}(r) = \mathbf{V}_{\max}\left(1 - \frac{r^2}{R^2}\right)$$

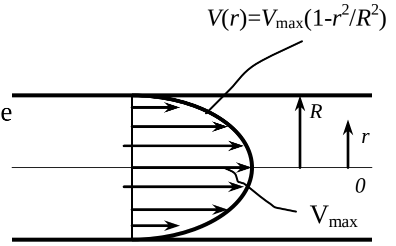
The velocity profile in this case is given by

$$\mathbf{V}(r) = 4(1 - r^2/R^2)$$

Comparing the two relations above gives the maximum velocity to be $\mathbf{V}_{\max} = 4$ m/s. Then the mean velocity and volume flow rate become

$$\mathbf{V}_m = \frac{\mathbf{V}_{\max}}{2} = \frac{4\text{ m/s}}{2} = \mathbf{2\ m/s}$$

$$\dot{V} = \mathbf{V}_m A_c = \mathbf{V}_m(\pi R^2) = (2\text{ m/s})[\pi(0.05\text{ m})^2] = \mathbf{0.0157\ m^3/s}$$



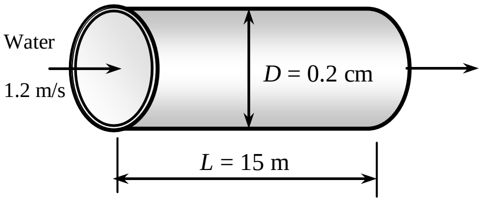
8-39 The average flow velocity in a pipe is given. The pressure drop and the pumping power are to be determined.

Assumptions **1** The flow is steady and incompressible. **2** The entrance effects are negligible, and thus the flow is fully developed. **3** The pipe involves no components such as bends, valves, and connectors. **4** The piping section involves no work devices such as pumps and turbines.

Properties The density and dynamic viscosity of water are given to be $\rho = 999.7\ \text{kg/m}^3$ and $\mu = 1.307\times10^{-3}$ kg/m·s, respectively.

Analysis (*a*) First we need to determine the flow regime. The Reynolds number of the flow is

$$\text{Re} = \frac{\rho \mathbf{V}_m D}{\mu} = \frac{(999.7\ \text{kg/m}^3)(1.2\ \text{m/s})(2\times10^{-3}\ \text{m})}{1.307\times10^{-3}\ \text{kg/m}\cdot\text{s}} = 1836$$



which is less than 2300. Therefore, the flow is laminar. Then the friction factor and the pressure drop become

$$f = \frac{64}{\text{Re}} = \frac{64}{1836} = 0.0349$$

$$\Delta P = f\frac{L}{D}\frac{\rho \mathbf{V}_m^2}{2} = 0.0349\frac{15\ \text{m}}{0.002\ \text{m}}\frac{(999.7\ \text{kg/m}^3)(1.2\ \text{m/s})^2}{2}\left(\frac{1\ \text{kN}}{1000\ \text{kg}\cdot\text{m/s}}\right)\left(\frac{1\ \text{kPa}}{1\ \text{kN/m}^2}\right) = \mathbf{188\ kPa}$$

(*b*) The volume flow rate and the pumping power requirements are

$$\dot{V} = \mathbf{V}_m A_c = \mathbf{V}_m(\pi D^2/4) = (1.2\ \text{m/s})[\pi(0.002\ \text{m})^2/4] = 3.77\times10^{-6}\ \text{m}^3/s$$

$$\dot{W}_{\text{pump}} = \dot{V}\Delta P = (3.77\times10^{-6}\ \text{m}^3/s)(188\ \text{kPa})\left(\frac{1000\ \text{W}}{1\ \text{kPa}\cdot\text{m}^3/\text{s}}\right) = \mathbf{0.71\ W}$$

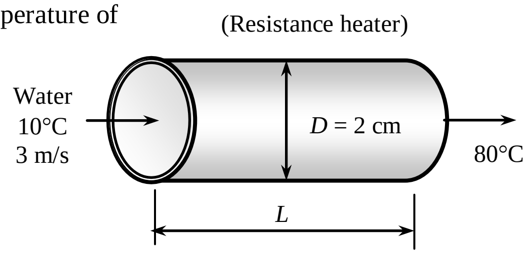
Therefore, power input in the amount of 0.71 W is needed to overcome the frictional losses in the flow due to viscosity.

8-40 Water is to be heated in a tube equipped with an electric resistance heater on its surface. The power rating of the heater and the inner surface temperature are to be determined.

Assumptions **1** Steady flow conditions exist. **2** The surface heat flux is uniform. **3** The inner surfaces of the tube are smooth.

Properties The properties of water at the average temperature of (80+10) / 2 = 45°C are (Table A-9)

$$\rho = 990.1\ \text{kg/m}^3$$
$$k = 0.637\ \text{W/m.°C}$$
$$\upsilon = \mu/\rho = 0.602\times10^{-6}\ \text{m}^2\text{/s}$$
$$C_p = 4180\ \text{J/kg.°C}$$
$$\text{Pr} = 3.91$$



Analysis The power rating of the resistance heater is

$$\dot{m} = \rho\dot{V} = (990.1\ \text{kg/m}^3)(0.008\ \text{m}^3\text{/min}) = 7.921\ \text{kg/min} = 0.132\ \text{kg/s}$$

$$\dot{Q} = \dot{m}C_p(T_e - T_i) = (0.132\ \text{kg/s})(4180\ \text{J/kg.°C})(80-10)\text{°C} = \mathbf{38{,}627\ W}$$

The velocity of water and the Reynolds number are

$$\mathbf{V}_m = \frac{\dot{V}}{A_c} = \frac{(8\times10^{-3}/60)\ \text{m}^3/\text{s}}{\pi(0.02\ \text{m})^2/4} = 0.4244\ \text{m/s}$$

$$\text{Re} = \frac{\mathbf{V}_m D_h}{\upsilon} = \frac{(0.4244\ \text{m/s})(0.02\ \text{m})}{0.602\times10^{-6}\ \text{m}^2\text{/s}} = 14{,}101$$

which is greater than 10,000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D = 10(0.02\ \text{m}) = 0.20\ \text{m}$$

which is much shorter than the total length of the duct. Therefore, we can assume fully developed turbulent flow in the entire duct, and determine the Nusselt number from

$$Nu = \frac{hD_h}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.4} = 0.023(14{,}101)^{0.8}(3.91)^{0.4} = 82.79$$

Heat transfer coefficient is

$$h = \frac{k}{D_h}Nu = \frac{0.637\ \text{W/m.°C}}{0.02\ \text{m}}(82.79) = 2637\ \text{W/m}^2\text{.°C}$$

Then the inner surface temperature of the pipe at the exit becomes

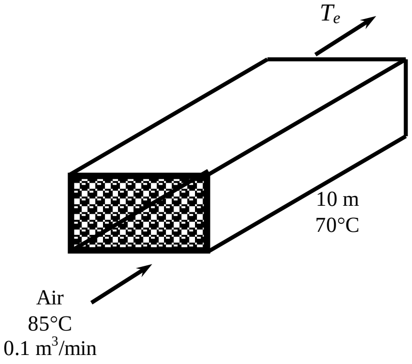
$$\dot{Q} = hA_s(T_{s,e} - T_e)$$
$$38{,}627\ \text{W} = (2637\ \text{W/m}^2\text{.°C})[\pi(0.02\ \text{m})(7\ \text{m})](T_s - 80)\text{°C}$$
$$T_{s,e} = \mathbf{113.3°C}$$

8-41 Flow of hot air through uninsulated square ducts of a heating system in the attic is considered. The exit temperature and the rate of heat loss are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The inner surfaces of the duct are smooth. **3** Air is an ideal gas with constant properties. **4** The pressure of air is 1 atm.

Properties We assume the bulk mean temperature for air to be 80°C since the mean temperature of air at the inlet will drop somewhat as a result of heat loss through the duct whose surface is at a lower temperature. The properties of air at 1 atm and this temperature are (Table A-15)

$$\rho = 0.9994 \text{ kg/m}^3$$
$$k = 0.02953 \text{ W/m.°C}$$
$$\upsilon = 2.097 \times 10^{-5} \text{ m}^2\text{/s}$$
$$C_p = 1008 \text{ J/kg.°C}$$
$$\Pr = 0.7154$$



Analysis The characteristic length that is the hydraulic diameter, the mean velocity of air, and the Reynolds number are

$$D_h = \frac{4A_c}{P} = \frac{4a^2}{4a} = a = 0.15 \text{ m}$$

$$\mathbf{V}_m = \frac{\dot{V}}{A_c} = \frac{0.10 \text{ m}^3\text{/s}}{(0.15 \text{ m})^2} = 4.444 \text{ m/s}$$

$$\text{Re} = \frac{\mathbf{V}_m D_h}{\upsilon} = \frac{(4.444 \text{ m/s})(0.15 \text{ m})}{2.097 \times 10^{-5} \text{ m}^2\text{/s}} = 31{,}791$$

which is greater than 10,0000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D_h = 10(0.15 \text{ m}) = 1.5 \text{ m}$$

which is much shorter than the total length of the duct. Therefore, we can assume fully developed turbulent flow in the entire duct, and determine the Nusselt number from

$$Nu = \frac{hD_h}{k} = 0.023\,\text{Re}^{0.8}\,\Pr^{0.3} = 0.023(31{,}791)^{0.8}(0.7154)^{0.3} = 83.16$$

Heat transfer coefficient is

$$h = \frac{k}{D_h} Nu = \frac{0.02953 \text{ W/m.°C}}{0.15 \text{ m}}(83.16) = 16.37 \text{ W/m}^2\text{.°C}$$

Next we determine the exit temperature of air,

$$A_s = 4aL = 4(0.15 \text{ m})(10 \text{ m}) = 6 \text{ m}^2$$
$$\dot{m} = \rho\dot{V} = (0.9994 \text{ kg/m}^3)(0.10 \text{ m}^3\text{/s}) = 0.09994 \text{ kg/s}$$

$$T_e = T_s - (T_s - T_i)e^{-hA/(\dot{m}C_p)} = 70 - (70 - 85)e^{-\frac{(16.37)(6)}{(0.09994)(1008)}} = \mathbf{75.7°C}$$

Then the logarithmic mean temperature difference and the rate of heat loss from the air becomes

$$\Delta T_{\ln} = \frac{T_e - T_i}{\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)} = \frac{75.7 - 85}{\ln\left(\frac{70 - 75.7}{70 - 85}\right)} = 9.58\text{°C}$$

$$\dot{Q} = hA_s\Delta T_{\ln} = (16.37 \text{ W/m}^2\text{.°C})(6 \text{ m}^2)(9.58\text{°C}) = \mathbf{941.1\ W}$$

Note that the temperature of air drops by almost 10°C as it flows in the duct as a result of heat loss.

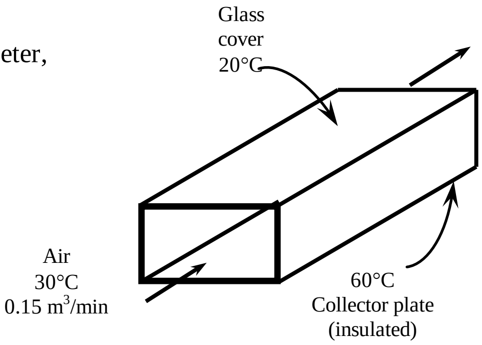
8-43 Air enters the constant spacing between the glass cover and the plate of a solar collector. The net rate of heat transfer and the temperature rise of air are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The inner surfaces of the spacing are smooth. **3** Air is an ideal gas with constant properties. **4** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and estimated average temperature of 35°C are (Table A-15)

$$\rho = 1.146 \text{kg/m}^3 \qquad C_p = 1007 \text{ J/kg.°C}$$
$$k = 0.02625 \text{ W/m.°C} \qquad \Pr = 0.7268$$
$$\upsilon = 1.655\times10^{-5} \text{ m}^2\text{/s}$$

Analysis Mass flow rate, cross sectional area, hydraulic diameter, mean velocity of air and the Reynolds number are



$$\dot{m} = \rho\dot{V} = (1.146 \text{ kg/m}^3)(0.15 \text{ m}^3\text{/s}) = 0.1719 \text{ kg/s}$$

$$A_c = (1 \text{ m})(0.03 \text{ m}) = 0.03 \text{ m}^2$$

$$D_h = \frac{4A_c}{P} = \frac{4(0.03 \text{ m}^2)}{2(1 \text{ m} + 0.03 \text{ m})} = 0.05825 \text{ m}$$

$$V_m = \frac{\dot{V}}{A_c} = \frac{0.15 \text{ m}^3\text{ / s}}{0.03 \text{ m}^2} = 5 \text{ m / s}$$

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(5 \text{ m/s})(0.05825 \text{ m})}{1.655\times10^{-5} \text{ m}^2\text{/s}} = 17{,}606$$

which is greater than 10,000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D_h = 10(0.05825 \text{ m}) = 0.5825 \text{ m}$$

which are much shorter than the total length of the collector. Therefore, we can assume fully developed turbulent flow in the entire collector, and determine the Nusselt number from

$$Nu = \frac{hD_h}{k} = 0.023\,\text{Re}^{0.8}\,\Pr^{0.4} = 0.023(17{,}606)^{0.8}(0.7268)^{0.4} = 50.45$$

and $$h = \frac{k}{D_h}Nu = \frac{0.02625 \text{ W/m.°C}}{0.05825 \text{ m}}(50.45) = 22.73 \text{ W/m}^2\text{.°C}$$

The exit temperature of air can be calculated using the "average" surface temperature as

$$A_s = 2(5 \text{ m})(1 \text{ m}) = 10 \text{ m}^2$$

$$T_{s,ave} = \frac{60+20}{2} = 40°\text{C}$$

$$T_e = T_{s,ave} - (T_{s,ave} - T_i)\exp\left(-\frac{hA_s}{\dot{m}C_p}\right) = 40 - (40-30)\exp\left(-\frac{22.73\times10}{0.1718\times1007}\right) = 37.31°\text{C}$$

The temperature rise of air is

$$\Delta T = 37.3°\text{C} - 30°\text{C} = \mathbf{7.3°C}$$

The logarithmic mean temperature difference and the heat loss from the glass are

$$\Delta T_{\ln,glass} = \frac{T_e - T_i}{\ln\frac{T_s - T_e}{T_s - T_i}} = \frac{37.31-30}{\ln\frac{20-37.31}{20-30}} = 13.32°\text{C}$$

$$\dot{Q}_{glass} = hA_s\Delta T_{\ln} = (22.73 \text{ W/m}^2\text{.°C})(5 \text{ m}^2)(13.32°\text{C}) = 1514 \text{ W}$$

The logarithmic mean temperature difference and the heat gain of the absorber are

$$\Delta T_{\ln,absorber} = \frac{T_e - T_i}{\ln\frac{T_s - T_e}{T_s - T_i}} = \frac{37.31 - 30}{\ln\frac{60 - 37.31}{60 - 30}} = 26.17°\text{C}$$

$$\dot{Q}_{absorber} = hA\Delta T_{\ln} = (22.73\ \text{W/m}^2.°\text{C})(5\ \text{m}^2)(26.17°\text{C}) = 2975\ \text{W}$$

Then the net rate of heat transfer becomes

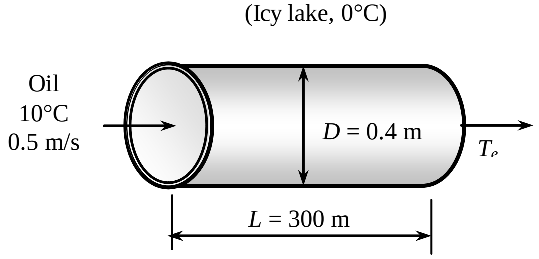
$$\dot{Q}_{net} = 2975 - 1514 = \mathbf{1461\ W}$$

8-44 Oil flows through a pipeline that passes through icy waters of a lake. The exit temperature of the oil and the rate of heat loss are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The surface temperature of the pipe is very nearly 0°C. **3** The thermal resistance of the pipe is negligible. **4** The inner surfaces of the pipeline are smooth. **5** The flow is hydrodynamically developed when the pipeline reaches the lake.

Properties The properties of oil at 10°C are (Table A-13)

$$\rho = 893.5\ \text{kg/m}^3, \qquad k = 0.146\ \text{W/m.°C}$$
$$\mu = 2.325\ \text{kg/m.s}, \qquad \upsilon = 2591\times10^{-6}\ \text{m}^2/\text{s}$$
$$C_p = 1838\ \text{J/kg.°C}, \qquad \text{Pr} = 28750$$



Analysis (a) The Reynolds number in this case is

$$\text{Re} = \frac{\mathbf{V}_m D_h}{\upsilon} = \frac{(0.5\ \text{m/s})(0.4\ \text{m})}{2591\times10^{-6}\ \text{m}^2/\text{s}} = 77.19$$

which is less than 2300. Therefore, the flow is laminar, and the thermal entry length is roughly

$$L_t = 0.05\,\text{Re}\,\text{Pr}\,D = 0.05(77.19)(28750)(0.4\ \text{m}) = 44{,}384\ \text{m}$$

which is much longer than the total length of the pipe. Therefore, we assume thermally developing flow, and determine the Nusselt number from

$$Nu = \frac{hD}{k} = 3.66 + \frac{0.065(D/L)\,\text{Re}\,\text{Pr}}{1+0.04\left[(D/L)\,\text{Re}\,\text{Pr}\right]^{2/3}} = 3.66 + \frac{0.065\left(\frac{0.4\ \text{m}}{300\ \text{m}}\right)(77.19)(28{,}750)}{1+0.04\left[\left(\frac{0.4\ \text{m}}{300\ \text{m}}\right)(77.19)(28{,}750)\right]^{2/3}} = 24.47$$

and $$h = \frac{k}{D}Nu = \frac{0.146\ \text{W/m.°C}}{0.4\ \text{m}}(24.47) = 8.930\ \text{W/m}^2.\text{°C}$$

Next we determine the exit temperature of oil

$$A_s = \pi DL = \pi(0.4\ \text{m})(300\ \text{m}) = 377\ \text{m}^2$$

$$\dot m = \rho\dot V = \rho A_c \mathbf{V}_m = \rho\left(\frac{\pi D^2}{4}\right)\mathbf{V}_m = (893.5\ \text{kg/m}^3)\frac{\pi(0.4\ \text{m})^2}{4}(0.5\ \text{m/s}) = 56.14\ \text{kg/s}$$

$$T_e = T_s - (T_s - T_i)e^{-hA_s/(\dot m C_p)} = 0-(0-10)e^{-\frac{(8.930)(377)}{(56.14)(1838)}} = \mathbf{9.68\ °C}$$

(*b*) The logarithmic mean temperature difference and the rate of heat loss from the oil are

$$\Delta T_{\ln} = \frac{T_e - T_i}{\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)} = \frac{9.68-10}{\ln\left(\frac{0-9.68}{0-10}\right)} = 9.84\text{°C}$$

$$\dot Q = hA_s\Delta T_{\ln} = (8.930\ \text{W/m}^2.\text{°C})(377\ \text{m}^2)(9.84\text{°C}) = 3.31\times10^4\ \text{W} = \mathbf{3.31\ kW}$$

The friction factor is

$$f = \frac{64}{\text{Re}} = \frac{64}{77.19} = 0.8291$$

Then the pressure drop in the pipe and the required pumping power become

$$\Delta P = f\frac{L}{D}\frac{\rho\mathbf{V}_m^2}{2} = 0.8291\frac{300\ \text{m}}{0.4\ \text{m}}\frac{(893.5\ \text{kg/m}^3)(0.5\ \text{m/s})^2}{2}\left(\frac{1\ \text{kN}}{1000\ \text{kg}\cdot\text{m/s}}\right)\left(\frac{1\ \text{kPa}}{1\ \text{kN/m}^2}\right) = 69.54\ \text{kPa}$$

$$\dot W_{\text{pump,u}} = \dot V\Delta P = (0.0628\ \text{m}^3/\text{s})(69.54\ \text{kPa})\left(\frac{1\ \text{kW}}{1\ \text{kPa}\cdot\text{m}^3/\text{s}}\right) = \mathbf{4.364\ kW}$$

Discussion The power input determined is the mechanical power that needs to be imparted to the fluid. The shaft power will be much more than this due to pump inefficiency; the electrical power input will be even more due to motor inefficiency.

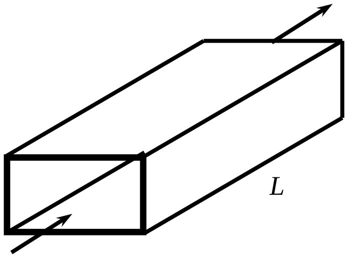
8-45 Laminar flow of a fluid through an isothermal square channel is considered. The change in the pressure drop and the rate of heat transfer are to be determined when the mean velocity is doubled.

Analysis The pressure drop of the fluid for laminar flow is expressed as

$$\Delta P_1 = f\frac{L}{D}\frac{\rho \mathbf{V}_m{}^2}{2} = \frac{64}{\text{Re}}\frac{L}{D}\frac{\rho \mathbf{V}_m{}^2}{2} = \frac{64\upsilon}{\mathbf{V}_m D}\frac{L}{D}\frac{\rho \mathbf{V}_m{}^2}{2} = 32\mathbf{V}_m\frac{\upsilon L\rho}{D^2}$$

When the free-stream velocity of the fluid is doubled, the pressure drop becomes

$$\Delta P_2 = f\frac{L}{D}\frac{\rho(2\mathbf{V}_m)^2}{2} = \frac{64}{\text{Re}}\frac{L}{D}\frac{\rho 4\mathbf{V}_m{}^2}{2} = \frac{64\upsilon}{2\mathbf{V}_m D}\frac{L}{D}\frac{\rho 4\mathbf{V}_m{}^2}{2} = 64\mathbf{V}_m\frac{\upsilon L\rho}{D^2}$$



Laminar flow
$\mathbf{V}_\text{m}$

Their ratio is

$$\frac{\Delta P_2}{\Delta P_1} = \frac{64}{32} = \mathbf{2}$$

The rate of heat transfer between the fluid and the walls of the channel is expressed as

$$\dot{Q}_1 = hA\Delta T_{\text{ln}} = \frac{k}{D}NuA\Delta T_{\text{ln}} = \frac{k}{D}1.86\left(\frac{\text{Re}\,\text{Pr}\,D}{L}\right)^{1/3}\left(\frac{\mu_b}{\mu_s}\right)^{0.4}A\Delta T_{\text{ln}}$$

$$= \frac{\mathbf{V}_m{}^{1/3}D^{1/3}}{\upsilon^{1/3}}\frac{k}{D}1.86\left(\frac{\text{Re}\,\text{Pr}\,D}{L}\right)^{1/3}\left(\frac{\mu_b}{\mu_s}\right)^{0.4}A\Delta T_{\text{ln}}$$

When the free-stream velocity of the fluid is doubled, the heat transfer rate becomes

$$\dot{Q}_2 = \frac{(2\mathbf{V}_m)^{1/3}D^{1/3}}{\upsilon^{1/3}}\frac{k}{D}1.86\left(\frac{\text{Re}\,\text{Pr}\,D}{L}\right)^{1/3}\left(\frac{\mu_b}{\mu_s}\right)^{0.4}A\Delta T_{\text{ln}}$$

Their ratio is

$$\frac{\dot{Q}_2}{\dot{Q}_1} = \frac{(2\mathbf{V}_m)^{1/3}}{\mathbf{V}_m{}^{1/3}} = 2^{1/3} = \mathbf{1.26}$$

Therefore, doubling the velocity will double the pressure drop but it will increase the heat transfer rate by only 26%.

8-46 Turbulent flow of a fluid through an isothermal square channel is considered. The change in the pressure drop and the rate of heat transfer are to be determined when the free-stream velocity is doubled.

Analysis The pressure drop of the fluid for turbulent flow is expressed as

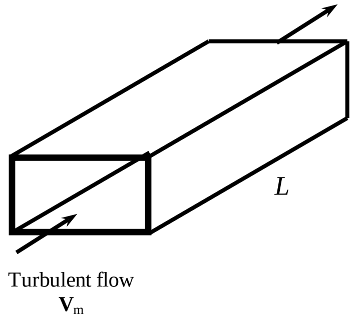
$$\Delta P_1 = f\,\frac{L}{D}\frac{\rho\mathbf{V}_m^{\;2}}{2} = 0.184\,\mathrm{Re}^{-0.2}\,\frac{L}{D}\frac{\rho\mathbf{V}_m^{\;2}}{2} = 0.184\,\frac{\mathbf{V}_m^{\;-0.2}D^{-0.2}}{\upsilon^{-0.2}}\,\frac{L}{D}\frac{\rho\mathbf{V}_m^{\;2}}{2}$$

$$= 0.092\mathbf{V}_m^{\;1.8}\left(\frac{D}{\upsilon}\right)^{-0.2}\frac{L\rho}{D}$$

When the free-stream velocity of the fluid is doubled, the pressure drop becomes

$$\Delta P_2 = f\,\frac{L}{D}\frac{\rho(2\mathbf{V}_m)^2}{2} = 0.184\,\mathrm{Re}^{-0.2}\,\frac{L}{D}\frac{\rho4\mathbf{V}_m^{\;2}}{2} = 0.184\,\frac{\mathbf{(2V}_m\mathbf{)}^{-0.2}D^{-0.2}}{\upsilon^{-0.2}}\,\frac{L}{D}\frac{\rho4\mathbf{V}_m^{\;2}}{2}$$

$$= 0.368(2)^{-0.2}\mathbf{V}_m^{\;1.8}\left(\frac{D}{\upsilon}\right)^{-0.2}\frac{L\rho}{D}$$



Their ratio is

$$\frac{\Delta P_2}{\Delta P_1} = \frac{0.368(2)^{-0.2}\mathbf{V}_m^{\;1.8}}{0.092V_m^{\;1.8}} = 4(2)^{-0.2} = \mathbf{3.48}$$

The rate of heat transfer between the fluid and the walls of the channel is expressed as

$$\dot{Q}_1 = hA\Delta T_{\ln} = \frac{k}{D}NuA\Delta T_{\ln} = \frac{k}{D}0.023\,\mathrm{Re}^{0.8}\,\mathrm{Pr}^{1/3}\,A\Delta T_{\ln}$$

$$= 0.023\mathbf{V}_m^{\;0.8}\left(\frac{D}{\upsilon}\right)^{0.8}\frac{k}{D}\mathrm{Pr}^{1/3}\,A\Delta T_{\ln}$$

When the free-stream velocity of the fluid is doubled, the heat transfer rate becomes

$$\dot{Q}_2 = 0.023(2\mathbf{V}_m)^{0.8}\left(\frac{D}{\upsilon}\right)^{0.8}\frac{k}{D}\mathrm{Pr}^{1/3}\,A\Delta T_{\ln}$$

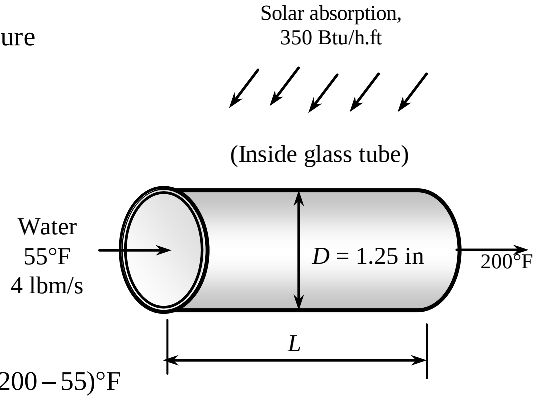
Their ratio is

$$\frac{\dot{Q}_2}{\dot{Q}_1} = \frac{(2\mathbf{V}_m)^{0.8}}{\mathbf{V}_m^{\;0.8}} = 2^{0.8} = \mathbf{1.74}$$

Therefore, doubling the velocity will increase the pressure drop 3.8 times but it will increase the heat transfer rate by only 74%.

8-47E Water is heated in a parabolic solar collector. The required length of parabolic collector and the surface temperature of the collector tube are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The thermal resistance of the tube is negligible. **3** The inner surfaces of the tube are smooth.



Properties The properties of water at the average temperature of (55+200)/2 = 127.5°F are (Table A-9E)

$$\rho = 61.59\ \text{lbm/ft}^3$$
$$k = 0.374\ \text{Btu/ft.°F}$$
$$\upsilon = \mu/\rho = 0.5683\times10^{-5}\ \text{ft}^2\text{/s}$$
$$C_p = 0.999\text{Btu/lbm.°F}$$
$$\text{Pr} = 3.368$$

Analysis The total rate of heat transfer is

$$\dot{Q} = \dot{m}C_p(T_e - T_i) = (4\ \text{lbm/s})(0.999\ \text{Btu/lbm.°F})(200-55)\text{°F}$$
$$= 579.4\ \text{Btu/s} = 2.086\times10^6\ \text{Btu/h}$$

The length of the tube required is

$$L = \frac{\dot{Q}_{total}}{\dot{Q}} = \frac{2.086\times10^4\ \text{Btu/h}}{350\ \text{Btu/h.ft}} = \mathbf{5960\ ft}$$

The velocity of water and the Reynolds number are

$$\mathbf{V}_m = \frac{\dot{m}}{\rho A_c} = \frac{4\ \text{lbm/s}}{(61.59\ \text{lbm/m}^3)\pi\frac{(1.25/12\ \text{ft})^2}{4}} = 7.621\ \text{ft/s}$$

$$\text{Re} = \frac{\mathbf{V}_m D_h}{\upsilon} = \frac{(7.621\ \text{m/s})(1.25/12\ \text{ft})}{0.5683\times10^{-5}\ \text{ft}^2\text{/s}} = 1.397\times10^5$$

which is greater than 10,000. Therefore, we can assume fully developed turbulent flow in the entire tube, and determine the Nusselt number from

$$Nu = \frac{hD_h}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.4} = 0.023(1.397\times10^4)^{0.8}(3.368)^{0.4} = 488.4$$

The heat transfer coefficient is

$$h = \frac{k}{D_h}Nu = \frac{0.374\ \text{Btu/h.ft.°F}}{1.25/12\ \text{ft}}(488.4) = 1754\ \text{Btu/h.ft}^2\text{.°F}$$

The heat flux on the tube is

$$\dot{q} = \frac{\dot{Q}}{A_s} = \frac{2.086\times10^4\ \text{Btu/h}}{\pi(1.25/12\ \text{ft})(5960\ \text{ft})} = 1070\ \text{Btu/h.ft}^2$$

Then the surface temperature of the tube at the exit becomes

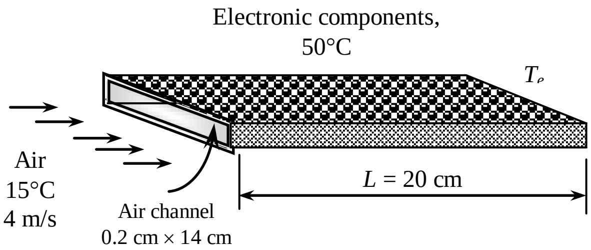
$$\dot{q} = h(T_s - T_e) \longrightarrow T_s = T_e + \frac{\dot{q}}{h} = 200\text{°F} + \frac{1070\ \text{Btu/h.ft}^2}{1754\ \text{Btu/h.ft}^2\text{.°F}} = \mathbf{200.6°F}$$

8-48 A circuit board is cooled by passing cool air through a channel drilled into the board. The maximum total power of the electronic components is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat flux at the top surface of the channel is uniform, and heat transfer through other surfaces is negligible. **3** The inner surfaces of the channel are smooth. **4** Air is an ideal gas with constant properties. **5** The pressure of air in the channel is 1 atm.

Properties The properties of air at 1 atm and estimated average temperature of 25°C are (Table A-15)

$$\rho = 1.184 \text{ kg/m}^3$$
$$k = 0.02551 \text{ W/m.°C}$$
$$\upsilon = 1.562\times10^{-5} \text{ m}^2\text{/s}$$
$$C_p = 1007 \text{ J/kg.°C}$$
$$\Pr = 0.7296$$



Analysis The cross-sectional and heat transfer surface areas are

$$A_c = (0.002 \text{ m})(0.14 \text{ m}) = 0.00028 \text{ m}^2$$
$$A_s = (0.14 \text{ m})(0.2 \text{ m}) = 0.028 \text{ m}^2$$

To determine heat transfer coefficient, we first need to find the Reynolds number,

$$D_h = \frac{4A_c}{P} = \frac{4(0.00028 \text{ m}^2)}{2(0.002 \text{ m} + 0.14 \text{ m})} = 0.003944 \text{ m}$$

$$\text{Re} = \frac{\mathbf{V}_m D_h}{\upsilon} = \frac{(4 \text{ m/s})(0.003944 \text{ m})}{1.562\times10^{-5} \text{ m}^2\text{/s}} = 1010$$

which is less than 2300. Therefore, the flow is laminar and the thermal entry length is

$$L_t = 0.05 \text{Re} \Pr D_h = 0.05(1010)(0.7296)(0.003944 \text{ m}) = 0.1453 \text{ m} < 0.20 \text{ m}$$

Therefore, we have developing flow through most of the channel. However, we take the conservative approach and assume fully developed flow, and from Table 8-1 we read Nu = 8.24. Then the heat transfer coefficient becomes

$$h = \frac{k}{D_h} Nu = \frac{0.02551 \text{ W/m.°C}}{0.003944 \text{ m}}(8.24) = 53.30 \text{ W/m}^2\text{.°C}$$

Also,

$$\dot{m} = \rho \mathbf{V} A_c = (1.184 \text{ kg/m}^3)(4 \text{ m/s})(0.00028 \text{ m}^2) = 0.001326 \text{ kg/s}$$

Heat flux at the exit can be written as $\dot{q} = h(T_s - T_e)$ where $T_s = 50°\text{C}$ at the exit. Then the heat transfer rate can be expressed as $\dot{Q} = \dot{q}A_s = hA_s(T_s - T_e)$, and the exit temperature of the air can be determined from

$$hA_s(T_s - T_e) = \dot{m}C_p(T_e - T_i)$$
$$(53.30 \text{ W/m}^2\text{.°C})(0.028 \text{ m}^2)(50°\text{C} - T_e) = (0.001326 \text{ kg/s})(1007 \text{ J/kg.°C})(T_e - 15°\text{C})$$
$$T_e = 33.5°\text{C}$$

Then the maximum total power of the electronic components that can safely be mounted on this circuit board becomes

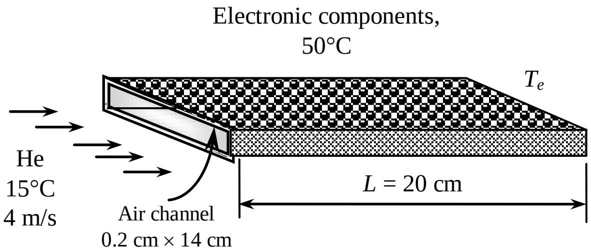
$$\dot{Q}_{\max} = \dot{m}C_p(T_e - T_i) = (0.001326 \text{ kg/s})(1007 \text{ J/kg.°C})(33.5 - 15°\text{C}) = \mathbf{24.7\ W}$$

8-49 A circuit board is cooled by passing cool helium gas through a channel drilled into the board. The maximum total power of the electronic components is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat flux at the top surface of the channel is uniform, and heat transfer through other surfaces is negligible. **3** The inner surfaces of the channel are smooth. **4** Helium is an ideal gas. **5** The pressure of helium in the channel is 1 atm.

Properties The properties of helium at the estimated average temperature of 25°C are (Table A-16)

$$\rho = 0.1635 \text{ kg/m}^3$$
$$k = 0.1565 \text{ W/m.°C}$$
$$\upsilon = 1.233\times10^{-4} \text{ m}^2\text{/s}$$
$$C_p = 5193 \text{ J/kg.°C}$$
$$\text{Pr} = 0.669$$



Analysis The cross-sectional and heat transfer surface areas are

$$A_c = (0.002 \text{ m})(0.14 \text{ m}) = 0.00028 \text{ m}^2$$
$$A_s = (0.14 \text{ m})(0.2 \text{ m}) = 0.028 \text{ m}^2$$

To determine heat transfer coefficient, we need to first find the Reynolds number

$$D_h = \frac{4A_c}{P} = \frac{4(0.00028 \text{ m}^2)}{2(0.002 \text{ m} + 0.14 \text{ m})} = 0.003944 \text{ m}$$

$$\text{Re} = \frac{\mathbf{V}_m D_h}{\upsilon} = \frac{(4 \text{ m/s})(0.003944 \text{ m})}{1.233\times10^{-4} \text{ m}^2\text{/s}} = 127.9$$

which is less than 2300. Therefore, the flow is laminar and the thermal entry length is

$$L_t = 0.05 \,\text{Re}\,\text{Pr}\, D_h = 0.05(127.9)(0.669)(0.003944 \text{ m}) = 0.01687 \text{ m} << 0.20 \text{ m}$$

Therefore, the flow is fully developed flow, and from Table 8-3 we read Nu = 8.24. Then the heat transfer coefficient becomes

$$h = \frac{k}{D_h} Nu = \frac{0.1565 \text{ W/m.°C}}{0.003944 \text{ m}}(8.24) = 327.0 \text{ W/m}^2\text{.°C}$$

Also,

$$\dot{m} = \rho \mathbf{V} A_c = (0.1635 \text{ kg/m}^3)(4 \text{ m/s})(0.00028 \text{ m}^2) = 0.0001831 \text{ kg/s}$$

Heat flux at the exit can be written as $\dot{q} = h(T_s - T_e)$ where $T_s = 50°\text{C}$ at the exit. Then the heat transfer rate can be expressed as $\dot{Q} = \dot{q}A_s = hA_s(T_s - T_e)$, and the exit temperature of the air can be determined from

$$\dot{m}C_p(T_e - T_i) = hA_s(T_s - T_e)$$
$$(0.0001831 \text{ kg/s})(5193 \text{ J/kg.°C})(T_e - 15°\text{C}) = (327.0 \text{ W/m}^2\text{.°C})(0.0568 \text{ m}^2)(50°\text{C} - T_e)$$
$$T_e = 46.7°\text{C}$$

Then the maximum total power of the electronic components that can safely be mounted on this circuit board becomes

$$\dot{Q}_{\max} = \dot{m}C_p(T_e - T_i) = (0.0001831 \text{ kg/s})(5193 \text{ J/kg.°C})(46.7 - 15°\text{C}) = \mathbf{30.2 \text{ W}}$$

8-51 Air enters a rectangular duct. The exit temperature of the air, the rate of heat transfer, and the fan power are to be determined.

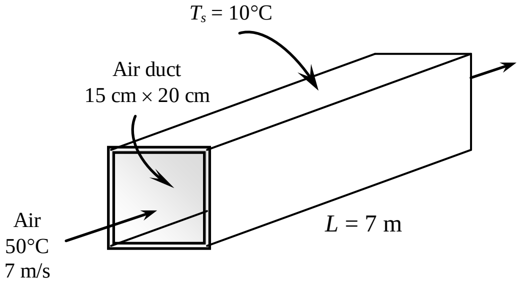
Assumptions **1** Steady operating conditions exist. **2** The inner surfaces of the duct are smooth. **3** Air is an ideal gas with constant properties. **4** The pressure of air in the duct is 1 atm.

Properties We assume the bulk mean temperature for air to be 40°C since the mean temperature of air at the inlet will drop somewhat as a result of heat loss through the duct whose surface is at a lower temperature. The properties of air at this temperature and 1 atm are (Table A-15)

$$\rho = 1.127 \text{ kg/m}^3 \qquad C_p = 1007 \text{ J/kg.°C}$$

$$k = 0.02662 \text{ W/m.°C} \qquad \text{Pr} = 0.7255$$

$$\upsilon = 1.702\times10^{-5} \text{ m}^2/\text{s}$$



Analysis (*a*) The hydraulic diameter, the mean velocity of air, and the Reynolds number are

$$D_h = \frac{4A_c}{P} = \frac{4(0.15 \text{ m})(0.20 \text{ m})}{2\left[(0.15 \text{ m}) + (0.20 \text{ m})\right]} = 0.1714 \text{ m}$$

$$\text{Re} = \frac{\mathbf{V}_m D_h}{\upsilon} = \frac{(7 \text{ m/s})(0.1714 \text{ m})}{1.702\times10^{-5} \text{ m}^2/\text{s}} = 70{,}525$$

which is greater than 10,000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D_h = 10(0.1714 \text{ m}) = 1.714 \text{ m}$$

which is much shorter than the total length of the duct. Therefore, we can assume fully developed turbulent flow in the entire duct, and determine the Nusselt number from

$$Nu = \frac{hD_h}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.3} = 0.023(70{,}525)^{0.8}(0.7255)^{0.3} = 158.0$$

Heat transfer coefficient is

$$h = \frac{k}{D_h} Nu = \frac{0.02662 \text{ W/m.°C}}{0.1714 \text{ m}}(158.0) = 24.53 \text{ W/m}^2\text{.°C}$$

Next we determine the exit temperature of air

$$A_s = 2\times7[(0.15 \text{ m}) + (0.20 \text{ m})] = 4.9 \text{ m}^2$$

$$A_c = (0.15 \text{ m})(0.20 \text{ m}) = 0.03 \text{ m}^2$$

$$\dot{m} = \rho V A_c = (1.127 \text{ kg/m}^3)(7 \text{ m/s})(0.03 \text{ m}^2) = 0.2367 \text{ kg/s}$$

$$T_e = T_s - (T_s - T_i)e^{-hA_s/(\dot{m}C_p)} = 10 - (10-50)e^{-\frac{(24.53)(4.9)}{(0.2367)(1007)}} = \mathbf{34.2°C}$$

(*b*) The logarithmic mean temperature difference and the rate of heat loss from the air are

$$\Delta T_{\ln} = \frac{T_e - T_i}{\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)} = \frac{34.2 - 50}{\ln\left(\frac{10 - 34.2}{10 - 50}\right)} = 31.42\text{°C}$$

$$\dot{Q} = hA_s\Delta T_{\ln} = (24.53 \text{ W/m}^2\text{.°C})(4.9 \text{ m}^2)(31.42\text{°C}) = \mathbf{3776 \text{ W}}$$

(*c*) The friction factor, the pressure drop, and then the fan power can be determined for the case of fully developed turbulent flow to be

$$f = 0.184\,\text{Re}^{-0.2} = 0.184(70{,}525)^{-0.2} = 0.01973$$

$$\Delta P = f\,\frac{L}{D}\frac{\rho \mathbf{V}_m^{\,2}}{2} = 0.01973\frac{(7 \text{ m})}{(0.1714 \text{ m})}\frac{(1.127 \text{ kg/m}^3)(7 \text{ m/s})^2}{2} = 22.25 \text{ N/m}^2$$

$$\dot{W}_{pump} = \frac{\dot{m}\Delta P}{\rho} = \frac{(0.2367 \text{ kg/s})(22.25 \text{ N/m}^2)}{1.127 \text{ kg/m}^3} = \mathbf{4.67 \text{ W}}$$

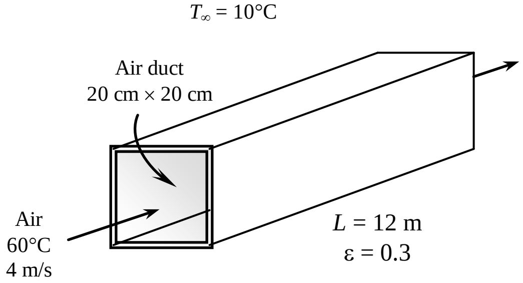
8-53 Hot air enters a sheet metal duct located in a basement. The exit temperature of hot air and the rate of heat loss are to be determined.

Assumptions **1** Steady flow conditions exist. **2** The inner surfaces of the duct are smooth. **3** The thermal resistance of the duct is negligible. **4** Air is an ideal gas with constant properties. **5** The pressure of air is 1 atm.

Properties We expect the air temperature to drop somewhat, and evaluate the air properties at 1 atm and the estimated bulk mean temperature of 50°C (Table A-15),

$$\rho = 1.092 \text{ kg/m}^3; \qquad k = 0.02735 \text{ W/m.°C}$$
$$\upsilon = 1.797\times10^{-5} \text{ m}^2\text{/s}; \quad C_p = 1007 \text{ J/kg.°C}$$
$$\Pr = 0.7228$$



Analysis The surface area and the Reynolds number are

$$A_s = 4aL = 4\times(0.2\text{ m})(12\text{ m}) = 9.6\text{ m}$$

$$D_h = \frac{4A_c}{p} = \frac{4a^2}{4a} = a = 0.2\text{ m}$$

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(4\text{ m/s})(0.20\text{ m})}{1.797\times10^{-5}\text{ m}^2\text{/s}} = 44{,}509$$

which is greater than 10,000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D_h = 10(0.2\text{ m}) = 2.0\text{ m}$$

which is much shorter than the total length of the duct. Therefore, we can assume fully developed turbulent flow for the entire duct, and determine the Nusselt number from

$$Nu = \frac{hD_h}{k} = 0.023\text{Re}^{0.8}\Pr^{0.3} = 0.023(44{,}509)^{0.8}(0.7228)^{0.3} = 109.2$$

and

$$h = \frac{k}{D_h}Nu = \frac{0.02735\text{ W/m.°C}}{0.2\text{ m}}(109.2) = 14.93\text{ W/m}^2\text{.°C}$$

The mass flow rate of air is

$$\dot{m} = \rho A_c V = (1.092\text{ kg/m}^3)(0.2\times0.2)\text{m}^2(4\text{ m/s}) = 0.1748\text{ kg/s}$$

In steady operation, heat transfer from hot air to the duct must be equal to the heat transfer from the duct to the surrounding (by convection and radiation), which must be equal to the energy loss of the hot air in the duct. That is,

$$\dot{Q} = \dot{Q}_{\text{conv,in}} = \dot{Q}_{\text{conv+rad,out}} = \Delta\dot{E}_{\text{hot air}}$$

Assuming the duct to be at an average temperature of T_s , the quantities above can be expressed as

$\dot{Q}_{\text{conv,in}}$: $$\dot{Q} = h_i A_s \Delta T_{\ln} = h_i A_s \frac{T_e - T_i}{\ln\left(\dfrac{T_s - T_e}{T_s - T_i}\right)} \rightarrow \dot{Q} = (14.93\text{ W/m}^2\text{.°C})(9.6\text{ m}^2)\frac{T_e - 60}{\ln\left(\dfrac{T_s - T_e}{T_s - 60}\right)}$$

$\dot{Q}_{\text{conv+rad,out}}$: $$\dot{Q} = h_o A_s(T_s - T_o) + \varepsilon A_s\sigma\left(T_s^4 - T_o^4\right) \rightarrow \dot{Q} = (10\text{ W/m}^2\text{.°C})(9.6\text{ m}^2)(T_s - 10)\text{°C}$$
$$+ 0.3(9.6\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2.K^4)\left[(T_s + 273)^4 - (10 + 273)^4\right]K^4$$

$\Delta\dot{E}_{\text{hot air}}$: $$\dot{Q} = \dot{m}C_p(T_e - T_i) \rightarrow \dot{Q} = (0.1748\text{ kg/s})(1007\text{ J/kg.°C})(60 - T_e)\text{°C}$$

This is a system of three equations with three unknowns whose solution is

$$\dot{Q} = \mathbf{2622\text{ W}},\ T_e = \mathbf{45.1°C},\text{ and } T_s = 33.3\text{°C}$$

Therefore, the hot air will lose heat at a rate of 2622 W and exit the duct at 45.1°C.

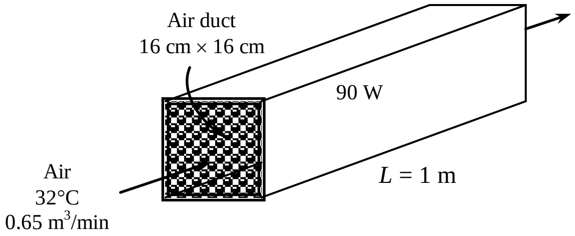
8-55 The components of an electronic system located in a rectangular horizontal duct are cooled by forced air. The exit temperature of the air and the highest component surface temperature are to be determined.

Assumptions **1** Steady flow conditions exist. **2** The inner surfaces of the duct are smooth. **3** The thermal resistance of the duct is negligible. **4** Air is an ideal gas with constant properties. **5** The pressure of air is 1 atm.

Properties We assume the bulk mean temperature for air to be 35°C since the mean temperature of air at the inlet will rise somewhat as a result of heat gain through the duct whose surface is exposed to a constant heat flux. The properties of air at 1 atm and this temperature are (Table A-15)

$$\begin{aligned}\rho &= 1.146\ \text{kg/m}^3\\ k &= 0.02625\ \text{W/m.°C}\\ \upsilon &= 1.654\times10^{-5}\ \text{m}^2/\text{s}\\ C_p &= 1007\ \text{J/kg.°C}\\ \Pr &= 0.7268\end{aligned}$$



Analysis (*a*) The mass flow rate of air and the exit temperature are determined from

$$\dot m = \rho\dot V = (1.146\ \text{kg/m}^3)(0.65\ \text{m}^3/\text{min}) = 0.7449\ \text{kg/min} = 0.01241\ \text{kg/s}$$

$$\dot Q = \dot m C_p(T_e - T_i) \rightarrow T_e = T_i + \frac{\dot Q}{\dot m C_p} = 32°\text{C} + \frac{(0.85)(90\ \text{W})}{(0.01241\ \text{kg/s})(1007\ \text{J/kg.°C})} = \mathbf{38.1°C}$$

(*b*) The mean fluid velocity and hydraulic diameter are

$$V_m = \frac{\dot V}{A_c} = \frac{0.65\ \text{m/min}}{(0.16\ \text{m})(0.16\ \text{m})} = 25.4\ \text{m/min} = 0.4232\ \text{m/s}$$

$$D_h = \frac{4A_c}{P} = \frac{4(0.16\ \text{m})(0.16\ \text{m})}{4(0.16\ \text{m})} = 0.16\ \text{m}$$

Then

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(0.4232\ \text{m/s})(0.16\ \text{m})}{1.654\times10^{-5}\ \text{m}^2/\text{s}} = 4093$$

which is greater than 10,000. Also, the components will cause turbulence and thus we can assume fully developed turbulent flow in the entire duct, and determine the Nusselt number from

$$Nu = \frac{hD_h}{k} = 0.023\,\text{Re}^{0.8}\,\Pr^{0.4} = 0.023(4093)^{0.8}(0.7268)^{0.4} = 15.70$$

and

$$h = \frac{k}{D_h}Nu = \frac{0.02625\ \text{W/m.°C}}{0.16\ \text{m}}(15.70) = 2.576\ \text{W/m}^2.°\text{C}$$

The highest component surface temperature will occur at the exit of the duct. Assuming uniform surface heat flux, its value is determined from

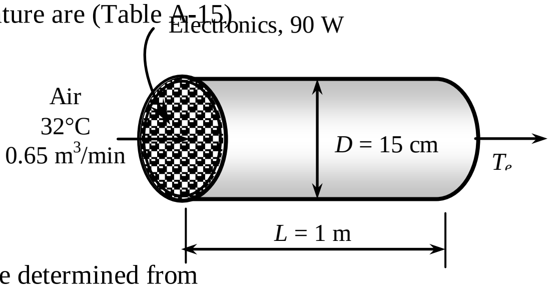
$$\dot Q/A_s = h(T_{s,highest} - T_e) \rightarrow T_{s,highest} = T_e + \frac{\dot Q/A_s}{h} = 38.1°\text{C} + \frac{(0.85)(90\ \text{W})/[4(0.16\ \text{m})(1\ \text{m})]}{(2.576\ \text{W/m}^2.°\text{C})} = \mathbf{84.5°C}$$

8-56 The components of an electronic system located in a circular horizontal duct are cooled by forced air. The exit temperature of the air and the highest component surface temperature are to be determined.

Assumptions **1** Steady flow conditions exist. **2** The inner surfaces of the duct are smooth. **3** The thermal resistance of the duct is negligible. **4** Air is an ideal gas with constant properties. **5** The pressure of air is 1 atm.

Properties We assume the bulk mean temperature for air to be 310 K since the mean temperature of air at the inlet will rise somewhat as a result of heat gain through the duct whose surface is exposed to a constant heat flux. The properties of air at 1 atm and this temperature are (Table A-15)

$$\rho = 1.143 \text{ kg/m}^3$$
$$k = 0.0268 \text{ W/m.°C}$$
$$\upsilon = 1.67 \times 10^{-5} \text{ m}^2/\text{s}$$
$$C_p = 1006 \text{ J/kg.°C}$$
$$\Pr = 0.710$$



Analysis (a) The mass flow rate of air and the exit temperature are determined from

$$\dot{m} = \rho\dot{V} = (1.143 \text{ kg/m}^3)(0.65 \text{ m}^3/\text{min}) = 0.74295 \text{ kg/min} = 0.0124 \text{ kg/s}$$

$$\dot{Q} = \dot{m}C_p(T_e - T_i) \rightarrow T_e = T_i + \frac{\dot{Q}}{\dot{m}C_p} = 32\text{ °C} + \frac{(0.85)(90 \text{ W})}{(0.0124 \text{ kg/s})(1006 \text{ J/kg.°C})} = \mathbf{38.1\ °C}$$

(b) The mean fluid velocity is

$$V_m = \frac{\dot{V}}{A_c} = \frac{0.65 \text{ m/min}}{\pi(0.15 \text{ m})^2/4} = 36.7 \text{ m/min} = 0.612 \text{ m/s}$$

Then,

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(0.612 \text{ m/s})(0.15 \text{ m})}{1.67 \times 10^{-5} \text{ m}^2/\text{s}} = 5497$$

which is greater than 4000. Also, the components will cause turbulence and thus we can assume fully developed turbulent flow in the entire duct, and determine the Nusselt number from

$$Nu = \frac{hD_h}{k} = 0.023\text{Re}^{0.8}\Pr^{0.4} = 0.023(5497)^{0.8}(0.710)^{0.4} = 19.7$$

and

$$h = \frac{k}{D_h}Nu = \frac{0.0268 \text{ W/m.°C}}{0.15 \text{ m}}(19.7) = 3.52 \text{ W/m}^2\text{.°C}$$

The highest component surface temperature will occur at the exit of the duct. Assuming uniform heat flux, its value is determined from

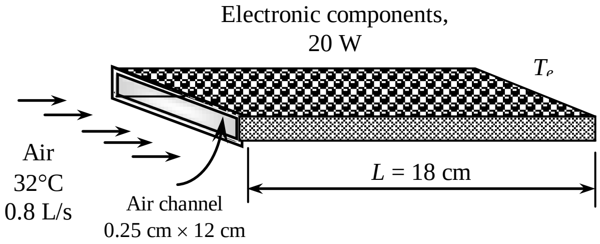
$$\dot{q} = h(T_{s,highest} - T_e) \rightarrow T_{s,highest} = T_e + \frac{\dot{q}}{h} = 38.1\text{°C} + \frac{(0.85)(90 \text{ W})/\left[\pi(0.15 \text{ m})(1 \text{ m})\right]}{(3.52 \text{ W/m}^2\text{.°C})} = \mathbf{84.2°C}$$

8-57 Air enters a hollow-core printed circuit board. The exit temperature of the air and the highest temperature on the inner surface are to be determined. √

Assumptions **1** Steady flow conditions exist. **2** Heat generated is uniformly distributed over the two surfaces of the PCB. **3** Air is an ideal gas with constant properties. **4** The pressure of air is 1 atm.

Properties We assume the bulk mean temperature for air to be 310 K since the mean temperature of air at the inlet will rise somewhat as a result of heat gain through the hollow core whose surface is exposed to a constant heat flux. The properties of air at 1 atm and this temperature are (Table A-15)

$$\rho = 1.143\ \text{kg/m}^3$$
$$k = 0.0268\ \text{W/m.°C}$$
$$\upsilon = 1.67\times10^{-5}\ \text{m}^2\text{/s}$$
$$C_p = 1006\ \text{J/kg.°C}$$
$$\text{Pr} = 0.710$$
$$\mu_b = 1.89\times10^{-5}\ \text{kg/m.s}$$
$$\mu_{s,@\,350\ \text{K}} = 2.08\times10^{-5}\ \text{kg/m.s}$$



Analysis (a) The mass flow rate of air and the exit temperature are determined from

$$\dot{m} = \rho\dot{V} = (1.143\ \text{kg/m}^3)(0.8\times10^{-3}\ \text{m}^3\text{/s}) = 9.14\times10^{-4}\ \text{kg/s}$$

$$\dot{Q} = \dot{m}C_p(T_e - T_i) \rightarrow T_e = T_i + \frac{\dot{Q}}{\dot{m}C_p} = 32\ \text{°C} + \frac{20\ \text{W}}{(9.14\times10^{-4}\ \text{kg/s})(1006\ \text{J/kg.°C})} = \mathbf{53.7°C}$$

(b) The mean fluid velocity and hydraulic diameter are

$$V_m = \frac{\dot{V}}{A_c} = \frac{0.8\times10^{-3}\ \text{m}^3\text{/s}}{(0.12\ \text{m})(0.0025\ \text{m})} = 2.67\ \text{m/s}$$

$$D_h = \frac{4A_c}{P} = \frac{4(0.12\ \text{m})(0.0025\ \text{m})}{2[(0.12\ \text{m}) + (0.0025\ \text{m})]} = 0.0049\ \text{m}$$

Then,

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(2.67\ \text{m/s})(0.0049\ \text{m})}{1.67\times10^{-5}\ \text{m}^2\text{/s}} = 783$$

which is less than 2300. Therefore, the flow is laminar and the thermal entry length in this case is

$$L_t = 0.05\,\text{Re}\,\text{Pr}\,D_h = 0.05(783)(0.71)(0.0049\ \text{m}) = 0.14\ \text{m}$$

which is shorter than the total length of the duct. Therefore, we assume thermally developing flow , and determine the Nusselt number from

$$Nu = \frac{hD_h}{k} = 1.86\left(\frac{\text{Re}\,\text{Pr}\,D}{L}\right)^{1/3}\left(\frac{\mu_b}{\mu_s}\right)^{0.14} = 1.86\left[\frac{(783)(0.71)(0.0049)}{0.18}\right]^{1/3}\left(\frac{1.89\times10^{-5}}{2.08\times10^{-5}}\right)^{0.14} = 8.24$$

and,

$$h = \frac{k}{D_h}Nu = \frac{0.0268\ \text{W/m.°C}}{0.0049\ \text{m}}(8.24) = 46.2\ \text{W/m}^2\text{.°C}$$

The highest component surface temperature will occur at the exit of the duct. Its value is determined from

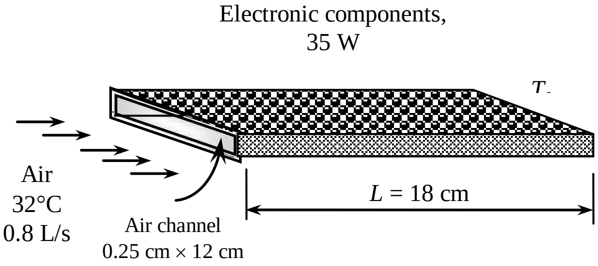
$$\dot{Q} = hA_s(T_{s,highest} - T_e) \rightarrow T_{s,highest} = T_e + \frac{\dot{Q}}{hA_s}$$
$$= 53.7\text{°C} + \frac{20\ \text{W}}{(46.2\ \text{W/m}^2\text{.°C})\left[2(0.12\times0.18 + 0.0025\times0.18)\text{m}^2\right]} = \mathbf{64.0°C}$$

8-58 Air enters a hollow-core printed circuit board. The exit temperature of the air and the highest temperature on the inner surface are to be determined.

Assumptions **1** Steady flow conditions exist. **2** Heat generated is uniformly distributed over the two surfaces of the PCB. **3** Air is an ideal gas with constant properties. **4** The pressure of air is 1 atm.

Properties We assume the bulk mean temperature for air to be 310 K since the mean temperature of air at the inlet will rise somewhat as a result of heat gain through the hollow core whose surface is exposed to a constant heat flux. The properties of air at 1 atm and this temperature are (Table A-15)

$$\rho = 1.143 \text{ kg/m}^3$$
$$k = 0.0268 \text{ W/m.°C}$$
$$\upsilon = 1.67 \times 10^{-5} \text{ m}^2\text{/s}$$
$$C_p = 1006 \text{ J/kg.°C}$$
$$\Pr = 0.710$$
$$\mu_b = 1.89 \times 10^{-5} \text{ kg/m.s}$$
$$\mu_{s,@350\text{ K}} = 2.08 \times 10^{-5} \text{ kg/m.s}$$



Analysis (a) The mass flow rate of air and the exit temperature are determined from

$$\dot{m} = \rho\dot{V} = (1.143 \text{ kg/m}^3)(0.8 \times 10^{-3} \text{ m}^3\text{/s}) = 9.14 \times 10^{-4} \text{ kg/s}$$

$$\dot{Q} = \dot{m}C_p(T_e - T_i) \rightarrow T_e = T_i + \frac{\dot{Q}}{\dot{m}C_p} = 32°\text{C} + \frac{35 \text{ W}}{(9.14 \times 10^{-4} \text{ kg/s})(1006 \text{ J/kg.°C})} = \mathbf{70.1°C}$$

(b) The mean fluid velocity and hydraulic diameter are

$$V_m = \frac{\dot{V}}{A_c} = \frac{0.8 \times 10^{-3} \text{ m}^3\text{/s}}{(0.12 \text{ m})(0.0025 \text{ m})} = 2.67 \text{ m/s}$$

$$D_h = \frac{4A_c}{P} = \frac{4(0.12 \text{ m})(0.0025 \text{ m})}{2[(0.12 \text{ m}) + (0.0025 \text{ m})]} = 0.0049 \text{ m}$$

Then,

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(2.67 \text{ m/s})(0.0049 \text{ m})}{1.67 \times 10^{-5} \text{ m}^2\text{/s}} = 783$$

which is less than 2300. Therefore, the flow is laminar and the thermal entry length in this case is

$$L_t = 0.05 \text{Re} \Pr D_h = 0.05(783)(0.71)(0.0049 \text{ m}) = 0.14 \text{ m}$$

which is shorter than the total length of the duct. Therefore, we assume thermally developing flow , and determine the Nusselt number from

$$Nu = \frac{hD_h}{k} = 1.86\left(\frac{\text{Re} \Pr D}{L}\right)^{1/3}\left(\frac{\mu_b}{\mu_s}\right)^{0.14} = 1.86\left[\frac{(783)(0.71)(0.0049)}{0.18}\right]^{1/3}\left(\frac{1.89 \times 10^{-5}}{2.08 \times 10^{-5}}\right)^{0.14} = 4.54$$

and,

$$h = \frac{k}{D_h}Nu = \frac{0.0268 \text{ W/m.°C}}{0.0049 \text{ m}}(4.54) = 24.8 \text{ W/m}^2\text{.°C}$$

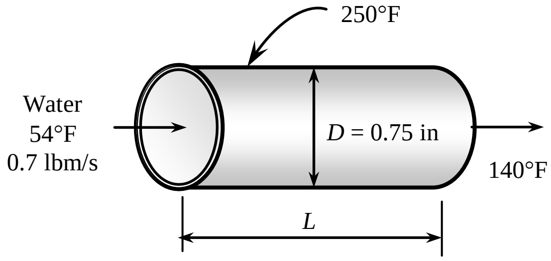
The highest component surface temperature will occur at the exit of the duct. Its value is determined from

$$\dot{Q} = hA_s(T_{s,highest} - T_e) \longrightarrow T_{s,highest} = T_e + \frac{\dot{Q}}{hA_s}$$
$$= 70.1°\text{C} + \frac{35 \text{ W}}{(24.8 \text{ W/m}^2\text{.°C})[2(0.12 \times 0.18 + 0.0025 \times 0.18)\text{m}^2]} = \mathbf{102.1°C}$$

8-59E Water is heated by passing it through thin-walled copper tubes. The length of the copper tube that needs to be used is to be determined. √

Assumptions **1** Steady flow conditions exist. **2** The inner surfaces of the tube are smooth. **3** The thermal resistance of the tube is negligible. **4** The temperature at the tube surface is constant.

Properties The properties of water at the bulk mean fluid temperature of $T_{b,ave} = (54+140)/2 = 97°\text{F} \approx 100°\text{F}$ are (Table A-9E)



$$\rho = 62.0 \text{ lbm/ft}^3$$
$$k = 0.363 \text{ Btu/h.ft.°F}$$
$$\upsilon = 0.738\times10^{-5} \text{ ft}^2\text{/s}$$
$$C_p = 0.999 \text{ Btu/lbm.°F}$$
$$\text{Pr} = 4.54$$

Analysis (*a*) The mass flow rate and the Reynolds number are

$$\dot{m} = \rho A_c V_m \rightarrow V_m = \frac{\dot{m}}{\rho A_c} = \frac{0.7 \text{ lbm/s}}{(62 \text{ lbm/ft}^3)[\pi(0.75/12 \text{ ft})^2/4]} = 3.68 \text{ ft/s}$$

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(3.68 \text{ ft/s})(0.75/12 \text{ ft})}{0.738\times10^{-5} \text{ ft}^2\text{/s}} = 31{,}165$$

which is greater than 4000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D = 10(0.75 \text{ in}) = 7.5 \text{ in}$$

which is probably shorter than the total length of the pipe we will determine. Therefore, we can assume fully developed turbulent flow in the entire duct, and determine the Nusselt number from

$$Nu = \frac{hD_h}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.4} = 0.023(31{,}165)^{0.8}(4.54)^{0.4} = 165.8$$

and

$$h = \frac{k}{D_h} Nu = \frac{0.363 \text{ Btu/h.ft.°F}}{(0.75/12) \text{ ft}}(165.8) = 963 \text{ Btu/h.ft}^2\text{.°F}$$

The logarithmic mean temperature difference and then the rate of heat transfer per ft length of the tube are

$$\Delta T_{\ln} = \frac{T_e - T_i}{\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)} = \frac{140-54}{\ln\left(\frac{250-140}{250-54}\right)} = 148.9°\text{F}$$

$$\dot{Q} = hA_s\Delta T_{\ln} = (963 \text{ Btu/h.ft}^2\text{.°F})[\pi(0.75/12 \text{ ft})(1 \text{ ft})](148.9°\text{F}) = 28{,}150 \text{ Btu/h}$$

The rate of heat transfer needed to raise the temperature of water from 54 °F to 140 °F is

$$\dot{Q} = \dot{m}C_p(T_e - T_i) = (0.7\times3600 \text{ lbm/h})(0.999 \text{ Btu/lbm.°F})(140\text{ - }54)°\text{F} = 216{,}500 \text{ Btu/h}$$

Then the length of the copper tube that needs to be used becomes

$$Length = \frac{216{,}500 \text{ Btu/h}}{28{,}150 \text{ Btu/h}} = \mathbf{7.69\ ft}$$

(*b*) The friction factor, the pressure drop, and then the pumping power required to overcome this pressure drop can be determined for the case of fully developed turbulent flow to be

$$f = 0.184\,\text{Re}^{-0.2} = 0.184(31{,}165)^{-0.2} = 0.02323$$

$$\Delta P = f\frac{L}{D}\frac{\rho \mathbf{V}_m^2}{2} = 0.02323\frac{(7.69 \text{ ft})}{(0.75/12 \text{ ft})}\frac{(62 \text{ lbm/ft}^3)(3.68 \text{ ft/s})^2}{2}\left(\frac{1 \text{ lbf}}{32.174 \text{ lbm}\cdot\text{ft/s}^2}\right) = 37.27 \text{ lbf/ft}^2$$

$$\dot{W}_{pump} = \frac{\dot{m}\Delta P}{\rho} = \frac{(0.7 \text{ lbm/s})(37.27 \text{ lbf/ft}^2)}{62 \text{ lbm/ft}^3}\left(\frac{1 \text{ hp}}{550 \text{ lbf}\cdot\text{ft/s}}\right) = \mathbf{0.00078\ hp}$$

8-60 A computer is cooled by a fan blowing air through its case. The flow rate of the air, the fraction of the temperature rise of air that is due to heat generated by the fan, and the highest allowable inlet air temperature are to be determined. √

Assumptions **1** Steady flow conditions exist. **2** Heat flux is uniformly distributed. **3** Air is an ideal gas with constant properties. **4** The pressure of air is 1 atm.

Properties We assume the bulk mean temperature for air to be 300 K. The properties of air at 1 atm and this temperature are (Table A-15)

$$\rho = 1.177\ \text{kg/m}^3 \qquad \text{Pr} = 0.712$$
$$k = 0.0261\ \text{W/m.°C} \qquad \mu_b = 1.85\times10^{-5}\ \text{kg/m.s}$$
$$\upsilon = 1.57\times10^{-5}\ \text{m}^2\text{/s} \qquad \mu_{s,@\,350\text{ K}} = 2.08\times10^{-5}\ \text{kg/m.s}$$
$$C_p = 1005\ \text{J/kg.°C}$$

Analysis (*a*) Noting that the electric energy consumed by the fan is converted to thermal energy, the mass flow rate of air is

$$\dot{Q} = \dot{m}C_p(T_e - T_i) \rightarrow \dot{m} = \frac{\dot{Q} + \dot{W}_{\text{elect, fan}}}{C_p(T_e - T_i)} = \frac{(8\times10 + 25)\ \text{W}}{(1005\ \text{J/kg.°C})(10\text{°C})} = \mathbf{0.01045\ kg/s}$$

(*b*) The fraction of temperature rise of air that is due to the heat generated by the fan and its motor is

$$\dot{Q} = \dot{m}C_p\Delta T \rightarrow \Delta T = \frac{\dot{Q}}{\dot{m}C_p} = \frac{25\ \text{W}}{(0.01045\ \text{kg/s})(1005\ \text{J/kg.°C})} = \mathbf{2.38°C}$$

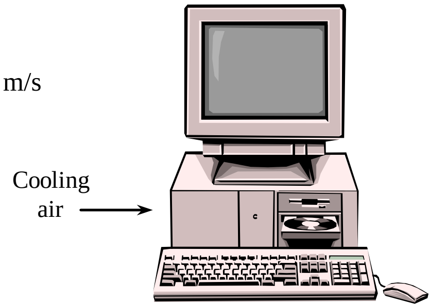
$$f = \frac{2.38\text{°C}}{10\text{°C}} = 0.238 = \mathbf{23.8\%}$$

(*c*) The mean velocity of air is

$$\dot{m} = \rho A_c V_m \rightarrow V_m = \frac{\dot{m}}{\rho A_c} = \frac{(0.01045/8)\ \text{kg/s}}{(1.177\ \text{kg/m}^3)\left[(0.003\ \text{m})(0.12\ \text{m})\right]} = 3.08\ \text{m/s}$$

and,

$$D_h = \frac{4A_c}{P} = \frac{4(0.003\ \text{m})(0.12\ \text{m})}{2(0.003\ \text{m} + 0.12\ \text{m})} = 0.00585\ \text{m}$$



Therefore,

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(3.08\ \text{m/s})(0.00585\ \text{m})}{1.57\times10^{-5}\ \text{m}^2\text{/s}} = 1148$$

which is less than 4000. Therefore, the flow is laminar. Assuming fully developed flow, the Nusselt number from is determined from Table 8-4 corresponding to a/b = 12/0.3 = 40 to be Nu = 8.24. Then,

$$h = \frac{k}{D_h}Nu = \frac{0.0261\ \text{W/m.°C}}{0.00585\ \text{m}}(8.24) = 36.8\ \text{W/m}^2\text{.°C}$$

The highest component surface temperature will occur at the exit of the duct. Assuming uniform heat flux, the air temperature at the exit is determined from

$$\dot{q} = h(T_{s,\max} - T_e) \rightarrow T_e = T_{s,\max} - \frac{\dot{q}}{h} = 70\text{°C} - \frac{[(80+25)\ \text{W}]/[8\times2(0.12\times0.18 + 0.003\times0.18)\ \text{m}^2]}{36.8\ \text{W/m}^2\text{.°C}} = 61.9\text{°C}$$

The highest allowable inlet temperature then becomes

$$T_e - T_i = 10\text{°C} \rightarrow T_i = T_e - 10\text{°C} = 61.9\text{°C} - 10\text{°C} = \mathbf{51.9°C}$$

Discussion Although the Reynolds number is less than 4000, the flow in this case will most likely be turbulent because of the electronic components that that protrude into flow. Therefore, the heat transfer coefficient determined above is probably conservative.

Review Problems

8-61 Geothermal water is supplied to a city through stainless steel pipes at a specified rate. The electric power consumption and its daily cost are to be determined, and it is to be assessed if the frictional heating during flow can make up for the temperature drop caused by heat loss.

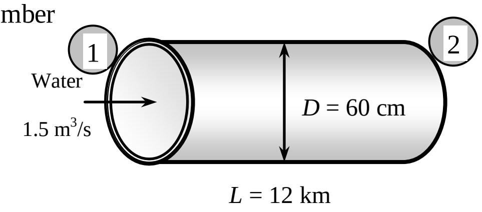
Assumptions **1** The flow is steady and incompressible. **2** The entrance effects are negligible, and thus the flow is fully developed. **3** The minor losses are negligible because of the large length-to-diameter ratio and the relatively small number of components that cause minor losses. **4** The geothermal well and the city are at about the same elevation. **5** The properties of geothermal water are the same as fresh water. **6** The fluid pressures at the wellhead and the arrival point in the city are the same.

Properties The properties of water at 110°C are $\rho = 950.6$ kg/m^3, $\mu = 0.255\times10^{-3}$ kg/m·s, and $C_p = 4.229$ kJ/kg·°C (Table A-9). The roughness of stainless steel pipes is 2×10^{-6} m (Table 8-3).

Analysis (*a*) We take point 1 at the well-head of geothermal resource and point 2 at the final point of delivery at the city, and the entire piping system as the control volume. Both points are at the same elevation ($z_2 = z_2$) and the same velocity ($\mathbf{V}_1 = \mathbf{V}_2$) since the pipe diameter is constant, and the same pressure ($P_1 = P_2$). Then the energy equation for this control volume simplifies to

$$\frac{P_1}{\rho g}+\frac{\mathbf{V}_1^2}{2g}+z_1+h_{\text{pump,u}}=\frac{P_2}{\rho g}+\frac{\mathbf{V}_2^2}{2g}+z_2+h_{\text{turbine}}+h_L \quad\rightarrow\quad h_{\text{pump,u}}=h_L$$

That is, the pumping power is to be used to overcome the head losses due to friction in flow. The mean velocity and the Reynolds number are



$$\text{V}_m=\frac{\dot{V}}{A_c}=\frac{\dot{V}}{\pi D^2/4}=\frac{1.5\text{ m}^3/\text{s}}{\pi(0.60\text{ m})^2/4}=5.305\text{ m/s}$$

$$\text{Re}=\frac{\rho\text{V}_m D}{\mu}=\frac{(950.6\text{ kg/m}^3)(5.305\text{ m/s})(0.60\text{ m})}{0.255\times10^{-3}\text{ kg/m}\cdot\text{s}}=1.186\times10^7$$

which is greater than 10,000. Therefore, the flow is turbulent. The relative roughness of the pipe is

$$\varepsilon/D=\frac{2\times10^{-6}\text{ m}}{0.60\text{ m}}=3.33\times10^{-6}$$

The friction factor can be determined from the Moody chart, but to avoid the reading error, we determine it from the Colebrook equation using an equation solver (or an iterative scheme),

$$\frac{1}{\sqrt{f}}=-2.0\log\left(\frac{\varepsilon/D}{3.7}+\frac{2.51}{\text{Re}\sqrt{f}}\right)\ \rightarrow\ \frac{1}{\sqrt{f}}=-2.0\log\left(\frac{3.33\times10^{-6}}{3.7}+\frac{2.51}{1.187\times10^7\sqrt{f}}\right)$$

It gives $f = 0.00829$. Then the pressure drop, the head loss, and the required power input become

$$\Delta P=f\,\frac{L}{D}\frac{\rho\mathbf{V}_m^2}{2}=0.00829\frac{12{,}000\text{ m}}{0.60\text{ m}}\frac{(950.6\text{ kg/m}^3)(5.305\text{ m/s})^2}{2}\left(\frac{1\text{ kN}}{1000\text{ kg}\cdot\text{m/s}}\right)\left(\frac{1\text{ kPa}}{1\text{ kN/m}^2}\right)=2218\text{ kPa}$$

$$\dot{W}_{\text{elect}}=\frac{\dot{W}_{\text{pump,u}}}{\eta_{\text{pump-motor}}}=\frac{\dot{V}\Delta P}{\eta_{\text{pump-motor}}}=\frac{(1.5\text{ m}^3/\text{s})(2218\text{ kPa})}{0.65}\left(\frac{1\text{ kW}}{1\text{ kPa}\cdot\text{m}^3/\text{s}}\right)=\mathbf{5118\text{ kW}}$$

Therefore, the pumps will consume 5118 kW of electric power to overcome friction and maintain flow.

(*b*) The daily cost of electric power consumption is determined by multiplying the amount of power used per day by the unit cost of electricity,

$$\text{Amount}=\dot{W}_{\text{elect,in}}\Delta t=(5118\text{ kW})(24\text{ h/day})=122{,}832\text{ kWh/day}$$

$$\text{Cost} = \text{Amount} \times \text{Unit cost} = (122{,}832\ \text{kWh/day})(\$0.06/\text{kWh}) = \mathbf{\$7370/day}$$

(*c*) The energy consumed by the pump (except the heat dissipated by the motor to the air) is eventually dissipated as heat due to the frictional effects. Therefore, this problem is equivalent to heating the water by a 5118 kW of resistance heater (again except the heat dissipated by the motor). To be conservative, we consider only the useful mechanical energy supplied to the water by the pump. The temperature rise of water due to this addition of energy is

$$\dot{W}_{\text{elect}} = \rho\dot{V}C_p\Delta T \;\rightarrow\; \Delta T = \frac{\eta_{\text{pump-motor}}\dot{W}_{\text{elect,in}}}{\rho\dot{V}C_p} = \frac{0.65\times(5118\ \text{kJ/s})}{(950.6\ \text{kg/m}^3)(1.5\ \text{m}^3\text{/s})(4.229\ \text{kJ/kg}\cdot{}^\circ\text{C})} = \mathbf{0.55^\circ C}$$

Therefore, the temperature of water will rise at least 0.55°C, which is more than the 0.5°C drop in temperature (in reality, the temperature rise will be more since the energy dissipation due to pump inefficiency will also appear as temperature rise of water). Thus we conclude that the frictional heating during flow can more than make up for the temperature drop caused by heat loss.

Discussion The pumping power requirement and the associated cost can be reduced by using a larger diameter pipe. But the cost savings should be compared to the increased cost of larger diameter pipe.

8-62 Geothermal water is supplied to a city through cast iron pipes at a specified rate. The electric power consumption and its daily cost are to be determined, and it is to be assessed if the frictional heating during flow can make up for the temperature drop caused by heat loss.

Assumptions **1** The flow is steady and incompressible. **2** The entrance effects are negligible, and thus the flow is fully developed. **3** The minor losses are negligible because of the large length-to-diameter ratio and the relatively small number of components that cause minor losses. **4** The geothermal well and the city are at about the same elevation. **5** The properties of geothermal water are the same as fresh water. **6** The fluid pressures at the wellhead and the arrival point in the city are the same.

Properties The properties of water at 110°C are ρ = 950.6 kg/m^3, μ = 0.255×10^{-3} kg/m·s, and C_p = 4.229 kJ/kg·°C (Table A-9). The roughness of cast iron pipes is 0.00026 m (Table 8-3).

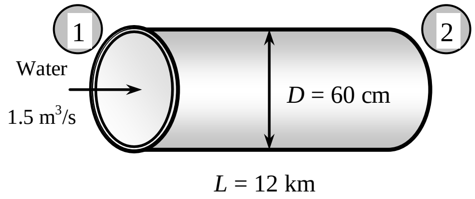
Analysis (*a*) We take point 1 at the well-head of geothermal resource and point 2 at the final point of delivery at the city, and the entire piping system as the control volume. Both points are at the same elevation ($z_2 = z_2$) and the same velocity ($\mathbf{V}_1 = \mathbf{V}_2$) since the pipe diameter is constant, and the same pressure ($P_1 = P_2$). Then the energy equation for this control volume simplifies to

$$\frac{P_1}{\rho g}+\frac{\mathbf{V}_1^2}{2g}+z_1+h_{\text{pump,u}}=\frac{P_2}{\rho g}+\frac{\mathbf{V}_2^2}{2g}+z_2+h_{\text{turbine}}+h_L \quad \rightarrow \quad h_{\text{pump,u}}=h_L$$

That is, the pumping power is to be used to overcome the head losses due to friction in flow. The mean velocity and the Reynolds number are

$$\mathbf{V}_m=\frac{\dot V}{A_c}=\frac{\dot V}{\pi D^2/4}=\frac{1.5\ \text{m}^3/\text{s}}{\pi(0.60\ \text{m})^2/4}=5.305\ \text{m/s}$$

$$\text{Re}=\frac{\rho \mathbf{V}_m D}{\mu}=\frac{(950.6\ \text{kg/m}^3)(5.305\ \text{m/s})(0.60\ \text{m})}{0.255\times10^{-3}\ \text{kg/m}\cdot\text{s}}=1.187\times10^7$$



which is greater than 10,000. Therefore, the flow is turbulent. The relative roughness of the pipe is

$$\varepsilon/D=\frac{0.00026\ \text{m}}{0.60\ \text{m}}=4.33\times10^{-4}$$

The friction factor can be determined from the Moody chart, but to avoid the reading error, we determine it from the Colebrook equation using an equation solver (or an iterative scheme),

$$\frac{1}{\sqrt f}=-2.0\log\left(\frac{\varepsilon/D}{3.7}+\frac{2.51}{\text{Re}\sqrt f}\right) \rightarrow \frac{1}{\sqrt f}=-2.0\log\left(\frac{4.33\times10^{-4}}{3.7}+\frac{2.51}{1.187\times10^7\sqrt f}\right)$$

It gives f = 0.01623 Then the pressure drop, the head loss, and the required power input become

$$\Delta P=f\frac{L}{D}\frac{\rho \text{V}_m^2}{2}=0.01623\frac{12{,}000\ \text{m}}{0.60\ \text{m}}\frac{(950.6\ \text{kg/m}^3)(5.305\ \text{m/s})^2}{2}\left(\frac{1\ \text{kN}}{1000\ \text{kg}\cdot\text{m/s}}\right)\left(\frac{1\ \text{kPa}}{1\ \text{kN/m}^2}\right)=4341\ \text{kPa}$$

$$\dot W_{\text{elect}}=\frac{\dot W_{\text{pump,u}}}{\eta_{\text{pump-motor}}}=\frac{\dot V\Delta P}{\eta_{\text{pump-motor}}}=\frac{(1.5\ \text{m}^3/\text{s})(4341\ \text{kPa})}{0.65}\left(\frac{1\ \text{kW}}{1\ \text{kPa}\cdot\text{m}^3/\text{s}}\right)=\mathbf{10{,}017\ kW}$$

Therefore, the pumps will consume 10,017 W of electric power to overcome friction and maintain flow.

(*b*) The daily cost of electric power consumption is determined by multiplying the amount of power used per day by the unit cost of electricity,

$$\text{Amount}=\dot W_{\text{elect,in}}\Delta t=(10{,}017\ \text{kW})(24\ \text{h/day})=240{,}429\ \text{kWh/day}$$

$$\text{Cost}=\text{Amount}\times\text{Unit cost}=(240{,}429\ \text{kWh/day})(\$0.06/\text{kWh})=\mathbf{\$14{,}426/day}$$

(*c*) The energy consumed by the pump (except the heat dissipated by the motor to the air) is eventually dissipated as heat due to the frictional effects. Therefore, this problem is equivalent to heating the water by a 5118 kW of resistance heater (again except the heat dissipated by the motor). To be conservative, we consider only the useful mechanical energy supplied to the water by the pump. The temperature rise of water due to this addition of energy is

$$\dot{W}_{\text{elect}} = \rho\dot{V}C_p\Delta T \;\rightarrow\; \Delta T = \frac{\eta_{\text{pump-motor}}\dot{W}_{\text{elect,in}}}{\rho\dot{V}C_p} = \frac{0.65\times(10{,}017\text{ kJ/s})}{(950.6\text{ kg/m}^3)(1.5\text{ m}^3\text{/s})(4.229\text{ kJ/kg}\cdot{}^\circ\text{C})} = \mathbf{1.08^\circ C}$$

Therefore, the temperature of water will rise at least 1.08°C, which is more than the 0.5°C drop in temperature (in reality, the temperature rise will be more since the energy dissipation due to pump inefficiency will also appear as temperature rise of water). Thus we conclude that the frictional heating during flow can more than make up for the temperature drop caused by heat loss.

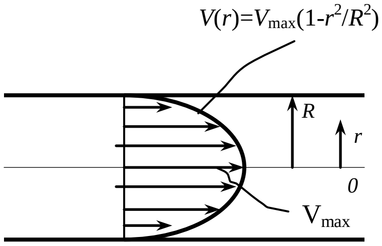
Discussion The pumping power requirement and the associated cost can be reduced by using a larger diameter pipe. But the cost savings should be compared to the increased cost of larger diameter pipe.

8-63 The velocity profile in fully developed laminar flow in a circular pipe is given. The radius of the pipe, the mean velocity, and the maximum velocity are to be determined.

Assumptions The flow is steady, laminar, and fully developed.

Analysis The velocity profile in fully developed laminar flow in a circular pipe is

$$\mathbf{V}(r) = \mathbf{V}_{\max}\left(1 - \frac{r^2}{R^2}\right)$$



The velocity profile in this case is given by

$$\mathrm{V}(r) = 6(1 - 100r^2)$$

Comparing the two relations above gives the pipe radius, the maximum velocity, and the mean velocity to be

$$R^2 = \frac{1}{100} \quad \rightarrow \quad R = \mathbf{0.10\ m}$$

$$\mathbf{V}_{\max} = \mathbf{6\ m/s}$$

$$\mathrm{V}_m = \frac{\mathrm{V}_{\max}}{2} = \frac{6\ \mathrm{m/s}}{2} = \mathbf{3\ m/s}$$

8-64E The velocity profile in fully developed laminar flow in a circular pipe is given. The volume flow rate, the pressure drop, and the useful pumping power required to overcome this pressure drop are to be determined.

Assumptions **1** The flow is steady, laminar, and fully developed. **2** The pipe is horizontal.

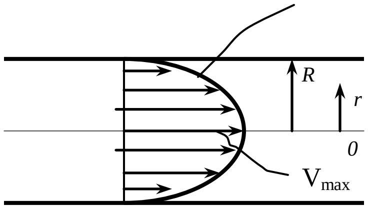
Properties The density and dynamic viscosity of water at 40°F are $\rho = 62.42$ lbm/ft^3 and $\mu = 3.74$ lbm/ft·h $= 1.039\times10^{-3}$ lbm/ft·s, respectively (Table A-9E).

Analysis The velocity profile in fully developed laminar flow in a circular pipe is

$$\mathbf{V}(r) = \mathbf{V}_{\max}\left(1 - \frac{r^2}{R^2}\right)$$

The velocity profile in this case is given by

$$\mathbf{V}(r) = 0.8(1 - 625r^2)$$



Comparing the two relations above gives the pipe radius, the maximum velocity, and the mean velocity to be

$$R^2 = \frac{1}{625} \quad \rightarrow \quad R = 0.04\text{ ft}$$

$\mathbf{V}_{\max} = 0.8$ ft/s

$$\mathbf{V}_m = \frac{\mathbf{V}_{\max}}{2} = \frac{0.8\text{ ft/s}}{2} = 0.4\text{ ft/s}$$

Then the volume flow rate and the pressure drop become

$$\dot{V} = \mathbf{V}_m A_c = \mathbf{V}_m(\pi R^2) = (0.4\text{ ft/s})[\pi(0.04\text{ ft})^2] = \mathbf{0.00201\,ft^3/s}$$

$$\dot{V}_{\text{horiz}} = \frac{\Delta P \pi D^4}{128\mu L} \quad \rightarrow \quad 0.00201\text{ ft}^3\text{/s} = \frac{(\Delta P)\pi(0.08\text{ ft})^4}{128(1.039\times10^{-3}\text{ lbm/ft}\cdot\text{s})(80\text{ ft})}\left(\frac{32.2\text{ lbm}\cdot\text{ft/s}^2}{1\text{ lbf}}\right)$$

It gives

$$\Delta P = 5.16\text{ lbf/ft}^2 = \mathbf{0.0358\,psi}$$

Then the useful pumping power requirement becomes

$$\dot{W}_{\text{pump,u}} = \dot{V}\Delta P = (0.00201\text{ ft}^3\text{/s})(5.16\text{ lbf/ft}^2)\left(\frac{1\text{ W}}{0.737\text{ lbf}\cdot\text{ft/s}}\right) = \mathbf{0.014\,W}$$

Checking The flow was assumed to be laminar. To verify this assumption, we determine the Reynolds number:

$$\text{Re} = \frac{\rho \mathbf{V}_m D}{\mu} = \frac{(62.42\text{ lbm/ft}^3)(0.4\text{ ft/s})(0.08\text{ ft})}{1.039\times10^{-3}\text{ lbm/ft}\cdot\text{s}} = 1922$$

which is less than 2300. Therefore, the flow is laminar.

Discussion Note that the pressure drop across the water pipe and the required power input to maintain flow is negligible. This is due to the very low flow velocity. Such water flows are the exception in practice rather than the rule.

8-65 A compressor is connected to the outside through a circular duct. The power used by compressor to overcome the pressure drop, the rate of heat transfer, and the temperature rise of air are to be determined.

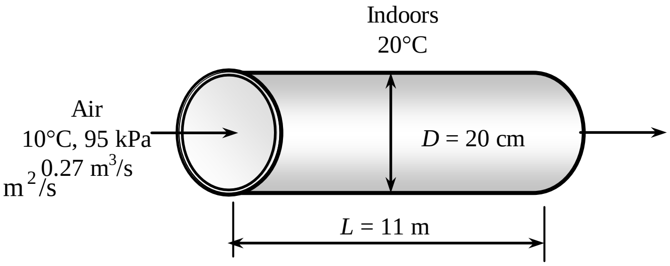
Assumptions **1** Steady flow conditions exist. **2** The inner surfaces of the duct are smooth. **3** The thermal resistance of the duct is negligible. **4** Air is an ideal gas with constant properties.

Properties We take the bulk mean temperature for air to be 15°C since the mean temperature of air at the inlet will rise somewhat as a result of heat gain through the duct whose surface is exposed to a higher temperature. The properties of air at this temperature and 1 atm pressure are (Table A-15)

$$\rho = 1.225\ \text{kg/m}^3 \qquad C_p = 1007\ \text{J/kg.°C}$$
$$k = 0.02476\ \text{W/m.°C} \qquad \text{Pr} = 0.7323$$
$$\upsilon = 1.568\times10^{-5}\ \text{m}^2/\text{s}$$

The density and kinematic viscosity at 95 kPa are

$$P = \frac{95\ \text{kPa}}{101.325\ \text{kPa}} = 0.938\ \text{atm}$$
$$\rho = (1.225\ \text{kg/m}^3)(0.938) = 1.149\ \text{kg/m}^3$$
$$\upsilon = (1.568\times10^{-5}\ \text{m}^2/\text{s})/(0.938) = 1.673\times10^{-5}\ \text{m}^2/\text{s}$$



Analysis The mean velocity of air is

$$V_m = \frac{\dot{V}}{A_c} = \frac{0.27\ \text{m}^3/\text{s}}{\pi(0.2\ \text{m})^2/4} = 8.594\ \text{m/s}$$

Then $$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(8.594\ \text{m/s})(0.2\ \text{m})}{1.673\times10^{-5}\ \text{m}^2/\text{s}} = 1.0275\times10^5$$

which is greater than 10,000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D = 10(0.2\ \text{m}) = 2\ \text{m}$$

which is shorter than the total length of the duct. Therefore, we assume fully developed flow in a smooth pipe, and determine friction factor from

$$f = (0.790\ln\text{Re} - 1.64)^{-2} = \left[0.790\ln(1.0275\times10^5) - 1.64\right]^{-0.2} = 0.01789$$

The pressure drop and the compressor power required to overcome this pressure drop are

$$\dot{m} = \rho\dot{V} = (1.149\ \text{kg/m}^3)(0.27\ \text{m}^3/\text{s}) = 0.3101\ \text{kg/s}$$

$$\Delta P = f\frac{L}{D}\frac{\rho\mathbf{V}_m^2}{2} = (0.01789)\frac{(11\ \text{m})}{(0.2\ \text{m})}\frac{(1.149\ \text{kg/m}^3)(8.594\ \text{m/s})^2}{2} = 41.74\ \text{N/m}^2$$

$$\dot{W}_{pump} = \frac{\dot{m}\Delta P}{\rho} = \frac{(0.3101\ \text{kg/s})(41.74\ \text{N/m}^2)}{1.149\ \text{kg/m}^3} = \mathbf{11.3\ W}$$

(*b*) For the fully developed turbulent flow, the Nusselt number is

$$Nu = \frac{hD}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.4} = 0.023(1.0275\times10^5)^{0.8}(0.7323)^{0.4} = 207.5$$

and $$h = \frac{k}{D_h}Nu = \frac{0.02476\ \text{W/m.°C}}{0.2\ \text{m}}(207.5) = 25.69\ \text{W/m}^2.\text{°C}$$

Disregarding the thermal resistance of the duct, the rate of heat transfer to the air in the duct becomes

$$A_s = \pi DL = \pi(0.2\ \text{m})(11\ \text{m}) = 6.912\ \text{m}^2$$

$$\dot{Q} = \frac{T_{\infty1} - T_{\infty2}}{\dfrac{1}{h_1 A_s} + \dfrac{1}{h_2 A_s}} = \frac{20 - 10}{\dfrac{1}{(25.69)(6.912)} + \dfrac{1}{(10)(6.912)}} = \mathbf{497.5\ W}$$

(*c*) The temperature rise of air in the duct is

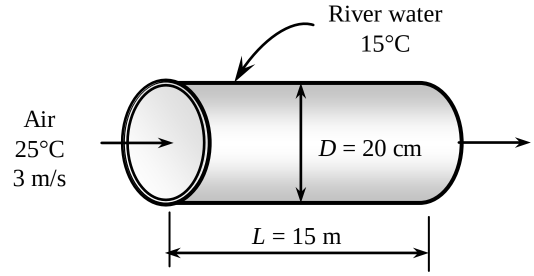
$$\dot{Q} = \dot{m}C_p\Delta T \rightarrow 497.5\ \text{W} = (0.3101\ \text{kg/s})(1007\ \text{J/kg.°C})\Delta T \rightarrow \Delta T = \mathbf{1.6°C}$$

8-66 Air enters the underwater section of a duct. The outlet temperature of the air and the fan power needed to overcome the flow resistance are to be determined.

Assumptions **1** Steady flow conditions exist. **2** The inner surfaces of the duct are smooth. **3** The thermal resistance of the duct is negligible. **4** The surface of the duct is at the temperature of the water. **5** Air is an ideal gas with constant properties. **6** The pressure of air is 1 atm.

Properties We assume the bulk mean temperature for air to be 20°C since the mean temperature of air at the inlet will drop somewhat as a result of heat loss through the duct whose surface is at a lower temperature. The properties of air at 1 atm and this temperature are (Table A-15)

$$\rho = 1.204 \text{ kg/m}^3$$
$$k = 0.02514 \text{ W/m.°C}$$
$$\upsilon = 1.516\times10^{-5} \text{ m}^2\text{/s}$$
$$C_p = 1007 \text{ J/kg.°C}$$
$$\Pr = 0.7309$$



Analysis The Reynolds number is

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(3 \text{ m/s})(0.2 \text{ m})}{1.516\times10^{-5} \text{ m}^2\text{/s}} = 3.959\times10^4$$

which is greater than 10,000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D = 10(0.2 \text{ m}) = 2 \text{ m}$$

which is much shorter than the total length of the duct. Therefore, we can assume fully developed turbulent flow in the entire duct, and determine the Nusselt number from

$$Nu = \frac{hD_h}{k} = 0.023\text{Re}^{0.8}\Pr^{0.3} = 0.023(3.959\times10^4)^{0.8}(0.7309)^{0.3} = 99.75$$

and

$$h = \frac{k}{D_h}Nu = \frac{0.02514 \text{ W/m.°C}}{0.2 \text{ m}}(99.75) = 12.54 \text{ W/m}^2\text{.°C}$$

Next we determine the exit temperature of air,

$$A_s = \pi DL = \pi(0.2 \text{ m})(15 \text{ m}) = 9.425 \text{ m}^2$$

$$\dot{m} = \rho V_m A_c = (1.204 \text{ kg/m}^3)(3 \text{ m/s})\left(\frac{\pi(0.2 \text{ m})^2}{4}\right) = 0.1135 \text{ kg/s}$$

and

$$T_e = T_s - (T_s - T_i)e^{-hA_s/(\dot{m}C_p)} = 15 - (15-25)e^{-\frac{(12.54)(9.425)}{(0.1135)(1007)}} = \mathbf{18.6°C}$$

The friction factor, pressure drop, and the fan power required to overcome this pressure drop can be determined for the case of fully developed turbulent flow in smooth pipes to be

$$f = (0.790\ln\text{Re} - 1.64)^{-2} = \left[0.790\ln(3.959\times10^4) - 1.64\right]^{-0.2} = 0.02212$$

$$\Delta P = f\frac{L}{D}\frac{\rho V_m^2}{2} = 0.02212\frac{15 \text{ m}}{0.2 \text{ m}}\frac{(1.204 \text{ kg/m}^3)(3 \text{ m/s})^2}{2}\left(\frac{1 \text{ N}}{1 \text{ kg}\cdot\text{m/s}^2}\right)\left(\frac{1 \text{ Pa}}{1 \text{ N/m}^2}\right) = 8.992 \text{ Pa}$$

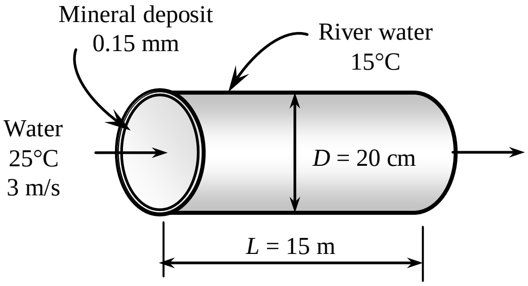
$$\dot{W}_{\text{fan}} = \frac{\dot{W}_{\text{pump,u}}}{\eta_{\text{pump-motor}}} = \frac{\dot{V}\Delta P}{\eta_{\text{pump-motor}}} = \frac{(0.1135 \text{ m}^3\text{/s})(8.992 \text{ Pa})}{0.55} = \left(\frac{1 \text{ W}}{1 \text{ Pa}\cdot\text{m}^3\text{/s}}\right) = \mathbf{1.54\ W}$$

8-67 Air enters the underwater section of a duct. The outlet temperature of the air and the fan power needed to overcome the flow resistance are to be determined.

Assumptions **1** Steady flow conditions exist. **2** The inner surfaces of the duct are smooth. **3** The thermal resistance of the duct is negligible. **4** Air is an ideal gas with constant properties. **5** The pressure of air is 1 atm.

Properties We assume the bulk mean temperature for air to be 20°C since the mean temperature of air at the inlet will drop somewhat as a result of heat loss through the duct whose surface is at a lower temperature. The properties of air at 1 atm and this temperature are (Table A-15)

$$\rho = 1.204 \text{ kg/m}^3$$
$$k = 0.02514 \text{ W/m.°C}$$
$$\upsilon = 1.516 \times 10^{-5} \text{ m}^2\text{/s}$$
$$C_p = 1007 \text{ J/kg.°C}$$
$$\Pr = 0.7309$$



Analysis The Reynolds number is

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(3 \text{ m/s})(0.2 \text{ m})}{1.516 \times 10^{-5} \text{ m}^2\text{/s}} = 3.959 \times 10^4$$

which is greater than 4000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D = 10(0.2 \text{ m}) = 2 \text{ m}$$

which is much shorter than the total length of the duct. Therefore, we can assume fully developed turbulent flow in the entire duct, and determine the Nusselt number and *h* from

$$Nu = \frac{hD_h}{k} = 0.023 \text{Re}^{0.8} \Pr^{0.3} = 0.023(3.959 \times 10^4)^{0.8}(0.7309)^{0.3} = 99.75$$

and

$$h = \frac{k}{D_h} Nu = \frac{0.02514 \text{ W/m.°C}}{0.2 \text{ m}}(99.75) = 12.54 \text{ W/m}^2\text{.°C}$$

Next we determine the exit temperature of air,

$$A_s = \pi DL = \pi(0.2 \text{ m})(15 \text{ m}) = 9.425 \text{ m}^2$$

$$\dot{m} = \rho V_m A_c = (1.204 \text{ kg/m}^3)(3 \text{ m/s})\left(\frac{\pi(0.2 \text{ m})^2}{4}\right) = 0.1135 \text{ kg/s}$$

The unit thermal resistance of the mineral deposit is

$$R_{\text{mineral}} = \frac{L}{k} = \frac{0.0015 \text{ m}}{3 \text{ W/m.°C}} = 0.0005 \text{ m}^2\text{.°C/W}$$

which is much less than (under 1%) the unit convection resistance,

$$R_{\text{conv}} = \frac{1}{h} = \frac{1}{12.54 \text{ W/m}^2\text{.°C}} = 0.0797 \text{ m}^2\text{.°C/W}$$

Therefore, the effect of 0.15 mm thick mineral deposit on heat transfer is negligible.

Next we determine the exit temperature of air,

$$T_e = T_s - (T_s - T_i)e^{-hA/(\dot{m}C_p)} = 15 - (15 - 25)e^{-\frac{(12.54)(9.425)}{(0.1135)(1007)}} = \mathbf{18.6°C}$$

The friction factor, pressure drop, and the fan power required to overcome this pressure drop can be determined for the case of fully developed turbulent flow in smooth pipes to be

$$f = (0.790 \ln \text{Re} - 1.64)^{-2} = \left[0.790 \ln(3.959 \times 10^4) - 1.64\right]^{-0.2} = 0.02212$$

$$\Delta P = f\,\frac{L}{D}\frac{\rho V_m^2}{2} = 0.02212\frac{15\text{ m}}{0.2\text{ m}}\frac{(1.204\text{ kg/m}^3)(3\text{ m/s})^2}{2}\left(\frac{1\text{ N}}{1\text{ kg}\cdot\text{m/s}^2}\right)\left(\frac{1\text{ Pa}}{1\text{ N/m}^2}\right) = 8.992\text{ Pa}$$

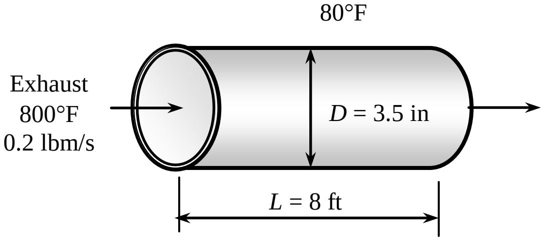
$$\dot{W}_{\text{fan}} = \frac{\dot{W}_{\text{pump,u}}}{\eta_{\text{pump-motor}}} = \frac{\dot{V}\Delta P}{\eta_{\text{pump-motor}}} = \frac{(0.1135\text{ m}^3\text{/s})(8.992\text{ Pa})}{0.55} = \left(\frac{1\text{ W}}{1\text{ Pa}\cdot\text{m}^3\text{/s}}\right) = \mathbf{1.54\ W}$$

8-68E The exhaust gases of an automotive engine enter a steel exhaust pipe. The velocity of exhaust gases at the inlet and the temperature of exhaust gases at the exit are to be determined.

Assumptions **1** Steady flow conditions exist. **2** The inner surfaces of the pipe are smooth. **3** The thermal resistance of the pipe is negligible. **4** Exhaust gases have the properties of air, which is an ideal gas with constant properties.

Properties We take the bulk mean temperature for exhaust gases to be 700°C since the mean temperature of gases at the inlet will drop somewhat as a result of heat loss through the exhaust pipe whose surface is at a lower temperature. The properties of air at this temperature and 1 atm pressure are (Table A-15)

$$\rho = 0.03422\ \text{lbm/ft}^3 \qquad C_p = 0.2535\ \text{Btu/lbm.°F}$$
$$k = 0.0280\ \text{Btu/h.ft.°F} \qquad \text{Pr} = 0.694$$
$$\upsilon = 0.5902\times10^{-3}\ \text{ft}^2\text{/s}$$



Noting that 1 atm = 14.7 psia, the pressure in atm is P = (15.5 psia)/(14.7 psia) = 1.054 atm. Then,

$$\rho = (0.03422\ \text{lbm/ft}^3)(1.054) = 0.03608\ \text{lbm/ft}^3$$
$$\upsilon = (0.5902\times10^{-3}\ \text{ft}^2\text{/s})/(1.054) = 0.5598\times10^{-3}\ \text{ft}^2\text{/s}$$

Analysis (a) The velocity of exhaust gases at the inlet of the exhaust pipe is

$$\dot{m} = \rho V_m A_c \longrightarrow V_m = \frac{\dot{m}}{\rho A_c} = \frac{0.2\ \text{lbm/s}}{(0.03608\ \text{lbm/ft}^3)\left(\pi(3.5/12\ \text{ft})^2/4\right)} = \mathbf{82.97\ ft/s}$$

(b) The Reynolds number is

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(82.97\ \text{ft/s})(3.5/12\ \text{ft})}{0.5598\times10^{-3}\ \text{ft}^2\text{/s}} = 43{,}231$$

which is greater than 10,000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D = 10(3.5/12\ \text{ft}) = 2.917\ \text{ft}$$

which are shorter than the total length of the duct. Therefore, we can assume fully developed turbulent flow in the entire duct, and determine the Nusselt number from

$$Nu = \frac{hD_h}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.3} = 0.023(43{,}231)^{0.8}(0.694)^{0.3} = 105.4$$

and $$h_i = h = \frac{k}{D_h}Nu = \frac{0.03422\ \text{Btu/h.ft.°F}}{(3.5/12)\ \text{ft}}(105.4) = 10.12\ \text{Btu/h.ft}^2\text{.°F}$$

$$A_s = \pi DL = \pi(3.5/12\ \text{ft})(8\ \text{ft}) = 7.33\ \text{ft}^2$$

In steady operation, heat transfer from exhaust gases to the duct must be equal to the heat transfer from the duct to the surroundings, which must be equal to the energy loss of the exhaust gases in the pipe. That is,

$$\dot{Q} = \dot{Q}_{\text{internal}} = \dot{Q}_{\text{external}} = \Delta\dot{E}_{\text{exhaust gases}}$$

Assuming the duct to be at an average temperature of T_s, the quantities above can be expressed as

$\dot{Q}_{\text{internal}}$: $$\dot{Q} = h_i A_s \Delta T_{\ln} = h_i A_s \frac{T_e - T_i}{\ln\left(\dfrac{T_s - T_e}{T_s - T_i}\right)} \rightarrow \dot{Q} = (10.12\ \text{Btu/h.ft}^2\text{.°F})(7.33\ \text{ft}^2)\frac{T_e - 800\text{°F}}{\ln\left(\dfrac{T_s - T_e}{T_s - 800}\right)}$$

$\dot{Q}_{\text{external}}$: $$\dot{Q} = h_o A_s (T_s - T_o) \rightarrow \dot{Q} = (3\ \text{Btu/h.ft}^2\text{.°F})(7.33\ \text{ft}^2)(T_s - 80)\text{°F}$$

$\Delta\dot{E}_{\text{exhaust gases}}$: $$\dot{Q} = \dot{m}C_p(T_e - T_i) \rightarrow \dot{Q} = (0.2\times3600\ \text{lbm/h})(0.2535\ \text{Btu/lbm.°F})(800 - T_e)\text{°F}$$

This is a system of three equations with three unknowns whose solution is

$$\dot{Q} = \mathbf{11{,}635\ Btu/h},\ T_e = \mathbf{736.3°F},\ \text{and}\ T_s = 609.1\text{°F}$$

Therefore, the exhaust gases will leave the pipe at 865°F.

8-69 Hot water enters a cast iron pipe whose outer surface is exposed to cold air with a specified heat transfer coefficient. The rate of heat loss from the water and the exit temperature of the water are to be determined.

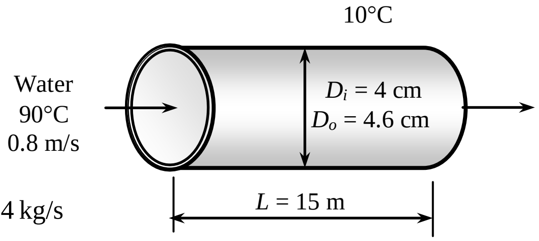
Assumptions **1** Steady flow conditions exist. **2** The inner surfaces of the pipe are smooth.

Properties We assume the water temperature not to drop significantly since the pipe is not very long. We will check this assumption later. The properties of water at 90°C are (Table A-9)

$$\rho = 965.3\ \text{kg/m}^3; \qquad k = 0.675\ \text{W/m.°C}$$

$$\upsilon = \mu/\rho = 0.326\times10^{-6}\ \text{m}^2\text{/s}; \quad C_p = 4206\ \text{J/kg.°C}$$

$$\text{Pr} = 1.96$$



Analysis (a) The mass flow rate of water is

$$\dot{m} = \rho A_c V = (965.3\ \text{kg/m}^3)\frac{\pi(0.04\ \text{m})^2}{4}(0.8\ \text{m/s}) = 0.9704\ \text{kg/s}$$

The Reynolds number is

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(0.8\ \text{m/s})(0.04\ \text{m})}{0.326\times10^{-6}\ \text{m}^2\text{/s}} = 98{,}062$$

which is greater than 10,000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D = 10(0.04\ \text{m}) = 0.4\ \text{m}$$

which are much shorter than the total length of the pipe. Therefore, we can assume fully developed turbulent flow in the entire pipe. The friction factor corresponding to Re = 98,062 and ε/D = (0.026 cm)/(4 cm) = 0.0065 is determined from the Moody chart to be f = 0.034. Then the Nusselt number becomes

$$Nu = \frac{hD_h}{k} = 0.125 f\ \text{Re}\,\text{Pr}^{1/3} = 0.125\times0.034\times98{,}062\times1.96^{1/3} = 521.6$$

and $$h_i = h = \frac{k}{D_h}Nu = \frac{0.675\ \text{W/m.°C}}{0.04\ \text{m}}(521.6) = 8801\ \text{W/m}^2\text{.°C}$$

which is much greater than the convection heat transfer coefficient of 15 W/m^2.°C. Therefore, the convection thermal resistance inside the pipe is negligible, and thus the inner surface temperature of the pipe can be taken to be equal to the water temperature. Also, we expect the pipe to be nearly isothermal since it is made of thin metal (we check this later). Then the rate of heat loss from the pipe will be the sum of the convection and radiation from the outer surface at a temperature of 90°C, and is determined to be

$$A_o = \pi D_0 L = \pi(0.046\ \text{m})(15\ \text{m}) = 2.168\ \text{m}^2$$

$$\dot{Q}_{conv} = h_o A_o(T_s - T_{surr}) = (15\ \text{W/m}^2\text{.°C})(2.168\ \text{m}^2)(90-10)\text{°C} = 2601\ \text{W}$$

$$\dot{Q}_{rad} = \varepsilon A_0 \sigma(T_s{}^4 - T_{surr}{}^4) = (0.7)(2.168\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\text{.K}^4)\left[(90+273\ \text{K})^4 - (10+273\ \text{K})^4\right] = 942\ \text{W}$$

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad} = 2601 + 942 = \mathbf{3543\ W}$$

(b) The temperature at which water leaves the basement is

$$\dot{Q} = \dot{m}C_p(T_i - T_e) \longrightarrow T_e = T_i - \frac{\dot{Q}}{\dot{m}C_p} = 90\text{°C} - \frac{3543\ \text{W}}{(0.9704\ \text{kg/s})(4206\ \text{J/kg.°C})} = \mathbf{89.1°C}$$

The result justifies our assumption that the temperature drop of water is negligible. Also, the thermal resistance of the pipe and temperature drop across it are

$$R_{pipe} = \frac{\ln(D_2/D_1)}{4\pi kL} = \frac{\ln(4.6/4)}{4\pi(52\ \text{W/m.°C})(15\ \text{m})} = 1.65\times10^{-5}\ \text{°C/W}$$

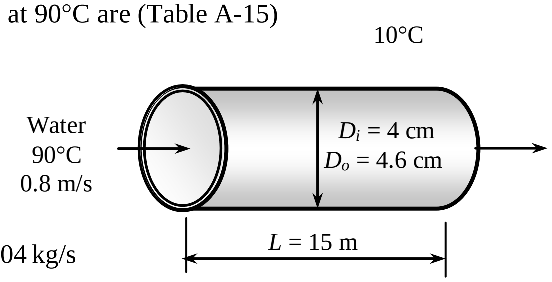
$$\Delta T_{pipe} = \dot{Q}_{total} R_{pipe} = (3543\ \text{W})(1.65\times10^{-5}\ \text{°C/W}) = 0.06\text{°C}$$

which justifies our assumption that the temperature drop across the pipe is negligible.

8-70 Hot water enters a copper pipe whose outer surface is exposed to cold air with a specified heat transfer coefficient. The rate of heat loss from the water and the exit temperature of the water are to be determined.

Assumptions **1** Steady flow conditions exist. **2** The inner surfaces of the pipe are smooth.

Properties We assume the water temperature not to drop significantly since the pipe is not very long. We will check this assumption later. The properties of water at 90°C are (Table A-15)



$$\rho = 965.3\ \text{kg/m}^3; \qquad k = 0.675\ \text{W/m.°C}$$

$$\upsilon = \mu/\rho = 0.326\times10^{-6}\ \text{m}^2\text{/s}; \quad C_p = 4206\ \text{J/kg.°C}$$

$$\text{Pr} = 1.96$$

Analysis (a) The mass flow rate of water is

$$\dot{m} = \rho A_c V = (965.3\ \text{kg/m}^3)\frac{\pi(0.04\ \text{m})^2}{4}(0.8\ \text{m/s}) = 0.9704\ \text{kg/s}$$

The Reynolds number is

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(0.8\ \text{m/s})(0.04\ \text{m})}{0.326\times10^{-6}\ \text{m}^2\text{/s}} = 98{,}062$$

which is greater than 4000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D = 10(0.04\ \text{m}) = 0.4\ \text{m}$$

which are much shorter than the total length of the pipe. Therefore, we can assume fully developed turbulent flow in the entire pipe. Assuming the copper pipe to be smooth, the Nusselt number is determined to be

$$Nu = \frac{hD_h}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.3} = 0.023\times98{,}062^{0.8}\times1.96^{0.3} = 277.1$$

and $$h_i = h = \frac{k}{D_h}Nu = \frac{0.675\ \text{W/m.°C}}{0.04\ \text{m}}(277.1) = 4676\ \text{W/m}^2\text{.°C}$$

which is much greater than the convection heat transfer coefficient of 15 W/m^2.°C. Therefore, the convection thermal resistance inside the pipe is negligible, and thus the inner surface temperature of the pipe can be taken to be equal to the water temperature. Also, we expect the pipe to be nearly isothermal since it is made of thin metal (we check this later). Then the rate of heat loss from the pipe will be the sum of the convection and radiation from the outer surface at a temperature of 90°C, and is determined to be

$$A_o = \pi D_0 L = \pi(0.046\ \text{m})(15\ \text{m}) = 2.168\ \text{m}^2$$

$$\dot{Q}_{conv} = h_o A_o(T_s - T_{surr}) = (15\ \text{W/m}^2\text{.°C})(2.168\ \text{m}^2)(90-10)\text{°C} = 2601\ \text{W}$$

$$\dot{Q}_{rad} = \varepsilon A_0\sigma(T_s{}^4 - T_{surr}{}^4)$$
$$= (0.7)(2.168\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\text{.K}^4)[(90+273\ \text{K})^4 - (10+273\ \text{K})^4] = 942\ \text{W}$$

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad} = 2601 + 942 = \mathbf{3543\ W}$$

(b) The temperature at which water leaves the basement is

$$\dot{Q} = \dot{m}C_p(T_i - T_e) \longrightarrow T_e = T_i - \frac{\dot{Q}}{\dot{m}C_p} = 90\text{°C} - \frac{3544\ \text{W}}{(0.970\ \text{kg/s})(4206\ \text{J/kg.°C})} = \mathbf{89.1°C}$$

The result justifies our assumption that the temperature drop of water is negligible. Also, the thermal resistance of the pipe and temperature drop across it are

$$R_{pipe} = \frac{\ln(D_2/D_1)}{4\pi kL} = \frac{\ln(4.6/4)}{4\pi(386\ \text{W/m.°C})(15\ \text{m})} = 1.92\times10^{-6}\ \text{°C/W}$$

$$\Delta T_{pipe} = \dot{Q}_{total}R_{pipe} = (3543\ \text{W})(1.92\times10^{-6}\ \text{°C/W}) = 0.007\text{°C}$$

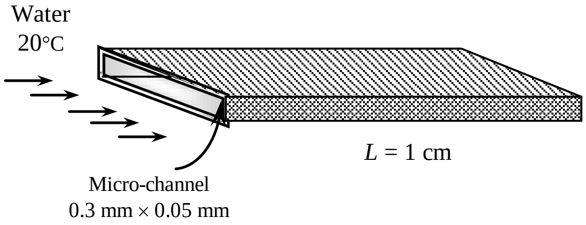
which justifies our assumption that the temperature drop across the pipe is negligible.

8-71 Integrated circuits are cooled by water flowing through a series of microscopic channels. The temperature rise of water across the microchannels and the average surface temperature of the microchannels are to be determined.

Assumptions **1** Steady flow conditions exist. **2** The inner surfaces of the microchannels are smooth. **3** Entrance effects are disregarded. **4** Any heat transfer from the side and cover surfaces are neglected.

Properties We assume the bulk mean temperature of water to be the inlet temperature of 20°C since the mean temperature of water at the inlet will rise somewhat as a result of heat gain through the microscopic channels. The properties of water at 20°C and the viscosity at the anticipated surface temperature of 25°C are (Table A-9)

$$\rho = 998\ \text{kg/m}^3$$
$$k = 0.598\ \text{W/m.°C}$$
$$\upsilon = \mu/\rho = 1.004\times10^{-6}\ \text{m}^2\text{/s}$$
$$C_p = 4182\ \text{J/kg.°C};\ \ \text{Pr} = 7.01$$



Analysis (*a*) The mass flow rate of water is

$$\dot{m} = \rho\dot{V} = (998\ \text{kg/m}^3)(0.01\times10^{-3}\ \text{m}^3\text{/s}) = 0.00998\ \text{kg/s}$$

The temperature rise of water as it flows through the micro channels is

$$\dot{Q} = \dot{m}C_p\Delta T \longrightarrow \Delta T = \frac{\dot{Q}}{\dot{m}C_p} = \frac{50\ \text{J/s}}{(0.00998\ \text{kg/s})(4182\ \text{J/kg°C})} = \mathbf{1.2°C}$$

(b) The Reynolds number is

$$V_m = \frac{\dot{V}}{A_c} = \frac{0.01\times10^{-3}\ \text{m}^3\text{/s}}{(0.05\times10^{-3}\ \text{m})(0.3\times10^{-3}\ \text{m})\times100} = 6.667\ \text{m/s}$$

$$D_h = \frac{4A_c}{P} = \frac{4(0.05\times10^{-3}\ \text{m})(0.3\times10^{-3}\ \text{m})}{2(0.05\times10^{-3}\ \text{m} + 0.3\times10^{-3}\ \text{m})} = 8.571\times10^{-5}\ \text{m}$$

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(6.667\ \text{m/s})(8.57\times10^{-5}\ \text{m})}{1.004\times10^{-6}\ \text{m}^2\text{/s}} = 569.1$$

which is less than 2300. Therefore, the flow is laminar, and the thermal entry length in this case is

$$L_t = 0.05\,\text{Re}\,\text{Pr}\,D_h = 0.05(569.1)(7.01)(8.571\times10^{-5}\ \text{m}) = 0.0171\ \text{m}$$

which is longer than the total length of the channels. Therefore, we can assume thermally developing flow, and determine the Nusselt number from (actually, the relation below is for circular tubes)

$$Nu = \frac{hD}{k} = 3.66 + \frac{0.065(D/L)\,\text{Re}\,\text{Pr}}{1+0.04\left[(D/L)\,\text{Re}\,\text{Pr}\right]^{2/3}} = 3.66 + \frac{0.065\left(\dfrac{8.571\times10^{-5}\ \text{m}}{0.01\ \text{m}}\right)(569.1)(7.01)}{1+0.04\left[\left(\dfrac{8.571\times10^{-5}\ \text{m}}{0.01\ \text{m}}\right)(569.1)(7.01)\right]^{2/3}} = 5.224$$

and $$h = \frac{k}{D_h}Nu = \frac{0.598\ \text{W/m.°C}}{8.571\times10^{-5}\ \text{m}}(5.224) = 36{,}445\ \text{W/m}^2\text{.°C}$$

Then the average surface temperature of the base of the micro channels is determined to be

$$A_s = pL = 2(0.3+0.05)\times10^{-3}\times0.01 = 7\times10^{-6}\ \text{m}^2$$

$$\dot{Q} = hA_s(T_{s,ave} - T_{m,ave})$$

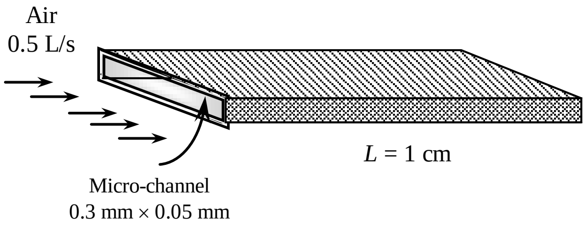
$$T_{s,ave} = T_{m,ave} + \frac{\dot{Q}}{hA_s} = \left(\frac{20+21.2}{2}\right)\text{°C} + \frac{(50/100)\ \text{W}}{(36{,}445\ \text{W/m}^2\text{.°C})(7\times10^{-6}\ \text{m}^2)} = \mathbf{22.6\ °C}$$

8-72 Integrated circuits are cooled by air flowing through a series of microscopic channels. The temperature rise of air across the microchannels and the average surface temperature of the microchannels are to be determined.

Assumptions **1** Steady flow conditions exist. **2** The inner surfaces of the microchannels are smooth. **3** Entrance effects are disregarded. **4** Any heat transfer from the side and cover surfaces are neglected. **5** Air is an ideal gas with constant properties. **6** The pressure of air is 1 atm.

Properties We assume the bulk mean temperature for air to be 60°C since the mean temperature of air at the inlet will rise somewhat as a result of heat gain through the microscopic channels whose base areas are exposed to uniform heat flux. The properties of air at 1 atm and 60°C are (Table A-15)

$$\begin{aligned} \rho &= 1.060 \text{ kg/m}^3 \\ k &= 0.02808 \text{ W/m.°C} \\ \upsilon &= 1.895\times10^{-5} \text{ m}^2\text{/s} \\ C_p &= 1007 \text{ J/kg.°C} \\ \Pr &= 0.7202 \end{aligned}$$



Analysis (a) The mass flow rate of air is

$$\dot{m} = \rho\dot{V} = (1.060 \text{ kg/m}^3)(0.5\times10^{-3} \text{ m}^3\text{/s}) = 5.298\times10^{-4} \text{ kg/s}$$

The temperature rise of air as it flows through the micro channels is

$$\dot{Q} = \dot{m}C_p\Delta T \;\rightarrow\; \Delta T = \frac{\dot{Q}}{\dot{m}C_p} = \frac{50 \text{ J/s}}{(5.298\times10^{-4} \text{ kg/s})(1007 \text{ J/kg.°C})} = \mathbf{93.7°C}$$

(b) The Reynolds number is

$$V_m = \frac{\dot{V}}{A_c} = \frac{(0.5\times10^{-3}/100) \text{ m}^3\text{/s}}{(0.05\times10^{-3} \text{ m})(0.3\times10^{-3} \text{ m})} = 333.3 \text{ m/s}$$

$$D_h = \frac{4A_c}{P} = \frac{4(0.05\times10^{-3} \text{ m})(0.3\times10^{-3} \text{ m})}{2(0.05\times10^{-3} \text{ m} + 0.3\times10^{-3} \text{ m})} = 8.571\times10^{-5} \text{ m}$$

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(333.3 \text{ m/s})(8.57\times10^{-5} \text{ m})}{1.895\times10^{-5} \text{ m}^2\text{/s}} = 1508$$

which is smaller than 2300. Therefore, the flow is laminar and the thermal entry length in this case is

$$L_t = 0.05 \,\text{Re}\,\Pr D_h = 0.05(1508)(0.7202)(8.571\times10^{-5} \text{ m}) = 0.004653 \text{ m}$$

which is 42% of the total length of the channels. Therefore, we can assume thermally developing flow, and determine the Nusselt number from (actually, the relation below is for circular tubes)

$$Nu = \frac{hD}{k} = 3.66 + \frac{0.065(D/L)\,\text{Re}\Pr}{1+0.04\left[(D/L)\,\text{Re}\Pr\right]^{2/3}} = 3.66 + \frac{0.065\left(\dfrac{8.571\times10^{-5} \text{ m}}{0.01 \text{ m}}\right)(1508)(0.7202)}{1+0.04\left[\left(\dfrac{8.571\times10^{-5} \text{ m}}{0.01 \text{ m}}\right)(1508)(0.7202)\right]^{2/3}} = 4.174$$

and $$h = \frac{k}{D_h}Nu = \frac{0.02808 \text{ W/m.°C}}{8.571\times10^{-5} \text{ m}}(4.174) = 1368 \text{ W/m}^2\text{.°C}$$

Then the average surface temperature of the base of the micro channels becomes

$$A_s = pL = 2(0.3+0.05)\times10^{-3}\times0.01 = 7\times10^{-6} \text{ m}^2$$

$$\dot{Q} = hA_s(T_{s,ave} - T_{m,ave})$$

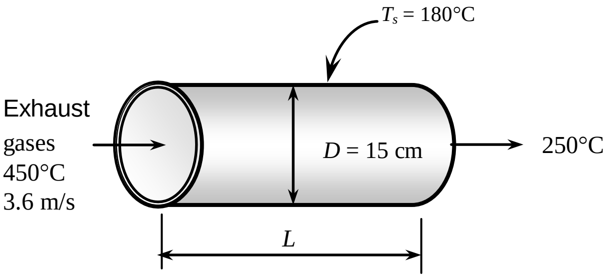
$$T_{s,ave} = T_{m,ave} + \frac{\dot{Q}}{hA_s} = \left(\frac{20+113.7}{2}\right)\text{°C} + \frac{(50/100) \text{ W}}{(1368 \text{ W/m}^2\text{.°C})(7\times10^{-6} \text{ m}^2)} = \mathbf{119.1°C}$$

8-73 Hot exhaust gases flow through a pipe. For a specified exit temperature, the pipe length is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The inner surface of the pipe is smooth. **3** Air is an ideal gas with constant properties. **4** The pressure of air is 1 atm.

Properties The properties of air at 1 atm and the bulk mean temperature of (450+250)/2 = 350°C are (Table A-15)

$$\rho = 0.5664 \text{ kg/m}^3$$
$$k = 0.04721 \text{ W/m.°C}$$
$$\upsilon = 5.475\times10^{-5} \text{ m}^2\text{/s}$$
$$C_p = 1056 \text{ J/kg.°C}$$
$$\text{Pr} = 0.6937$$



Analysis The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_m D}{\upsilon} = \frac{(3.6 \text{ m/s})(0.15 \text{ m})}{5.475\times10^{-5} \text{ m}^2\text{/s}} = 9864$$

which is greater than 10,000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D = 10(0.15 \text{ m}) = 1.5 \text{ m}$$

which is probably much shorter than the total length of the duct. Therefore, we can assume fully developed turbulent flow in the entire duct, and determine the Nusselt number from

$$Nu = \frac{hD}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.3} = 0.023(9864)^{0.8}(0.6937)^{0.3} = 32.31$$

Heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.04721 \text{ W/m.°C}}{0.15 \text{ m}}(32.31) = 10.17 \text{ W/m}^2\text{.°C}$$

The logarithmic mean temperature difference is

$$\Delta T_{\ln} = \frac{T_e - T_i}{\ln\left(\dfrac{T_s - T_e}{T_s - T_i}\right)} = \frac{250-450}{\ln\left(\dfrac{180-250}{180-450}\right)} = 148.2\text{°C}$$

The rate of heat loss from the exhaust gases can be expressed as

$$\dot{Q} = hA_s\Delta T_{\ln} = (10.17 \text{ W/m}^2\text{.°C})[\pi(0.15 \text{ m})L](148.2\text{°C}) = 710.25L$$

where L is the length of the pipe. The rate of heat loss can also be determined from

$$\dot{m} = \rho V A_c = (0.5664 \text{ kg/m}^3)(3.6 \text{ m/s})\left[\pi(0.15 \text{ m})^2/4\right] = 0.03603 \text{ kg/s}$$

$$\dot{Q} = \dot{m}C_p\Delta T = (0.03603 \text{ kg/s})(1056 \text{ J/kg.°C})(450-250)\text{°C} = 7612 \text{ W}$$

Setting this equal to rate of heat transfer expression above, the pipe length is determined to be

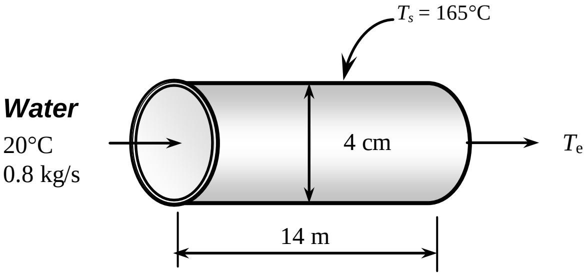
$$\dot{Q} = 710.25L = 7612 \text{ W} \longrightarrow L = \mathbf{10.72\ m}$$

8-74 Water is heated in a heat exchanger by the condensing geothermal steam. The exit temperature of water and the rate of condensation of geothermal steam are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The inner surfaces of the tube are smooth. **3** Air is an ideal gas with constant properties. **4** The surface temperature of the pipe is 165°C, which is the temperature at which the geothermal steam is condensing.

Properties The properties of water at the anticipated mean temperature of 85°C are (Table A-9)

$$\rho = 968.1\ \text{kg/m}^3$$
$$k = 0.673\ \text{W/m.°C}$$
$$C_p = 4201\ \text{J/kg.°C}$$
$$\text{Pr} = 2.08$$
$$\upsilon = \frac{\mu}{\rho} = \frac{0.333\times10^{-3}\ \text{kg/m.s}}{968.1\ \text{kg/m}^3} = 3.44\times10^{-7}\ \text{m}^2\text{/s}$$
$$h_{fg\,@165°\text{C}} = 2066.5\ \text{kJ/kg}$$



Analysis The velocity of water and the Reynolds number are

$$\dot m = \rho A\mathbf{V}_m \longrightarrow 0.8\ \text{kg/s} = (968.1\ \text{kg/m}^3)\pi\frac{(0.04\ \text{m})^2}{4}\mathbf{V}_m \longrightarrow \mathbf{V}_m = 0.5676\ \text{m/s}$$

$$\text{Re} = \frac{\mathbf{V}_m D}{\upsilon} = \frac{(0.5676\ \text{m/s})(0.04\ \text{m})}{3.44\times10^{-7}\ \text{m}^2\text{/s}} = 76{,}471$$

which is greater than 10,000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D = 10(0.04\ \text{m}) = 0.4\ \text{m}$$

which is much shorter than the total length of the duct. Therefore, we can assume fully developed turbulent flow in the entire duct, and determine the Nusselt number from

$$Nu = \frac{hD}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.4} = 0.023(76{,}471)^{0.8}(2.08)^{0.4} = 248.7$$

Heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.673\ \text{W/m.°C}}{0.04\ \text{m}}(248.7) = 4185\ \text{W/m}^2\text{.°C}$$

Next we determine the exit temperature of air,

$$A_s = \pi DL = \pi(0.04\ \text{m})(14\ \text{m}) = 1.759\ \text{m}^2$$

$$T_e = T_s - (T_s - T_i)e^{-hA_s/(\dot m C_p)} = 165 - (165-20)e^{-\frac{(4185)(1.759)}{(0.5676)(4201)}} = \mathbf{148.8°C}$$

The logarithmic mean temperature difference is

$$\Delta T_{\ln} = \frac{T_e - T_i}{\ln\left(\dfrac{T_s - T_e}{T_s - T_i}\right)} = \frac{148.8 - 20}{\ln\left(\dfrac{165-148.8}{165-20}\right)} = 58.8°\text{C}$$

The rate of heat loss from the exhaust gases can be expressed as

$$\dot Q = hA_s\Delta T_{\ln} = (4185\ \text{W/m}^2\text{.°C})(1.759\ \text{m}^2)(58.8°\text{C}) = 432{,}820\ \text{W}$$

The rate of condensation of steam is determined from

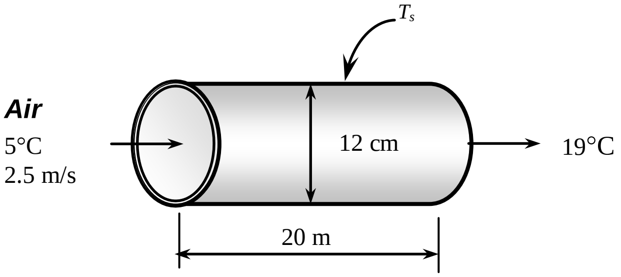
$$\dot Q = \dot m h_{fg} \longrightarrow 432.820\ \text{kW} = \dot m(2066.5\ \text{kJ/kg}) \longrightarrow \dot m = \mathbf{0.204\ kg/s}$$

8-75 Cold-air flows through an isothermal pipe. The pipe temperature is to be estimated.

Assumptions **1** Steady operating conditions exist. **2** The inner surface of the duct is smooth. **3** Air is an ideal gas with constant properties. **4** The pressure of air is 1 atm.

Properties The properties of air at 1 atm and the bulk mean temperature of (5+19) / 2 = 12°C are (Table A-15)

$$\rho = 1.238\ \text{kg/m}^3$$
$$k = 0.02454\ \text{W/m.°C}$$
$$\upsilon = 1.444\times10^{-5}\ \text{m}^2\text{/s}$$
$$C_p = 1007\ \text{J/kg.°C}$$
$$\text{Pr} = 0.7331$$



Analysis The rate of heat transfer to the air is

$$\dot{m} = \rho A_c \mathbf{V}_m = (1.238\ \text{kg/m}^3)\pi\frac{(0.12\ \text{m})^2}{4}(2.5\ \text{m/s}) = 0.03499\ \text{m/s}$$

$$\dot{Q} = \dot{m}C_p\Delta T = (0.03499\ \text{kg/s})(1007\ \text{J/kg.°C})(19-5)\text{°C} = 493.1\ \text{W}$$

Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{(2.5\ \text{m/s})(0.12\ \text{m})}{1.444\times10^{-5}\ \text{m}^2\text{/s}} = 20{,}775$$

which is greater than 10,000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D = 10(0.12\ \text{m}) = 1.2\ \text{m}$$

which is much shorter than the total length of the duct. Therefore, we can assume fully developed turbulent flow in the entire duct, and determine the Nusselt number from

$$Nu = \frac{hD}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.4} = 0.023(20{,}775)^{0.8}(0.7331)^{0.4} = 57.79$$

Heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.02454\ \text{W/m.°C}}{0.12\ \text{m}}(57.79) = 11.82\ \text{W/m}^2\text{.°C}$$

The logarithmic mean temperature difference is determined from

$$\dot{Q} = hA_s\Delta T_{\ln} \longrightarrow 493.1\ \text{W} = (11.82\ \text{W/m}^2\text{.°C})[\pi(0.12\ \text{m})(20\ \text{m})]\Delta T_{\ln} \longrightarrow \Delta T_{\ln} = 5.535\text{°C}$$

Then the pipe temperature is determined from the definition of the logarithmic mean temperature difference

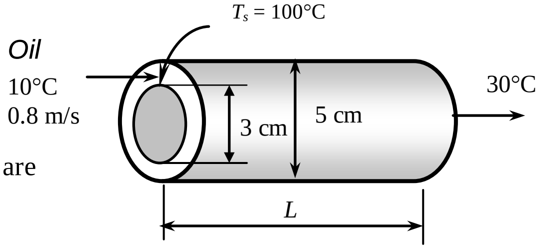
$$\Delta T_{\ln} = \frac{T_e - T_i}{\ln\left(\dfrac{T_s - T_e}{T_s - T_i}\right)} \longrightarrow 5.535\text{°C} = \frac{19-5}{\ln\left(\dfrac{T_s - 19}{T_s - 5}\right)} \longrightarrow T_s = \mathbf{3.8°C}$$

8-76 Oil is heated by saturated steam in a double-pipe heat exchanger. The tube length is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The surfaces of the tube are smooth. **3** Air is an ideal gas with constant properties.

Properties The properties of oil at the average temperature of (10+30)/2=20°C are (Table A-13)

$$\rho = 888\ \text{kg/m}^3$$
$$k = 0.145\ \text{W/m.°C}$$
$$C_p = 1880\ \text{J/kg.°C}$$
$$\text{Pr} = 2.08$$



Analysis The mass flow rate and the rate of heat transfer are

$$\dot{m} = \rho A_c \mathbf{V}_m = (888\ \text{kg/m}^3)\pi\frac{(0.03\ \text{m})^2}{4}(0.8\ \text{m/s}) = 0.5022\ \text{kg/s}$$

$$\dot{Q} = \dot{m}C_p(T_e - T_i) = (0.5022\ \text{kg/s})(1880\ \text{J/kg.°C})(30-10)\text{°C} = 18{,}881\ \text{W}$$

The Nusselt number is determined from Table 8-4 at D_i/D_o =3/5=0.6 to be Nu$_i$ = 5.564. Then the heat transfer coefficient, the hydraulic diameter of annulus, and the logarithmic mean temperature difference are

$$h_i = \frac{k}{D_h}Nu_i = \frac{0.145\ \text{W/m.°C}}{0.02\ \text{m}}(5.564) = 40.34\ \text{W/m}^2\text{.°C}$$

$$D_h = D_o - D_i = 0.05\ \text{m} - 0.03\ \text{m} = 0.02\ \text{m}$$

$$\Delta T_{\ln} = \frac{T_i - T_e}{\ln\left(\dfrac{T_s - T_e}{T_s - T_i}\right)} = \frac{10-30}{\ln\left(\dfrac{100-30}{100-10}\right)} = 79.58\text{°C}$$

The heat transfer surface area is determined from

$$\dot{Q} = hA_s\Delta T_{\ln} \longrightarrow A_s = \frac{\dot{Q}}{h\Delta T_{\ln}} = \frac{18{,}881\ \text{W}}{(40.34\ \text{W/m}^2\text{.°C})(79.58\text{°C})} = 5.881\ \text{m}^2$$

Then the tube length becomes

$$A_s = \pi DL \longrightarrow L = \frac{A_s}{\pi D_i} = \frac{5.881\ \text{m}^2}{\pi(0.03\ \text{m}^2)} = \mathbf{62.4\ m}$$

8-77 …. 8-79 Design and Essay Problems

8-79 A computer is cooled by a fan blowing air through the case of the computer. The flow rate of the fan and the diameter of the casing of the fan are to be specified.

Assumptions **1** Steady flow conditions exist. **2** Heat flux is uniformly distributed. **3** Air is an ideal gas with constant properties.

Properties The relevant properties of air are (Tables A-1 and A-15)

$$C_p = 1007 \text{ J/kg.°C}$$
$$R = 0.287 \text{ kPa.m}^3\text{/kg.K}$$

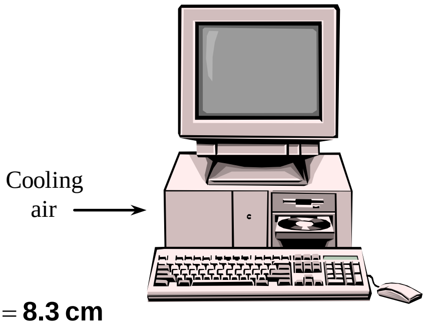
Analysis We need to determine the flow rate of air for the worst case scenario. Therefore, we assume the inlet temperature of air to be 50°C, the atmospheric pressure to be 70.12 kPa, and disregard any heat transfer from the outer surfaces of the computer case. The mass flow rate of air required to absorb heat at a rate of 80 W can be determined from

$$\dot{Q} = \dot{m}C_p(T_{out} - T_{in}) \longrightarrow \dot{m} = \frac{\dot{Q}}{C_p(T_{out} - T_{in})} = \frac{80 \text{ J/s}}{(1007 \text{ J/kg.°C})(60-50)\text{°C}} = 0.007944 \text{ kg/s}$$

In the worst case the exhaust fan will handle air at 60°C. Then the density of air entering the fan and the volume flow rate becomes

$$\rho = \frac{P}{RT} = \frac{70.12 \text{ kPa}}{(0.287 \text{ kPa.m}^3\text{/kg.K})(60+273)\text{K}} = 0.7337 \text{ kg/m}^3$$

$$\dot{V} = \frac{\dot{m}}{\rho} = \frac{0.007944 \text{ kg/s}}{0.7337 \text{ kg/m}^3} = 0.01083 \text{ m}^3\text{/s} = \mathbf{0.6497 \text{ m}^3\text{/min}}$$



For an average velocity of 120 m/min, the diameter of the duct in which the fan is installed can be determined from

$$\dot{V} = A_c V = \frac{\pi D^2}{4}V \longrightarrow D = \sqrt{\frac{4\dot{V}}{\pi V}} = \sqrt{\frac{4(0.6497 \text{ m}^3\text{/min})}{\pi(120 \text{ m/min})}} = 0.083 \text{ m} = \mathbf{8.3 \text{ cm}}$$

Chapter 9
NATURAL CONVECTION

Physical Mechanisms of Natural Convection

9-1C Natural convection is the mode of heat transfer that occurs between a solid and a fluid which moves under the influence of natural means. Natural convection differs from forced convection in that fluid motion in natural convection is caused by natural effects such as buoyancy.

9-2C The convection heat transfer coefficient is usually higher in forced convection because of the higher fluid velocities involved.

9-3C The hot boiled egg in a spacecraft will cool faster when the spacecraft is on the ground since there is no gravity in space, and thus there will be no natural convection currents which is due to the buoyancy force.

9-4C The upward force exerted by a fluid on a body completely or partially immersed in it is called the buoyancy or "lifting" force. The buoyancy force is proportional to the density of the medium. Therefore, the buoyancy force is the largest in mercury, followed by in water, air, and the evacuated chamber. Note that in an evacuated chamber there will be no buoyancy force because of absence of any fluid in the medium.

9-5C The buoyancy force is proportional to the density of the medium, and thus is larger in sea water than it is in fresh water. Therefore, the hull of a ship will sink deeper in fresh water because of the smaller buoyancy force acting upwards.

9-6C A spring scale measures the "weight" force acting on it, and the person will weigh less in water because of the upward buoyancy force acting on the person's body.

9-7C The greater the volume expansion coefficient, the greater the change in density with temperature, the greater the buoyancy force, and thus the greater the natural convection currents.

9-8C There cannot be any natural convection heat transfer in a medium that experiences no change in volume with temperature.

9-9C The lines on an interferometer photograph represent isotherms (constant temperature lines) for a gas, which correspond to the lines of constant density. Closely packed lines on a photograph represent a large temperature gradient.

9-10C The Grashof number represents the ratio of the buoyancy force to the viscous force acting on a fluid. The inertial forces in Reynolds number is replaced by the buoyancy forces in Grashof number.

9-11 The volume expansion coefficient is defined as $\beta = \frac{-1}{\rho}\left(\frac{\partial \rho}{\partial T}\right)_P$. For an ideal gas, $P = \rho RT$ or $\rho = \frac{P}{RT}$, and thus $\beta = -\frac{1}{\rho}\left(\frac{\partial (P/RT)}{\partial T}\right)_P = \frac{-1}{\rho}\left(\frac{-P}{RT^2}\right) = \frac{1}{\rho T}\left(\frac{P}{RT}\right) = \frac{1}{\rho T}(\rho) = \frac{1}{T}$

Natural Convection Over Surfaces

9-12C Rayleigh number is the product of the Grashof and Prandtl numbers.

9-13C A vertical cylinder can be treated as a vertical plate when $D \geq \frac{35L}{Gr^{1/4}}$.

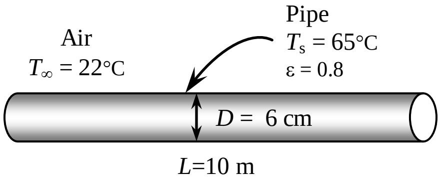
9-14C No, a hot surface will cool slower when facing down since the warmer air in this position cannot rise and escape easily.

9-15C The heat flux will be higher at the bottom of the plate since the thickness of the boundary layer which is a measure of thermal resistance is the lowest there.

9-16 A horizontal hot water pipe passes through a large room. The rate of heat loss from the pipe by natural convection and radiation is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** The temperature of the outer surface of the pipe is constant.

Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (65+22)/2 = 43.5$°C are (Table A-15)



$$k = 0.02688\ \text{W/m.°C}$$

$$\upsilon = 1.735\times10^{-5}\ \text{m}^2\text{/s}$$

$$\text{Pr} = 0.7245$$

$$\beta = \frac{1}{T_f} = \frac{1}{(43.5+273)\text{K}} = 0.00316\ \text{K}^{-1}$$

Analysis (*a*) The characteristic length in this case is the outer diameter of the pipe, $L_c = D = 0.06$ m. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)D^3}{\upsilon^2}\text{Pr} = \frac{(9.81\ \text{m/s}^2)(0.00316\ \text{K}^{-1})(65-22\ \text{K})(0.06\ \text{m})^3}{(1.735\times10^{-5}\ \text{m}^2\text{/s})^2}(0.7245) = 692{,}805$$

$$Nu = \left\{0.6 + \frac{0.387Ra^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6 + \frac{0.387(692{,}805)^{1/6}}{\left[1+(0.559/0.7245)^{9/16}\right]^{8/27}}\right\}^2 = 13.15$$

$$h = \frac{k}{D}Nu = \frac{0.02688\ \text{W/m.°C}}{0.06\ \text{m}}(13.15) = 5.893\ \text{W/m}^2\text{.°C}$$

$$A_s = \pi DL = \pi(0.06\ \text{m})(10\ \text{m}) = 1.885\ \text{m}^2$$

$$\dot{Q} = hA_s(T_s - T_\infty) = (5.893\ \text{W/m}^2\text{.°C})(1.885\ \text{m}^2)(65-22)\text{°C} = \mathbf{477.6\ W}$$

(*b*) The radiation heat loss from the pipe is

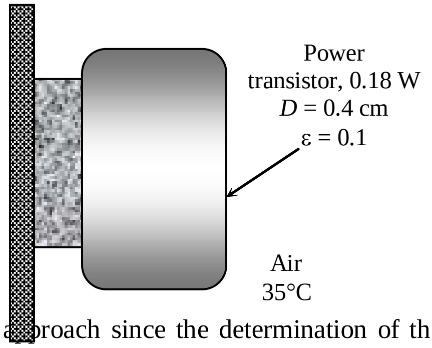
$$\dot{Q}_{rad} = \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4) = (0.8)(1.885\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\text{.K}^4)\left[(65+273\ \text{K})^4 - (22+273\ \text{K})^4\right] = \mathbf{468.4\ W}$$

9-17 A power transistor mounted on the wall dissipates 0.18 W. The surface temperature of the transistor is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** Any heat transfer from the base surface is disregarded. **4** The local atmospheric pressure is 1 atm. **5** Air properties are evaluated at 100°C.

Properties The properties of air at 1 atm and the given film temperature of 100°C are (Table A-15)

$$k = 0.03095 \text{ W/m.°C}$$
$$\upsilon = 2.306\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7111$$
$$\beta = \frac{1}{T_f} = \frac{1}{(100+273)\text{ K}} = 0.00268 \text{ K}^{-1}$$



Analysis The solution of this problem requires a trial-and-error approach since the determination of the Rayleigh number and thus the Nusselt number depends on the surface temperature which is unknown. We start the solution process by "guessing" the surface temperature to be 165°C for the evaluation of *h*. This is the surface temperature that will give a film temperature of 100°C. We will check the accuracy of this guess later and repeat the calculations if necessary.

The transistor loses heat through its cylindrical surface as well as its top surface. For convenience, we take the heat transfer coefficient at the top surface of the transistor to be the same as that of its side surface. (The alternative is to treat the top surface as a vertical plate, but this will double the amount of calculations without providing much improvement in accuracy since the area of the top surface is much smaller and it is circular in shape instead of being rectangular). The characteristic length in this case is the outer diameter of the transistor, $L_c = D = 0.004$ m. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)D^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.00268 \text{ K}^{-1})(165-35 \text{ K})(0.004 \text{ m})^3}{(2.306\times10^{-5} \text{ m}^2\text{/s})^2}(0.7111) = 292.6$$

$$Nu = \left\{0.6 + \frac{0.387 Ra^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6 + \frac{0.387(292.6)^{1/6}}{\left[1+(0.559/0.7111)^{9/16}\right]^{8/27}}\right\}^2 = 2.039$$

$$h = \frac{k}{D}Nu = \frac{0.03095 \text{ W/m.°C}}{0.004 \text{ m}}(2.039) = 15.78 \text{ W/m}^2\text{.°C}$$

$$A_s = \pi DL + \pi D^2/4 = \pi(0.004 \text{ m})(0.0045 \text{ m}) + \pi(0.004 \text{ m})^2/4 = 0.0000691 \text{ m}^2$$

and

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$
$$0.18 \text{ W} = (15.8 \text{ W/m}^2\text{.°C})(0.0000691 \text{ m}^2)(T_s - 35)\text{ °C}$$
$$+(0.1)(0.0000691 \text{ m}^2)(5.67\times10^{-8})\left[(T_s+273)^4 - (25+273 \text{ K})^4\right]$$
$$\longrightarrow T_s = 187\text{°C}$$

which is relatively close to the assumed value of 165°C. To improve the accuracy of the result, we repeat the Rayleigh number calculation at new surface temperature of 187°C and determine the surface temperature to be

T_s = **183°C**

Discussion W evaluated the air properties again at 100°C when repeating the calculation at the new surface temperature. It can be shown that the effect of this on the calculated surface temperature is less than 1°C.

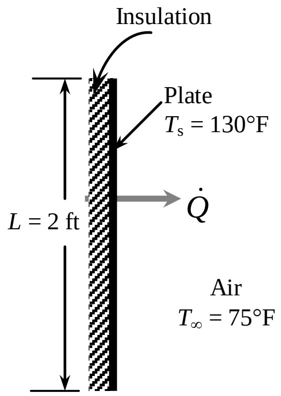
9-19E A hot plate with an insulated back is considered. The rate of heat loss by natural convection is to be determined for different orientations.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.



Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (130+75)/2 = 102.5$°F are (Table A-15)

$$k = 0.01535\ \text{Btu/h.ft.°F}$$
$$\upsilon = 0.1823\times10^{-3}\ \text{ft}^2/\text{s}$$
$$\text{Pr} = 0.7256$$
$$\beta = \frac{1}{T_f} = \frac{1}{(102.5+460)\text{R}} = 0.001778\ \text{R}^{-1}$$

Analysis (*a*) When the plate is vertical, the characteristic length is the height of the plate. $L_c = L = 2$ ft. Then,

$$Ra = \frac{g\beta(T_s-T_\infty)L^3}{\upsilon^2}\text{Pr} = \frac{(32.2\ \text{ft/s}^2)(0.001778\ \text{R}^{-1})(130-75\ \text{R})(2\ \text{ft})^3}{(0.1823\times10^{-3}\ \text{ft}^2/\text{s})^2}(0.7256) = 5.503\times10^8$$

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(5.503\times10^8)^{1/6}}{\left[1+\left(\frac{0.492}{0.7256}\right)^{9/16}\right]^{8/27}}\right\}^2 = 102.6$$

$$h = \frac{k}{L}Nu = \frac{0.01535\ \text{Btu/h.ft.°F}}{2\ \text{ft}}(102.6) = 0.7869\ \text{Btu/h.ft}^2.\text{°F}$$
$$A_s = L^2 = (2\ \text{ft})^2 = 4\ \text{ft}^2$$

and

$$\dot{Q} = hA_s(T_s-T_\infty) = (0.7869\ \text{Btu/h.ft}^2.\text{°F})(4\ \text{ft}^2)(130-75)\text{°C} = \mathbf{173.1\ Btu/h}$$

(*b*) When the plate is horizontal with hot surface facing up, the characteristic length is determined from

$$L_s = \frac{A_s}{P} = \frac{L^2}{4L} = \frac{L}{4} = \frac{2\ \text{ft}}{4} = 0.5\ \text{ft}\ .$$

Then,

$$Ra = \frac{g\beta(T_s-T_\infty)L_c^3}{\upsilon^2}\text{Pr} = \frac{(32.2\ \text{ft/s}^2)(0.001778\ \text{R}^{-1})(130-75\ \text{R})(0.5\ \text{ft})^3}{(0.1823\times10^{-3}\ \text{ft}^2/\text{s})^2}(0.7256) = 8.598\times10^6$$

$$Nu = 0.54Ra^{1/4} = 0.54(8.598\times10^6)^{1/4} = 29.24$$

$$h = \frac{k}{L_c}Nu = \frac{0.01535\ \text{Btu/h.ft.°F}}{0.5\ \text{ft}}(29.24) = 0.8975\ \text{Btu/h.ft}^2.\text{°F}$$

and

$$\dot{Q} = hA_s(T_s-T_\infty) = (0.8975\ \text{Btu/h.ft}^2.\text{°F})(4\ \text{ft}^2)(130-75)\text{°C} = \mathbf{197.4\ Btu/h}$$

(*c*) When the plate is horizontal with hot surface facing down, the characteristic length is again $\delta = 0.5$ ft and the Rayleigh number is $Ra = 8.598\times10^6$. Then,

$$Nu = 0.27Ra^{1/4^2} = 0.27(8.598\times10^6)^{1/4} = 14.62$$

$$h = \frac{k}{L_c}Nu = \frac{0.01535\ \text{Btu/h.ft.°F}}{0.5\ \text{ft}}(14.62) = 0.4487\ \text{Btu/h.ft}^2.\text{°F}$$

and

$$\dot{Q} = hA_s(T_s - T_\infty) = (0.4487\ \text{Btu/h.ft}^2.°\text{F})(4\ \text{ft}^2)(130 - 75)°\text{C} = \mathbf{98.7\ Btu/h}$$

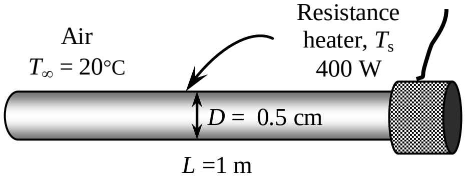
$$\Pr = 0.6986$$
$$\beta = \frac{1}{T_f} = \frac{1}{(500+273)\text{K}} = 0.001294 \text{ K}^{-1}$$



The properties of water at 40°C are

$$k = 0.631 \text{ W/m.°C}$$
$$\upsilon = \mu/\rho = 0.6582\times10^{-6} \text{ m}^2/\text{s}$$
$$\Pr = 4.32$$
$$\beta = 0.000377 \text{ K}^{-1}$$

Analysis (*a*) The solution of this problem requires a trial-and-error approach since the determination of the Rayleigh number and thus the Nusselt number depends on the surface temperature which is unknown. We start the solution process by "guessing" the surface temperature to be 1200°C for the calculation of *h*. We will check the accuracy of this guess later and repeat the calculations if necessary. The characteristic length in this case is the outer diameter of the wire, $L_c = D = 0.005$ m. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)D^3}{\upsilon^2}\Pr = \frac{(9.81 \text{ m/s}^2)(0.001294 \text{ K}^{-1})(1200-20)\text{°C}(0.005 \text{ m})^3}{(7.804\times10^{-5} \text{ m}^2/\text{s})^2}(0.6986) = 214.7$$

$$Nu = \left\{0.6 + \frac{0.387Ra^{1/6}}{\left[1+\left(0.559/\Pr\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6 + \frac{0.387(214.7)^{1/6}}{\left[1+\left(0.559/0.6986\right)^{9/16}\right]^{8/27}}\right\}^2 = 1.919$$

$$h = \frac{k}{D}Nu = \frac{0.05572 \text{ W/m.°C}}{0.005 \text{ m}}(1.919) = 21.38 \text{ W/m}^2.\text{°C}$$

$$A_s = \pi DL = \pi(0.005 \text{ m})(1 \text{ m}) = 0.01571 \text{ m}^2$$

and

$$\dot{Q} = hA_s(T_s - T_\infty)$$
$$400 \text{ W} = (21.38 \text{ W/m}^2.\text{°C})(0.01571 \text{ m}^2)(T_s - 20)\text{°C}$$
$$T_s = \mathbf{1211°C}$$

which is sufficiently close to the assumed value of 1200°C used in the evaluation of *h*, and thus it is not necessary to repeat calculations.

(*b*) For the case of water, we "guess" the surface temperature to be 40°C. The characteristic length in this case is the outer diameter of the wire, $L_c = D = 0.005$ m. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)D^3}{\upsilon^2}\Pr = \frac{(9.81 \text{ m/s}^2)(0.000377 \text{ K}^{-1})(40-20 \text{ K})(0.005 \text{ m})^3}{(0.6582\times10^{-6} \text{ m}^2/\text{s})^2}(4.32) = 92{,}197$$

$$Nu = \left\{0.6 + \frac{0.387Ra^{1/6}}{\left[1+\left(0.559/\Pr\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6 + \frac{0.387(92{,}197)^{1/6}}{\left[1+\left(0.559/4.32\right)^{9/16}\right]^{8/27}}\right\}^2 = 8.986$$

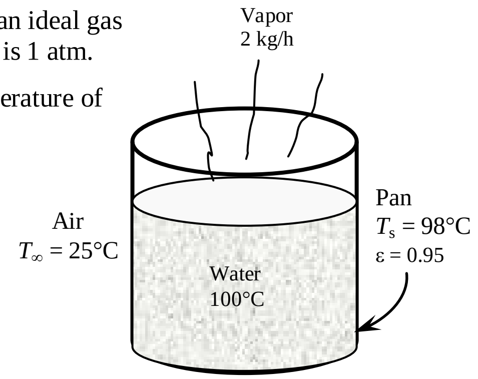
$$h = \frac{k}{D} Nu = \frac{0.631\,\text{W/m.°C}}{0.005\,\text{m}}(8.986) = 1134\,\text{W/m}^2\text{.°C}$$

and

$$\dot{Q} = hA_s(T_s - T_\infty)$$
$$400\,\text{W} = (1134\,\text{W/m}^2\text{.°C})(0.01571\,\text{m}^2)(T_s - 20)\text{°C}$$
$$T_s = \mathbf{42.5°C}$$

which is sufficiently close to the assumed value of 40°C in the evaluation of the properties and *h*. The film temperature in this case is $(T_s+T_\infty)/2$ = (42.5+20)/2 =31.3°C, which is close to the value of 40°C used in the evaluation of the properties.

9-22 Water is boiling in a pan that is placed on top of a stove. The rate of heat loss from the cylindrical side surface of the pan by natural convection and radiation and the ratio of heat lost from the side surfaces of the pan to that by the evaporation of water are to be determined.



Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (98+25)/2 = 61.5°C$ are (Table A-15)

$$k = 0.02819 \text{ W/m.°C}$$
$$\upsilon = 1.910 \times 10^{-5} \text{ m}^2/\text{s}$$
$$\text{Pr} = 0.7198$$
$$\beta = \frac{1}{T_f} = \frac{1}{(61.5+273)\text{K}} = 0.00299 \text{ K}^{-1}$$

Analysis (*a*) The characteristic length in this case is the height of the pan, $L_c = L = 0.12$ m. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.00299 \text{ K}^{-1})(98-25 \text{ K})(0.12 \text{ m})^3}{(1.910\times10^{-5} \text{ m}^2/\text{s})^2}(0.7198) = 7.299\times10^6$$

We can treat this vertical cylinder as a vertical plate since

$$\frac{35L}{Gr^{1/4}} = \frac{35(0.12)}{(7.299\times10^6/0.7198)^{1/4}} = 0.07443 < 0.25 \quad \text{and thus } D \geq \frac{35L}{Gr^{1/4}}$$

Therefore,

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(7.299\times10^6)^{1/6}}{\left[1+\left(\frac{0.492}{0.7198}\right)^{9/16}\right]^{8/27}}\right\}^2 = 28.60$$

$$h = \frac{k}{L}Nu = \frac{0.02819 \text{ W/m.°C}}{0.12 \text{ m}}(28.60) = 6.720 \text{ W/m}^2.\text{°C}$$
$$A_s = \pi DL = \pi(0.25 \text{ m})(0.12 \text{ m}) = 0.09425 \text{ m}^2$$

and

$$\dot{Q} = hA_s(T_s - T_\infty) = (6.720 \text{ W/m}^2.\text{°C})(0.09425 \text{ m}^2)(98-25)\text{°C} = \mathbf{46.2\ W}$$

(*b*) The radiation heat loss from the pan is

$$\dot{Q}_{rad} = \varepsilon A_s \sigma(T_s{}^4 - T_{surr}{}^4)$$
$$= (0.95)(0.09425 \text{ m}^2)(5.67\times10^{-8} \text{ W/m}^2.\text{K}^4)\left[(98+273 \text{ K})^4 - (25+273 \text{ K})^4\right] = \mathbf{56.1\ W}$$

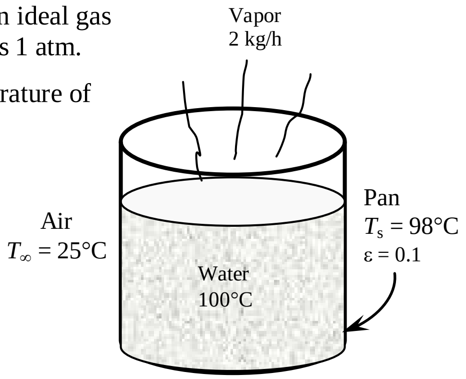
(*c*) The heat loss by the evaporation of water is

$$\dot{Q} = \dot{m}h_{fg} = (2/3600 \text{ kg/s})(2257 \text{ kJ/kg}) = 1.254 \text{ kW} = 1254 \text{ W}$$

Then the ratio of the heat lost from the side surfaces of the pan to that by the evaporation of water then becomes

$$f = \frac{46.2+56.1}{1254} = 0.082 = \mathbf{8.2\%}$$

9-23 Water is boiling in a pan that is placed on top of a stove. The rate of heat loss from the cylindrical side surface of the pan by natural convection and radiation and the ratio of heat lost from the side surfaces of the pan to that by the evaporation of water are to be determined.



Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (98+25)/2 = 61.5°\text{C}$ are (Table A-15)

$$k = 0.02819\ \text{W/m.°C}$$
$$\upsilon = 1.910\times10^{-5}\ \text{m}^2/\text{s}$$
$$\text{Pr} = 0.7198$$
$$\beta = \frac{1}{T_f} = \frac{1}{(61.5+273)\text{K}} = 0.00299\ \text{K}^{-1}$$

Analysis (*a*) The characteristic length in this case is the height of the pan, $L_c = L = 0.12$ m. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81\,\text{m/s}^2)(0.00299\,\text{K}^{-1})(98-25\,\text{K})(0.12\,\text{m})^3}{(1.910\times10^{-5}\ \text{m}^2/\text{s})^2}(0.7198) = 7.299\times10^6$$

We can treat this vertical cylinder as a vertical plate since

$$\frac{35L}{Gr^{1/4}} = \frac{35(0.12)}{(7.299\times10^6/0.7198)^{1/4}} = 0.07443 < 0.25 \quad \text{and thus } D \geq \frac{35L}{Gr^{1/4}}$$

Therefore,

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(7.299\times10^6)^{1/6}}{\left[1+\left(\frac{0.492}{0.7198}\right)^{9/16}\right]^{8/27}}\right\}^2 = 28.60$$

$$h = \frac{k}{L}Nu = \frac{0.02819\ \text{W/m.°C}}{0.12\ \text{m}}(28.60) = 6.720\ \text{W/m}^2.\text{°C}$$
$$A_s = \pi DL = \pi(0.25\,\text{m})(0.12\,\text{m}) = 0.09425\,\text{m}^2$$

and

$$\dot{Q} = hA_s(T_s - T_\infty) = (6.720\ \text{W/m}^2.\text{°C})(0.09425\,\text{m}^2)(98-25)\text{°C} = \mathbf{46.2\ W}$$

(b) The radiation heat loss from the pan is

$$\dot{Q}_{rad} = \varepsilon A_s \sigma(T_s{}^4 - T_{surr}{}^4)$$
$$= (0.10)(0.09425\,\text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)\left[(98+273\,\text{K})^4 - (25+273\,\text{K})^4\right] = \mathbf{5.9\ W}$$

(c) The heat loss by the evaporation of water is

$$\dot{Q} = \dot{m}h_{fg} = (2/3600\ \text{kg/s})(2257\ \text{kJ/kg}) = 1.254\ \text{kW} = 1254\ \text{W}$$

Then the ratio of the heat lost from the side surfaces of the pan to that by the evaporation of water then becomes

$$f = \frac{46.2+5.9}{1254} = 0.042 = \mathbf{4.2\%}$$

9-24 Some cans move slowly in a hot water container made of sheet metal. The rate of heat loss from the four side surfaces of the container and the annual cost of those heat losses are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **3** Heat loss from the top surface is disregarded.

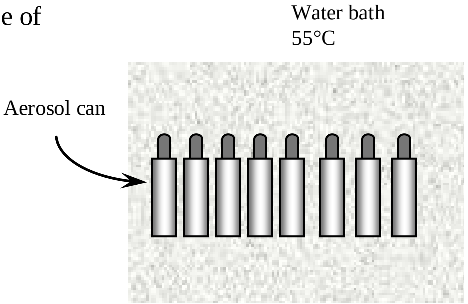
Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (55+20)/2 = 37.5°\text{C}$ are (Table A-15)

$$k = 0.02644 \text{ W/m.°C}$$

$$\upsilon = 1.678\times10^{-5} \text{ m}^2/\text{s}$$

$$\text{Pr} = 0.7261$$

$$\beta = \frac{1}{T_f} = \frac{1}{(37.5+273)\text{K}} = 0.003221 \text{ K}^{-1}$$



Analysis The characteristic length in this case is the height of the bath, $L_c = L = 0.5$ m. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.003221 \text{ K}^{-1})(55-20 \text{ K})(0.5 \text{ m})^3}{(1.678\times10^{-5} \text{ m}^2/\text{s})^2}(0.7261) = 3.565\times10^8$$

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(3.565\times10^8)^{1/6}}{\left[1+\left(\frac{0.492}{0.7261}\right)^{9/16}\right]^{8/27}}\right\}^2 = 89.84$$

$$h = \frac{k}{L}Nu = \frac{0.02644 \text{ W/m.°C}}{0.5 \text{ m}}(89.84) = 4.75 \text{ W/m}^2.\text{°C}$$

$$A_s = 2[(0.5 \text{ m})(1 \text{ m}) + (0.5 \text{ m})(3.5 \text{ m})] = 4.5 \text{ m}^2$$

and

$$\dot{Q} = hA_s(T_s - T_\infty) = (4.75 \text{ W/m}^2.\text{°C})(4.5 \text{ m}^2)(55-20)\text{°C} = 748.1 \text{ W}$$

The radiation heat loss is

$$\begin{aligned}\dot{Q}_{rad} &= \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4) \\ &= (0.7)(4.5 \text{ m}^2)(5.67\times10^{-8} \text{ W/m}^2.\text{K}^4)\left[(55+273 \text{ K})^4 - (20+273 \text{ K})^4\right] = 750.9 \text{ W}\end{aligned}$$

Then the total rate of heat loss becomes

$$\dot{Q}_{total} = \dot{Q}_{\substack{natural\\convection}} + \dot{Q}_{rad} = 748.1 + 750.9 = \mathbf{1499\ W}$$

The amount and cost of the heat loss during one year is

$$Q_{total} = \dot{Q}_{total}\Delta t = (1.499 \text{ kW})(8760 \text{ h}) = 13{,}131 \text{ kWh}$$

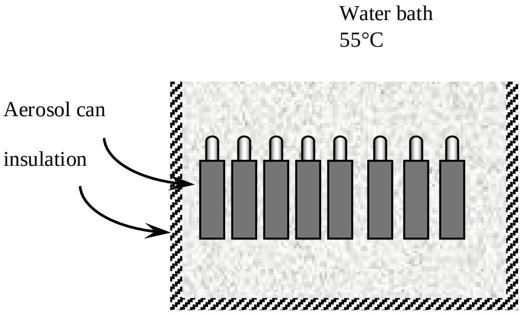
$$\text{Cost} = (13{,}131 \text{ kWh})(\$0.085/\text{kWh}) = \mathbf{\$1116}$$

9-25 Some cans move slowly in a hot water container made of sheet metal. It is proposed to insulate the side and bottom surfaces of the container for \$350. The simple payback period of the insulation to pay for itself from the energy it saves is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **3** Heat loss from the top surface is disregarded.

Properties Insulation will drop the outer surface temperature to a value close to the ambient temperature. The solution of this problem requires a trial-and-error approach since the determination of the Rayleigh number and thus the Nusselt number depends on the surface temperature, which is unknown. We assume the surface temperature to be 26°C. The properties of air at the anticipated film temperature of (26+20)/2=23°C are (Table A-15)

$$k = 0.02536 \text{ W/m.°C}$$
$$\upsilon = 1.543\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7301$$
$$\beta = \frac{1}{T_f} = \frac{1}{(23+273)\text{K}} = 0.00338 \text{ K}^{-1}$$



Analysis We start the solution process by "guessing" the outer surface temperature to be 26 °C. We will check the accuracy of this guess later and repeat the calculations if necessary with a better guess based on the results obtained. The characteristic length in this case is the height of the tank, $L_c = L = 0.5$ m. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.00338 \text{ K}^{-1})(26-20 \text{ K})(0.5 \text{ m})^3}{(1.543\times10^{-5} \text{ m}^2\text{/s})^2}(0.7301) = 7.622\times10^7$$

$$\text{Nu} = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(7.622\times10^7)^{1/6}}{\left[1+\left(\frac{0.492}{0.7301}\right)^{9/16}\right]^{8/27}}\right\}^2 = 56.53$$

$$h = \frac{k}{L}Nu = \frac{0.02536 \text{ W/m.°C}}{0.5 \text{ m}}(56.53) = 2.868 \text{ W/m}^2\text{.°C}$$
$$A_s = 2[(0.5 \text{ m})(1.10 \text{ m}) + (0.5 \text{ m})(3.60 \text{ m})] = 4.7 \text{ m}^2$$

Then the total rate of heat loss from the outer surface of the insulated tank by convection and radiation becomes

$$\begin{aligned}\dot{Q} = \dot{Q}_{conv} + \dot{Q}_{rad} &= hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)\\ &= (2.868 \text{ W/m}^2\text{.°C})(4.7 \text{ m}^2)(26-20)\text{°C}\\ &\quad + (0.1)(4.7 \text{ m}^2)(5.67\times10^{-8} \text{ W/m}^2\text{.K}^4)[(26+273 \text{ K})^4 - (20+273 \text{ K})^4]\\ &= 97.5 \text{ W}\end{aligned}$$

In steady operation, the heat lost by the side surfaces of the tank must be equal to the heat lost from the exposed surface of the insulation by convection and radiation, which must be equal to the heat conducted through the insulation. The second conditions requires the surface temperature to be

$$\dot{Q} = \dot{Q}_{insulation} = kA_s\frac{T_{\text{tank}} - T_s}{L} \rightarrow 97.5 \text{ W} = (0.035 \text{ W/m.°C})(4.7 \text{ m}^2)\frac{(55-T_s)\text{°C}}{0.05 \text{ m}}$$

It gives T_s = 25.38°C, which is very close to the assumed temperature, 26°C. Therefore, there is no need to repeat the calculations.

The total amount of heat loss and its cost during one year are

$$Q_{total} = \dot{Q}_{total}\Delta t = (97.5 \text{ W})(8760 \text{ h}) = 853.7 \text{ kWh}$$

$$\text{Cost} = (853.7\ \text{kWh})(\$0.085/\text{kWh}) = \$72.6$$

Then money saved during a one-year period due to insulation becomes

$$\text{Money saved} = \text{Cost}_{\substack{\textit{without}\\ \textit{insulation}}} - \text{Cost}_{\substack{\textit{with}\\ \textit{insulation}}} = \$1116 - \$72.6 = \$1043$$

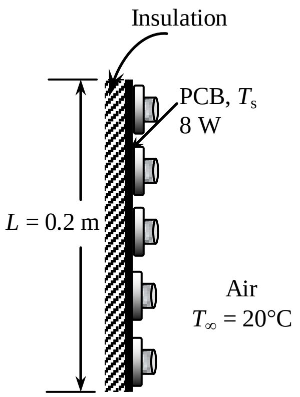
where $1116 is obtained from the solution of Problem 9-24.

The insulation will pay for itself in

$$\text{Payback period} = \frac{\text{Cost}}{\text{Money saved}} = \frac{\$350}{\$1043/\mathit{yr}} = \mathbf{0.3354\ yr = 122\ days}$$

Discussion We would definitely recommend the installation of insulation in this case.

9-26 A printed circuit board (PCB) is placed in a room. The average temperature of the hot surface of the board is to be determined for different orientations.



Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **3** The heat loss from the back surface of the board is negligible.

Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2 = (45+20)/2 = 32.5$°C are (Table A-15)

$$k = 0.02607 \text{ W/m.°C}$$
$$\upsilon = 1.631\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7275$$
$$\beta = \frac{1}{T_f} = \frac{1}{(32.5+273)\text{K}} = 0.003273 \text{ K}^{-1}$$

Analysis The solution of this problem requires a trial-and-error approach since the determination of the Rayleigh number and thus the Nusselt number depends on the surface temperature which is unknown

(*a*) **Vertical PCB** . We start the solution process by "guessing" the surface temperature to be 45°C for the evaluation of the properties and *h*. We will check the accuracy of this guess later and repeat the calculations if necessary. The characteristic length in this case is the height of the PCB, $L_c = L = 0.2$ m. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.003273 \text{ K}^{-1})(45-20 \text{ K})(0.2 \text{ m})^3}{(1.631\times10^{-5} \text{ m}^2\text{/s})^2}(0.7275) = 1.756\times10^7$$

$$\text{Nu} = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(1.756\times10^7)^{1/6}}{\left[1+\left(\frac{0.492}{0.7275}\right)^{9/16}\right]^{8/27}}\right\}^2 = 36.78$$

$$h = \frac{k}{L}Nu = \frac{0.02607 \text{ W/m.°C}}{0.2 \text{ m}}(36.78) = 4.794 \text{ W/m}^2\text{.°C}$$
$$A_s = (0.15 \text{ m})(0.2 \text{ m}) = 0.03 \text{ m}^2$$

Heat loss by both natural convection and radiation heat can be expressed as

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$
$$8 \text{ W} = (4.794 \text{ W/m}^2\text{.°C})(0.03 \text{ m}^2)(T_s - 20)\text{°C} + (0.8)(0.03 \text{ m}^2)(5.67\times10^{-8})\left[(T_s+273)^4 - (20+273 \text{ K})^4\right]$$

Its solution is

$$T_s = \mathbf{46.6°\,C}$$

which is sufficiently close to the assumed value of 45°C for the evaluation of the properties and *h*.

(*b*) **Horizontal, hot surface facing up** Again we assume the surface temperature to be 45 °C and use the properties evaluated above. The characteristic length in this case is

$$L_c = \frac{A_s}{p} = \frac{(0.20 \text{ m})(0.15 \text{ m})}{2(0.2 \text{ m} + 0.15 \text{ m})} = 0.0429 \text{ m}.$$

Then,

$$Ra = \frac{g\beta(T_s - T_\infty)L_c^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.003273 \text{ K}^{-1})(45-20 \text{ K})(0.0429 \text{ m})^3}{(1.631\times10^{-5} \text{ m}^2\text{/s})^2}(0.7275) = 1.728\times10^5$$

$$Nu = 0.54Ra^{1/4} = 0.54(1.728\times10^5)^{1/4} = 11.01$$

$$h = \frac{k}{L_c}Nu = \frac{0.02607 \text{ W/m.°C}}{0.0429 \text{ m}}(11.01) = 6.696 \text{ W/m}^2\text{.°C}$$

Heat loss by both natural convection and radiation heat can be expressed as

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A_s \sigma(T_s{}^4 - T_{surr}{}^4)$$

$$8\text{ W} = (6.696\text{ W/m}^2.°\text{C})(0.03\text{ m}^2)(T_s - 20)°\text{C} + (0.8)(0.03\text{ m}^2)(5.67\times10^{-8})[(T_s + 273)^4 - (20 + 273\text{ K})^4]$$

Its solution is

$$T_s = \mathbf{42.6°C}$$

which is sufficiently close to the assumed value of 45°C in the evaluation of the properties and *h*.

(c) **Horizontal, hot surface facing down** This time we expect the surface temperature to be higher, and assume the surface temperature to be 50 °C. We will check this assumption after obtaining result and repeat calculations with a better assumption, if necessary. The properties of air at the film temperature of

$T_f = \dfrac{T_s + T_\infty}{2} = \dfrac{50 + 20}{2} = 35°\text{C}$ are (Table A-15)

$$k = 0.02625\text{ W/m.°C}$$

$$\upsilon = 1.655\times10^{-5}\text{ m}^2\text{/s}$$

$$\Pr = 0.7268$$

$$\beta = \frac{1}{T_f} = \frac{1}{(35 + 273)\text{K}} = 0.003247\text{ K}^{-1}$$

The characteristic length in this case is, from part (b), L_c = 0.0429 m. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)L_c^3}{\upsilon^2}\Pr = \frac{(9.81\text{ m/s}^2)(0.003247\text{ K}^{-1})(50 - 20\text{ K})(0.0429\text{ m})^3}{(1.655\times10^{-5}\text{ m}^2\text{/s})^2}(0.7268) = 166{,}379$$

$$Nu = 0.27Ra^{1/4} = 0.27(166{,}379)^{1/4} = 5.453$$

$$h = \frac{k}{L_c}Nu = \frac{0.02625\text{ W/m.°C}}{0.0429\text{ m}}(5.453) = 3.340\text{ W/m}^2.°\text{C}$$

Considering both natural convection and radiation heat loses

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A_s \sigma(T_s{}^4 - T_{surr}{}^4)$$

$$8\text{ W} = (3.340\text{ W/m}^2.°\text{C})(0.03\text{ m}^2)(T_s - 20)°\text{C} + (0.8)(0.03\text{ m}^2)(5.67\times10^{-8})[(T_s + 273)^4 - (20 + 273\text{ K})^4]$$

Its solution is

$$T_s = \mathbf{50.7°C}$$

which is very close to the assumed value. Therefore, there is no need to repeat calculations.

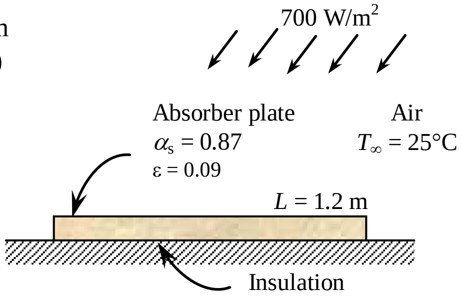
9-28 Absorber plates whose back side is heavily insulated is placed horizontally outdoors. Solar radiation is incident on the plate. The equilibrium temperature of the plate is to be determined for two cases.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2 = (115+25)/2 = 70°\text{C}$ are (Table A-15)



$$k = 0.02881\ \text{W/m.°C}$$

$$\upsilon = 1.995\times10^{-5}\ \text{m}^2/\text{s}$$

$$\text{Pr} = 0.7177$$

$$\beta = \frac{1}{T_f} = \frac{1}{(70+273)\text{K}} = 0.002915\ \text{K}^{-1}$$

Analysis The solution of this problem requires a trial-and-error approach since the determination of the Rayleigh number and thus the Nusselt number depends on the surface temperature which is unknown. We start the solution process by "guessing" the surface temperature to be 115°C for the evaluation of the properties and *h*. We will check the accuracy of this guess later and repeat the calculations if necessary. The characteristic length in this case is $L_c = \frac{A_s}{p} = \frac{(1.2\ \text{m})(0.8\ \text{m})}{2(1.2\ \text{m}+0.8\ \text{m})} = 0.24\ \text{m}.$ Then,

$$Ra = \frac{g\beta(T_s-T_\infty)L_c^3}{\upsilon^2}\text{Pr} = \frac{(9.81\ \text{m/s}^2)(0.002915\ \text{K}^{-1})(115-25\ \text{K})(0.24\ \text{m})^3}{(1.995\times10^{-5}\ \text{m}^2/\text{s})^2}(0.7177) = 6.414\times10^7$$

$$Nu = 0.54Ra^{1/4} = 0.54(6.414\times10^7)^{1/4} = 48.33$$

$$h = \frac{k}{L_c}Nu = \frac{0.02881\ \text{W/m.°C}}{0.24\ \text{m}}(48.33) = 5.801\ \text{W/m}^2.°\text{C}$$

$$A_s = (0.8\ \text{m})(1.2\ \text{m}) = 0.96\ \text{m}^2$$

In steady operation, the heat gain by the plate by absorption of solar radiation must be equal to the heat loss by natural convection and radiation. Therefore,

$$\dot{Q} = \alpha\dot{q}A_s = (0.87)(700\ \text{W/m}^2)(0.96\ \text{m}^2) = 584.6\ \text{W}$$

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s{}^4 - T_{sky}{}^4)$$

$$584.6\ \text{W} = (5.801\ \text{W/m}^2.°\text{C})(0.96\ \text{m}^2)(T_s-25)°\text{C} + (0.09)(0.96\ \text{m}^2)(5.67\times10^{-8})[(T_s+273)^4 - (10+273\ \text{K})^4]$$

Its solution is $T_s = \mathbf{115.6°C}$

which is identical to the assumed value. Therefore there is no need to repeat calculations.

If the absorber plate is made of ordinary aluminum which has a solar absorptivity of 0.28 and an emissivity of 0.07, the rate of solar gain becomes

$$\dot{Q} = \alpha\dot{q}A_s = (0.28)(700\ \text{W/m}^2)(0.96\ \text{m}^2) = 188.2\ \text{W}$$

Again noting that in steady operation the heat gain by the plate by absorption of solar radiation must be equal to the heat loss by natural convection and radiation, and using the convection coefficient determined above for convenience,

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s{}^4 - T_{sky}{}^4)$$

$$188.2\ \text{W} = (5.801\ \text{W/m}^2.°\text{C})(0.96\ \text{m}^2)(T_s-25)°\text{C} + (0.07)(0.96\ \text{m}^2)(5.67\times10^{-8})[(T_s+273)^4 - (10+273\ \text{K})^4]$$

Its solution is T_s = **55.2°C**

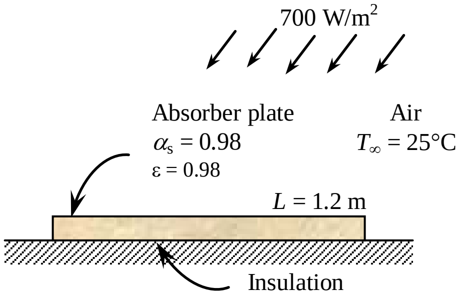
Repeating the calculations at the new film temperature of 40°C, we obtain

h = 4.524 W/m².°C and T_s = **62.8°C**

9-29 An absorber plate whose back side is heavily insulated is placed horizontally outdoors. Solar radiation is incident on the plate. The equilibrium temperature of the plate is to be determined for two cases.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2 = (70+25)/2 = 47.5°\text{C}$ are (Table A-15)



$$k = 0.02717 \text{ W/m.°C}$$
$$\upsilon = 1.774\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7235$$
$$\beta = \frac{1}{T_f} = \frac{1}{(47.5+273)\text{K}} = 0.00312 \text{ K}^{-1}$$

Analysis The solution of this problem requires a trial-and-error approach since the determination of the Rayleigh number and thus the Nusselt number depends on the surface temperature which is unknown. We start the solution process by "guessing" the surface temperature to be 70°C for the evaluation of the properties and *h*. We will check the accuracy of this guess later and repeat the calculations if necessary. The characteristic length in this case is $L_c = \frac{A_s}{p} = \frac{(1.2\text{ m})(0.8\text{ m})}{2(1.2\text{ m}+0.8\text{ m})} = 0.24\text{ m}$. Then,

$$Ra = \frac{g\beta(T_s-T_\infty)L_c^3}{\upsilon^2}\text{Pr} = \frac{(9.81\text{ m/s}^2)(0.00312\text{ K}^{-1})(70-25\text{ K})(0.24\text{ m})^3}{(1.774\times10^{-5}\text{ m}^2\text{/s})^2}(0.7235) = 4.379\times10^7$$

$$Nu = 0.54Ra^{1/4} = 0.54(4.379\times10^7)^{1/4} = 43.93$$

$$h = \frac{k}{L_c}Nu = \frac{0.02717\text{ W/m.°C}}{0.24\text{ m}}(43.93) = 4.973\text{ W/m}^2\text{.°C}$$

$$A_s = (0.8\text{ m})(1.2\text{ m}) = 0.96\text{ m}^2$$

In steady operation, the heat gain by the plate by absorption of solar radiation must be equal to the heat loss by natural convection and radiation. Therefore,

$$\dot{Q} = \alpha\dot{q}A_s = (0.98)(700\text{ W/m}^2)(0.96\text{ m}^2) = 658.6\text{ W}$$

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$

$$658.6\text{ W} = (4.973\text{ W/m}^2\text{.°C})(0.96\text{ m}^2)(T_s-25)\text{°C} + (0.98)(0.96\text{ m}^2)(5.67\times10^{-8})[(T_s+273)^4 - (10+273\text{ K})^4]$$

Its solution is $T_s = \mathbf{73.5°C}$

which is close to the assumed value. Therefore there is no need to repeat calculations.

For a white painted absorber plate, the solar absorptivity is 0.26 and the emissivity is 0.90. Then the rate of solar gain becomes

$$\dot{Q} = \alpha\dot{q}A_s = (0.26)(700\text{ W/m}^2)(0.96\text{ m}^2) = 174.7\text{ W}$$

Again noting that in steady operation the heat gain by the plate by absorption of solar radiation must be equal to the heat loss by natural convection and radiation, and using the convection coefficient determined above for convenience (actually, we should calculate the new *h* using data at a lower temperature, and iterating if necessary for better accuracy),

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$

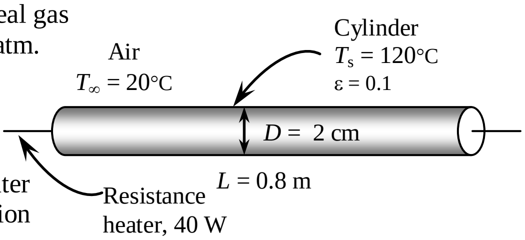
$$174.7\text{ W} = (4.973\text{ W/m}^2\text{.°C})(0.96\text{ m}^2)(T_s-25)\text{°C} + (0.90)(0.96\text{ m}^2)(5.67\times10^{-8})[(T_s+273)^4 - (10+273\text{ K})^4]$$

Its solution is $T_s = \mathbf{35.0°C}$

Discussion If we recalculated the *h* using air properties at 30°C, we would obtain

$h = 3.47\text{ W/m}^2\text{.°C}$ and $T_s = 36.6°\text{C}$.

9-30 A resistance heater is placed along the centerline of a horizontal cylinder whose two circular side surfaces are well insulated. The natural convection heat transfer coefficient and whether the radiation effect is negligible are to be determined.



Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

Analysis The heat transfer surface area of the cylinder is

$$A = \pi DL = \pi(0.02\text{ m})(0.8\text{ m}) = 0.05027\text{ m}^2$$

Noting that in steady operation the heat dissipated from the outer surface must equal to the electric power consumed, and radiation is negligible, the convection heat transfer is determined to be

$$\dot{Q} = hA_s(T_s - T_\infty) \rightarrow \; h = \frac{\dot{Q}}{A_s(T_s - T_\infty)} = \frac{40\text{ W}}{(0.05027\text{ m}^2)(120-20)°\text{C}} = \mathbf{7.96\ W/m^2.°C}$$

The radiation heat loss from the cylinder is

$$\begin{aligned}\dot{Q}_{rad} &= \varepsilon A_s \sigma (T_s{}^4 - T_{surr}{}^4) \\ &= (0.1)(0.05027\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2.\text{K}^4)[(120+273\text{ K})^4 - (20+273\text{ K})^4] = 4.7\text{ W}\end{aligned}$$

Therefore, the fraction of heat loss by radiation is

$$\text{Radiation fraction} = \frac{\dot{Q}_{radiation}}{\dot{Q}_{total}} = \frac{4.7\text{ W}}{40\text{ W}} = 0.1175 = 11.8\%$$

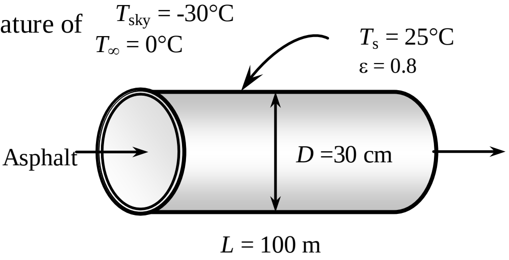
which is greater than 5%. Therefore, the radiation effect is still more than acceptable, and corrections must be made for the radiation effect.

9-31 A thick fluid flows through a pipe in calm ambient air. The pipe is heated electrically. The power rating of the electric resistance heater and the cost of electricity during a 10-h period are to be determined.√

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (25+0)/2 = 12.5$°C are (Table A-15)

$$k = 0.02458 \text{ W/m.°C}$$
$$\upsilon = 1.448\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7330$$
$$\beta = \frac{1}{T_f} = \frac{1}{(12.5+273)\text{K}} = 0.003503 \text{ K}^{-1}$$



Analysis The characteristic length in this case is the outer diameter of the pipe, $L_c = D = 0.3$ m. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)L_c^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.003503 \text{ K}^{-1})(25-0 \text{ K})(0.3 \text{ m})^3}{(1.448\times10^{-5} \text{ m}^2\text{/s})^2}(0.7330) = 8.106\times10^7$$

$$Nu = \left\{0.6 + \frac{0.387Ra^{1/6}}{\left[1+\left(0.559/\text{Pr}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6 + \frac{0.387(8.106\times10^7)^{1/6}}{\left[1+\left(0.559/0.7330\right)^{9/16}\right]^{8/27}}\right\}^2 = 53.29$$

$$h = \frac{k}{L_c}Nu = \frac{0.02458 \text{ W/m.°C}}{0.3 \text{ m}}(53.29) = 4.366 \text{ W/m}^2\text{.°C}$$

$$A_s = \pi DL = \pi(0.3 \text{ m})(100 \text{ m}) = 94.25 \text{ m}^2$$

and

$$\dot{Q} = hA_s(T_s - T_\infty) = (4.366 \text{ W/m}^2\text{.°C})(94.25 \text{ m}^2)(25-0)\text{°C} = 10{,}287 \text{ W}$$

The radiation heat loss from the cylinder is

$$\begin{aligned}\dot{Q}_{rad} &= \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)\\ &= (0.8)(94.25 \text{ m}^2)(5.67\times10^{-8} \text{ W/m}^2\text{.K}^4)[(25+273 \text{ K})^4 - (-30+273 \text{ K})^4] = 18{,}808 \text{ W}\end{aligned}$$

Then,

$$\dot{Q}_{total} = \dot{Q}_{\substack{natural\\ convection}} + \dot{Q}_{radiation} = 10{,}287 + 18{,}808 = 29{,}094 \text{ W} = \mathbf{29.1\ kW}$$

The total amount and cost of heat loss during a 10 hour period is

$$Q = \dot{Q}\Delta t = (29.1 \text{ kW})(10 \text{ h}) = 290.9 \text{ kWh}$$

$$\text{Cost} = (290.9 \text{ kWh})(\$0.09/\text{kWh}) = \mathbf{\$26.18}$$

9-32 A fluid flows through a pipe in calm ambient air. The pipe is heated electrically. The thickness of the insulation needed to reduce the losses by 85% and the money saved during 10-h are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

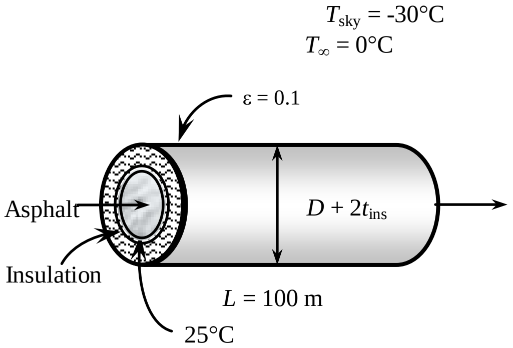
Properties Insulation will drop the outer surface temperature to a value close to the ambient temperature, and possible below it because of the very low sky temperature for radiation heat loss. For convenience, we use the properties of air at 1 atm and 5°C (the anticipated film temperature) (Table A-15),

$$k = 0.02401\,\text{W/m.°C}$$

$$\upsilon = 1.382\times10^{-5}\ \text{m}^2/\text{s}$$

$$\text{Pr} = 0.7350$$

$$\beta = \frac{1}{T_f} = \frac{1}{(5+273)\text{K}} = 0.003597\ \text{K}^{-1}$$



Analysis The rate of heat loss in the previous problem was obtained to be 29,094 W. Noting that insulation will cut down the heat losses by 85%, the rate of heat loss will be

$$\dot{Q} = (1-0.85)\dot{Q}_{\text{no insulation}} = 0.15\times 29{,}094\ \text{W} = 4364\ \text{W}$$

The amount of energy and money insulation will save during a 10-h period is simply determined from

$$Q_{saved,total} = \dot{Q}_{saved}\Delta t = (0.85\times 29.094\ \text{kW})(10\ \text{h}) = 247.3\,\text{kWh}$$

$$\text{Money saved} = (\text{Energy saved})(\text{Unit cost of energy}) = (247.3\,\text{kWh})(\$0.09/\text{kWh}) = \mathbf{\$22.26}$$

The characteristic length in this case is the outer diameter of the insulated pipe, $L_c = D + 2t_{insul} = 0.3 + 2t_{insul}$ where t_{insul} is the thickness of insulation in m. Then the problem can be formulated for T_s and t_{insul} as follows:

$$Ra = \frac{g\beta(T_s - T_\infty)L_c^3}{\upsilon^2}\text{Pr} = \frac{(9.81\,\text{m/s}^2)(0.003597\ \text{K}^{-1})[(T_s-273)\text{K}](0.3+2t_{insul})^3}{(1.382\times10^{-5}\ \text{m}^2/\text{s})^2}(0.7350)$$

$$Nu = \left\{0.6 + \frac{0.387Ra^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6 + \frac{0.387Ra^{1/6}}{\left[1+(0.559/0.7350)^{9/16}\right]^{8/27}}\right\}^2$$

$$h = \frac{k}{L_c}Nu = \frac{0.02401\,\text{W/m.°C}}{L_c}Nu$$

$$A_s = \pi D_0 L = \pi(0.3+2t_{insul})(100\,\text{m})$$

The total rate of heat loss from the outer surface of the insulated pipe by convection and radiation becomes

$$\dot{Q} = \dot{Q}_{conv} + \dot{Q}_{rad} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$

$$4364 = hA_s(T_s - 273) + (0.1)A_s(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)[T_s^4 - (-30+273\,\text{K})^4]$$

In steady operation, the heat lost by the side surfaces of the pipe must be equal to the heat lost from the exposed surface of the insulation by convection and radiation, which must be equal to the heat conducted through the insulation. Therefore,

$$\dot{Q} = \dot{Q}_{insulation} = \frac{2\pi kL(T_{\text{tank}} - T_s)}{\ln(D_o/D)} \rightarrow 4364\ \text{W} = \frac{2\pi(0.035\,\text{W/m.°C})(100\,\text{m})(298-T_s)\text{K}}{\ln[(0.3+2t_{insul})/0.3]}$$

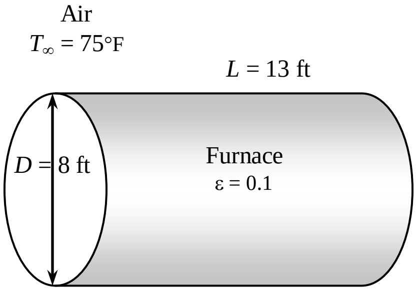
The solution of all of the equations above simultaneously using an equation solver gives T_s = 281.5 K = 8.5°C and t_{insul} = **0.013 m = 1.3 cm**.

Note that the film temperature is (8.5+0)/2 = 4.25°C which is very close to the assumed value of 5°C. Therefore, there is no need to repeat the calculations using properties at this new film temperature.

9-33E An industrial furnace that resembles a horizontal cylindrical enclosure whose end surfaces are well insulated. The highest allowable surface temperature of the furnace and the annual cost of this loss to the plant are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2=(140+75)/2=107.5$°F are (Table A-15)



$$k = 0.01546 \text{ Btu/h.ft.°F}$$
$$\upsilon = 0.1851\times10^{-3} \text{ ft}^2\text{/s}$$
$$\text{Pr} = 0.7249$$
$$\beta = \frac{1}{T_f} = \frac{1}{(107.5+460)\text{R}} = 0.001762 \text{ R}^{-1}$$

Analysis The solution of this problem requires a trial-and-error approach since the determination of the Rayleigh number and thus the Nusselt number depends on the surface temperature which is unknown. We start the solution process by "guessing" the surface temperature to be 140°F for the evaluation of the properties and h. We will check the accuracy of this guess later and repeat the calculations if necessary. The characteristic length in this case is the outer diameter of the furnace, $L_c = D = 8$ ft. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)D^3}{\upsilon^2}\text{Pr} = \frac{(32.2 \text{ ft/s}^2)(0.001762 \text{ R}^{-1})(140-75 \text{ R})(8 \text{ ft})^3}{(0.1851\times10^{-3} \text{ ft}^2\text{/s})^2}(0.7249) = 3.996\times10^{10}$$

$$Nu = \left\{0.6 + \frac{0.387Ra^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6 + \frac{0.387(3.996\times10^{10})^{1/6}}{\left[1+(0.559/0.7249)^{9/16}\right]^{8/27}}\right\}^2 = 376.9$$

$$h = \frac{k}{D}Nu = \frac{0.01546 \text{ Btu/h.ft.°F}}{8 \text{ ft}}(376.9) = 0.7287 \text{ Btu/h.ft}^2\text{.°F}$$

$$A_s = \pi DL = \pi(8 \text{ ft})(13 \text{ ft}) = 326.7 \text{ ft}^2$$

The total rate of heat generated in the furnace is

$$\dot{Q}_{gen} = (0.82)(48 \text{ therms/h})(100{,}000 \text{ Btu/therm}) = 3.936\times10^6 \text{ Btu/h}$$

Noting that 1% of the heat generated can be dissipated by natural convection and radiation ,

$$\dot{Q} = (0.01)(3.936\times10^6 \text{ Btu/h}) = 39{,}360 \text{ Btu/h}$$

The total rate of heat loss from the furnace by natural convection and radiation can be expressed as

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$

$$39{,}360 \text{ Btu/h} = (0.7287 \text{ Btu/h.ft}^2\text{.°F})(326.7 \text{ ft}^2)[T_s - (75+460 \text{ R})]$$
$$+(0.85)(326.7 \text{ m}^2)(0.1714\times10^{-8} \text{ Btu/h.ft}^2\text{.R}^4)[T_s{}^4 - (75+460 \text{ R})^4]$$

Its solution is

$$T_s = 601.8 \text{ R} = \mathbf{141.8°F}$$

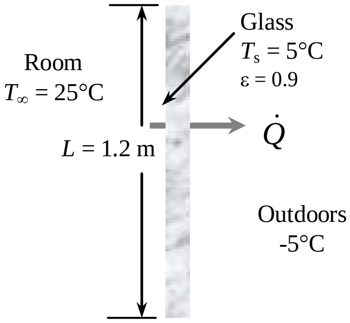
which is very close to the assumed value. Therefore, there is no need to repeat calculations.

The total amount of heat loss and its cost during a-2800 hour period is

$$Q_{total} = \dot{Q}_{total}\Delta t = (39{,}360 \text{ Btu/h})(2800 \text{ h}) = 1.102\times10^8 \text{ Btu}$$

$$\text{Cost} = (1.102\times10^8/100{,}000 \text{ therm})(\$0.65/\text{therm}) = \mathbf{\$716.4}$$

9-34 A glass window is considered. The convection heat transfer coefficient on the inner side of the window, the rate of total heat transfer through the window, and the combined natural convection and radiation heat transfer coefficient on the outer surface of the window are to be determined.



Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (5+25)/2 = 15°C$ are (Table A-15)

$$k = 0.02476 \text{ W/m.°C}$$
$$\upsilon = 1.471\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7323$$
$$\beta = \frac{1}{T_f} = \frac{1}{(15+273)\text{K}} = 0.003472 \text{ K}^{-1}$$

Analysis (*a*) The characteristic length in this case is the height of the window, $L_c = L = 1.2$ m. Then,

$$Ra = \frac{g\beta(T_\infty - T_s)L_c^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.003472 \text{ K}^{-1})(25-5 \text{ K})(1.2 \text{ m})^3}{(1.471\times10^{-5} \text{ m}^2\text{/s})^2}(0.7323) = 3.986\times10^9$$

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(3.986\times10^9)^{1/6}}{\left[1+\left(\frac{0.492}{0.7323}\right)^{9/16}\right]^{8/27}}\right\}^2 = 189.7$$

$$h = \frac{k}{L}Nu = \frac{0.02476 \text{ W/m.°C}}{1.2 \text{ m}}(189.7) = \mathbf{3.915\ W/m^2.°C}$$
$$A_s = (1.2 \text{ m})(2 \text{ m}) = 2.4 \text{ m}^2$$

(*b*) The sum of the natural convection and radiation heat transfer from the room to the window is

$$\dot{Q}_{\text{convection}} = hA_s(T_\infty - T_s) = (3.915 \text{ W/m}^2.°\text{C})(2.4 \text{ m}^2)(25-5)°\text{C} = 187.9 \text{ W}$$
$$\dot{Q}_{\text{radiation}} = \varepsilon A_s\sigma(T_{surr}{}^4 - T_s{}^4)$$
$$= (0.9)(2.4 \text{ m}^2)(5.67\times10^{-8} \text{ W/m}^2.\text{K}^4)[(25+273 \text{ K})^4 - (5+273 \text{ K})^4] = 234.3 \text{ W}$$
$$\dot{Q}_{\text{total}} = \dot{Q}_{\text{convection}} + \dot{Q}_{\text{radiation}} = 187.9 + 234.3 = \mathbf{422.2\ W}$$

(*c*) The outer surface temperature of the window can be determined from

$$\dot{Q}_{\text{total}} = \frac{kA_s}{t}(T_{s,i} - T_{s,o}) \longrightarrow T_{s,o} = T_{s,i} - \frac{\dot{Q}_{\text{total}}t}{kA_s} = 5°\text{C} - \frac{(346 \text{ W})(0.006 \text{ m})}{(0.78 \text{ W/m.°C})(2.4 \text{ m}^2)} = 3.65°\text{C}$$

Then the combined natural convection and radiation heat transfer coefficient on the outer window surface becomes

$$\dot{Q}_{\text{total}} = h_{\text{combined}}A_s(T_{s,o} - T_{\infty,o})$$

or $$h_{\text{combined}} = \frac{\dot{Q}_{\text{total}}}{A_s(T_{s,o} - T_{\infty,o})} = \frac{346 \text{ W}}{(2.4 \text{ m}^2)[3.65-(-5)]°\text{C}} = \mathbf{20.35\ W/m^2.°C}$$

Note that $\Delta T = \dot{Q}R$ and thus the thermal resistance R of a layer is proportional to the temperature drop across that layer. Therefore, the fraction of thermal resistance of the glass is equal to the ratio of the temperature drop across the glass to the overall temperature difference,

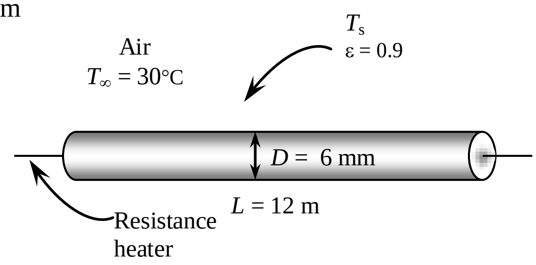
$$\frac{R_{\text{glass}}}{R_{\text{total}}} = \frac{\Delta T_{\text{glass}}}{\Delta TR_{\text{total}}} = \frac{5-3.65}{25-(-5)} = 0.045 \quad (\text{or } 4.5\%)$$

which is low. Thus it is reasonable to neglect the thermal resistance of the glass.

9-35 An insulated electric wire is exposed to calm air. The temperature at the interface of the wire and the plastic insulation is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2 = (50+30)/2 = 40°\text{C}$ are (Table A-15)



$$k = 0.02662\ \text{W/m.°C}$$
$$\upsilon = 1.702\times10^{-5}\ \text{m}^2/\text{s}$$
$$\text{Pr} = 0.7255$$
$$\beta = \frac{1}{T_f} = \frac{1}{(40+273)\text{K}} = 0.003195\ \text{K}^{-1}$$

Analysis The solution of this problem requires a trial-and-error approach since the determination of the Rayleigh number and thus the Nusselt number depends on the surface temperature which is unknown. We start the solution process by "guessing" the surface temperature to be 50°C for the evaluation of the properties and h. We will check the accuracy of this guess later and repeat the calculations if necessary. The characteristic length in this case is the outer diameter of the insulated wire $L_c = D = 0.006$ m. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)D^3}{\upsilon^2}\text{Pr} = \frac{(9.81\,\text{m/s}^2)(0.003195\,\text{K}^{-1})(50-30\,\text{K})(0.006\,\text{m})^3}{(1.702\times10^{-5}\ \text{m}^2/\text{s})^2}(0.7255) = 339.3$$

$$Nu = \left\{0.6 + \frac{0.387Ra^{1/6}}{\left[1+\left(0.559/\text{Pr}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6 + \frac{0.387(339.3)^{1/6}}{\left[1+\left(0.559/0.7255\right)^{9/16}\right]^{8/27}}\right\}^2 = 2.101$$

$$h = \frac{k}{D}Nu = \frac{0.02662\ \text{W/m.°C}}{0.006\ \text{m}}(2.101) = 9.327\ \text{W/m}^2.°\text{C}$$

$$A_s = \pi DL = \pi(0.006\ \text{m})(12\ \text{m}) = 0.2262\ \text{m}^2$$

The rate of heat generation, and thus the rate of heat transfer is

$$\dot{Q} = VI = (8\ \text{V})(10\ \text{A}) = 80\ \text{W}$$

Considering both natural convection and radiation, the total rate of heat loss can be expressed as

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$

$$80\ \text{W} = (9.327\ \text{W/m}^2.°\text{C})(0.226\ \text{m}^2)(T_s - 30)°\text{C}$$
$$+(0.9)(0.2262\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)[(T_s+273)^4 - (30+273\,\text{K})^4]$$

Its solution is

$$T_s = 52.6°\text{C}$$

which is close to the assumed value of 50°C. Then the temperature at the interface of the wire and the plastic cover in steady operation becomes

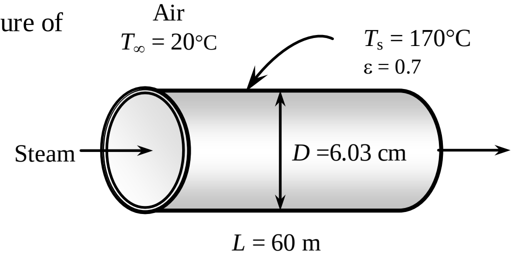
$$\dot{Q} = \frac{2\pi kL}{\ln(D_2/D_1)}(T_i - T_s) \longrightarrow T_i = T_s + \frac{\dot{Q}\ln(D_2/D_1)}{2\pi kL} = 52.6°\text{C} + \frac{(80\ \text{W})\ln(6/3)}{2\pi(0.15\ \text{W/m.°C})(12\ \text{m})} = \mathbf{57.5°C}$$

9-36 A steam pipe extended from one end of a plant to the other with no insulation on it. The rate of heat loss from the steam pipe and the annual cost of those heat losses are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (170+20)/2 = 95°\text{C}$ are (Table A-15)

$$k = 0.0306 \text{ W/m.°C}$$
$$\upsilon = 2.252\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7121$$
$$\beta = \frac{1}{T_f} = \frac{1}{(95+273)\text{K}} = 0.002717 \text{ K}^{-1}$$



Analysis The characteristic length in this case is the outer diameter of the pipe, $L_c = D = 0.0603 \text{ m}$. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)D^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.002717 \text{ K}^{-1})(170-20 \text{ K})(0.0603 \text{ m})^3}{(2.252\times10^{-5} \text{ m}^2\text{/s})^2}(0.7121) = 1.231\times10^6$$

$$Nu = \left\{0.6 + \frac{0.387 Ra^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6 + \frac{0.387(1.231\times10^6)^{1/6}}{\left[1+(0.559/0.7121)^{9/16}\right]^{8/27}}\right\}^2 = 15.42$$

$$h = \frac{k}{D}Nu = \frac{0.0306 \text{ W/m.°C}}{0.0603 \text{ m}}(15.42) = 7.823 \text{ W/m}^2\text{.°C}$$
$$A_s = \pi DL = \pi(0.0603 \text{ m})(60 \text{ m}) = 11.37 \text{ m}^2$$

Then the total rate of heat transfer by natural convection and radiation becomes

$$\begin{aligned}\dot{Q} &= hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s^{\,4} - T_{surr}^{\,4}) \\ &= (7.823 \text{ W/m}^2\text{.°C})(11.37 \text{ m}^2)(170-20)°\text{C} \\ &\quad + (0.7)(11.37 \text{ m}^2)(5.67\times10^{-8} \text{ W/m}^2\text{.K}^4)[(170+273 \text{ K})^4 - (20+273 \text{ K})^4] \\ &= 27{,}388\, W = \mathbf{27.4\ kW}\end{aligned}$$

The total amount of gas consumption and its cost during a one-year period is

$$Q_{gas} = \frac{\dot{Q}\Delta t}{\eta} = \frac{27.388 \text{ kJ/s}}{0.78}\left(\frac{1 \text{ therm}}{105{,}500 \text{ kJ}}\right)(8760 \text{ h/yr}\times3600 \text{ s/h}) = 10{,}496 \text{ therms/yr}$$

$$\text{Cost} = (10{,}496 \text{ therms/yr})(\$0.538/\text{therm}) = \mathbf{\$5647/yr}$$

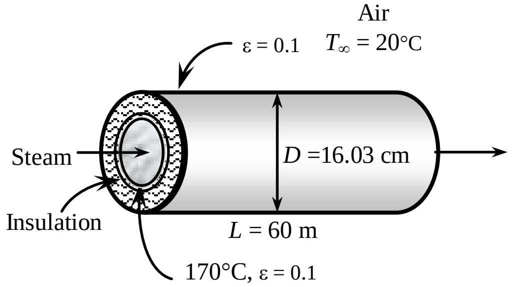
9-38 A steam pipe extended from one end of a plant to the other. It is proposed to insulate the steam pipe for $750. The simple payback period of the insulation to pay for itself from the energy it saves are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2$ = (35+20)/2 = 27.5°C are (Table A-15)

$$k = 0.0257 \text{ W/m.°C}$$
$$\upsilon = 1.584\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7289$$
$$\beta = \frac{1}{T_f} = \frac{1}{(27.5+273)\text{K}} = 0.003328 \text{ K}^{-1}$$



Analysis Insulation will drop the outer surface temperature to a value close to the ambient temperature. The solution of this problem requires a trial-and-error approach since the determination of the Rayleigh number and thus the Nusselt number depends on the surface temperature which is unknown. We start the solution process by "guessing" the outer surface temperature to be 35°C for the evaluation of the properties and *h*. We will check the accuracy of this guess later and repeat the calculations if necessary. The characteristic length in this case is the outer diameter of the insulated pipe, $L_c = D = 0.1603\text{ m}$. Then,

$$Ra = \frac{g\beta(T_s-T_\infty)D^3}{\upsilon^2}\text{Pr} = \frac{(9.81\text{ m/s}^2)(0.003328\text{ K}^{-1})(35-20\text{ K})(0.1603\text{ m})^3}{(1.584\times10^{-5}\text{ m}^2\text{/s})^2}(0.7289) = 5.856\times10^6$$

$$Nu = \left\{0.6+\frac{0.387Ra^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6+\frac{0.387(5.856\times10^6)^{1/6}}{\left[1+(0.559/0.7289)^{9/16}\right]^{8/27}}\right\}^2 = 24.23$$

$$h = \frac{k}{D}Nu = \frac{0.0257\text{ W/m.°C}}{0.1603\text{ m}}(24.23) = 3.884\text{ W/m}^2\text{.°C}$$

$$A_s = \pi DL = \pi(0.1603\text{ m})(60\text{ m}) = 30.22\text{ m}^2$$

Then the total rate of heat loss from the outer surface of the insulated pipe by convection and radiation becomes

$$\begin{aligned}\dot{Q} &= \dot{Q}_{conv}+\dot{Q}_{rad} = hA_s(T_s-T_\infty)+\varepsilon A_s\sigma(T_s{}^4-T_{surr}{}^4)\\ &= (3.884\text{ W/m}^2\text{.°C})(30.22\text{ m}^2)(35-20)\text{°C}\\ &\quad+(0.1)(30.22\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\text{.K}^4)[(35+273\text{ K})^4-(20+273\text{ K})^4]\\ &= 2039\text{ W}\end{aligned}$$

In steady operation, the heat lost from the exposed surface of the insulation by convection and radiation must be equal to the heat conducted through the insulation. This requirement gives the surface temperature to be

$$\dot{Q} = \dot{Q}_{\text{insulation}} = \frac{T_{s.i}-T_s}{R_{ins}} = \frac{T_{s.i}-T_s}{\dfrac{\ln(D_2/D_1)}{2\pi kL}} \rightarrow 2039\text{ W} = \frac{(170-T_s)\text{°C}}{\dfrac{\ln(16.03/6.03)}{2\pi(0.038\text{ W/m.°C})(60\text{ m})}}$$

It gives 30.8°C for the surface temperature, which is somewhat different than the assumed value of 35°C. Repeating the calculations with other surface temperatures gives

$$T_s = 34.3\text{°C} \quad \text{and } \dot{Q} = 1988\text{ W}$$

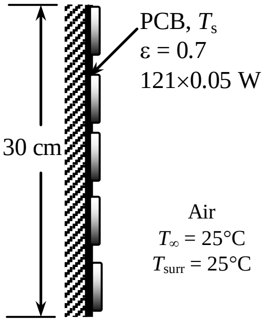
Heat loss and its cost without insulation was determined in the Prob. 9-36 to be 27.388 kW and $5647. Then the reduction in the heat losses becomes

$$\dot{Q}_{\text{saved}} = 27.388-1.988 \cong 25.40\text{ kW} \quad \text{or} \quad 25.388/27.40 = 0.927 \quad (92.7\%)$$

Therefore, the money saved by insulation will be 0.921×($5647/yr) = **$5237/yr** which will pay for the cost of $750 in $750/($5237/yr)=0.1432 year = **52.3 days**.

9-39 A circuit board containing square chips is mounted on a vertical wall in a room. The surface temperature of the chips is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** The heat transfer from the back side of the circuit board is negligible.



Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2 = (35+25)/2 = 30°C$ are (Table A-15)

$$k = 0.02588\ \text{W/m.°C}$$
$$\upsilon = 1.608\times10^{-5}\ \text{m}^2/\text{s}$$
$$\text{Pr} = 0.7282$$
$$\beta = \frac{1}{T_f} = \frac{1}{(30+273)\text{K}} = 0.0033\ \text{K}^{-1}$$

Analysis The solution of this problem requires a trial-and-error approach since the determination of the Rayleigh number and thus the Nusselt number depends on the surface temperature which is unknown. We start the solution process by "guessing" the surface temperature to be 35°C for the evaluation of the properties and *h*. We will check the accuracy of this guess later and repeat the calculations if necessary. The characteristic length in this case is the height of the board, $L_c = L = 0.3\ \text{m}$. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81\ \text{m/s}^2)(0.0033\ \text{K}^{-1})(35-25\ \text{K})(0.3\ \text{m})^3}{(1.608\times10^{-5}\ \text{m}^2/\text{s})^2}(0.7282) = 2.463\times10^7$$

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(2.463\times10^7)^{1/6}}{\left[1+\left(\frac{0.492}{0.7282}\right)^{9/16}\right]^{8/27}}\right\}^2 = 40.57$$

$$h = \frac{k}{L}Nu = \frac{0.02588\ \text{W/m.°C}}{0.3\ \text{m}}(40.57) = 3.50\ \text{W/m}^2.\text{°C}$$
$$A_s = (0.3\ \text{m})^2 = 0.09\ \text{m}^2$$

Considering both natural convection and radiation, the total rate of heat loss can be expressed as

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$
$$(121\times0.05)\ \text{W} = (3.50\ \text{W/m}^2.\text{°C})(0.09\ \text{m}^2)(T_s - 25)\text{°C}$$
$$+(0.7)(0.09\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)[(T_s + 273\ \text{K})^4 - (25+273\ \text{K})^4]$$

Its solution is

T_s = **33.5°C**

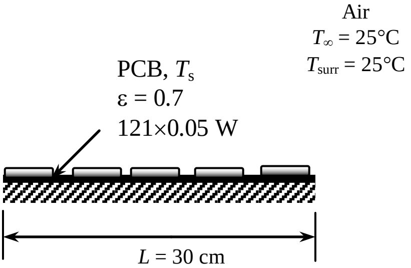
which is sufficiently close to the assumed value in the evaluation of properties and *h*. Therefore, there is no need to repeat calculations by reevaluating the properties and *h* at the new film temperature.

9-40 A circuit board containing square chips is positioned horizontally in a room. The surface temperature of the chips is to be determined for two orientations.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** The heat transfer from the back side of the circuit board is negligible.

Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2 = (35+25)/2 = 30°\text{C}$ are (Table A-15)

$$k = 0.02588\ \text{W/m.°C}$$
$$\upsilon = 1.608\times10^{-5}\ \text{m}^2\text{/s}$$
$$\text{Pr} = 0.7282$$
$$\beta = \frac{1}{T_f} = \frac{1}{(30+273)\text{K}} = 0.0033\ \text{K}^{-1}$$



Analysis The solution of this problem requires a trial-and-error approach since the determination of the Rayleigh number and thus the Nusselt number depends on the surface temperature which is unknown. We start the solution process by "guessing" the surface temperature to be 35°C for the evaluation of the properties and *h*. The characteristic length for both cases is determined from

$$L_c = \frac{A_s}{p} = \frac{(0.3\,\text{m})^2}{2[(0.3\,\text{m})+(0.3\,\text{m})]} = 0.075\ \text{m}.$$

Then,

$$Ra = \frac{g\beta(T_s-T_\infty)L_c^3}{\upsilon^2}\text{Pr} = \frac{(9.81\,\text{m/s}^2)(0.00333\,\text{K}^{-1})(35-25\,\text{K})(0.075\,\text{m})^3}{(1.608\times10^{-5}\ \text{m}^2\text{/s})^2}(0.7282) = 3.848\times10^5$$

(*a*) Chips (hot surface) facing up:

$$Nu = 0.54Ra^{1/4} = 0.54(3.848\times10^5)^{1/4} = 13.45$$
$$h = \frac{k}{L_c}Nu = \frac{0.02588\ \text{W/m.°C}}{0.075\ \text{m}}(13.45) = 4.641\ \text{W/m}^2\text{.°C}$$
$$A_s = (0.3\,\text{m})^2 = 0.09\ \text{m}^2$$

Considering both natural convection and radiation, the total rate of heat loss can be expressed as

$$\dot{Q} = hA_s(T_s-T_\infty) + \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$
$$(121\times0.05)\ \text{W} = (4.641\ \text{W/m}^2\text{.°C})(0.09\ \text{m}^2)(T_s-25)\text{°C}$$
$$+(0.7)(0.09\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\text{.K}^4)[(T_s+273\,\text{K})^4-(25+273\,\text{K})^4]$$

Its solution is T_s = **32.5°C**

which is sufficiently close to the assumed value. Therefore, there is no need to repeat calculations.

(*b*) Chips (hot surface) facing up:

$$Nu = 0.27Ra^{1/4} = 0.27(3.848\times10^5)^{1/4} = 6.725$$
$$h = \frac{k}{L_c}Nu = \frac{0.02588\ \text{W/m.°C}}{0.075\ \text{m}}(6.725) = 2.321\ \text{W/m}^2\text{.°C}$$

Considering both natural convection and radiation, the total rate of heat loss can be expressed as

$$\dot{Q} = hA_s(T_s-T_\infty) + \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$
$$(121\times0.05)\ \text{W} = (2.321\ \text{W/m}^2\text{.°C})(0.09\ \text{m}^2)(T_s-25)\text{°C}$$
$$+(0.7)(0.09\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\text{.K}^4)[(T_s+273\,\text{K})^4-(25+273\,\text{K})^4]$$

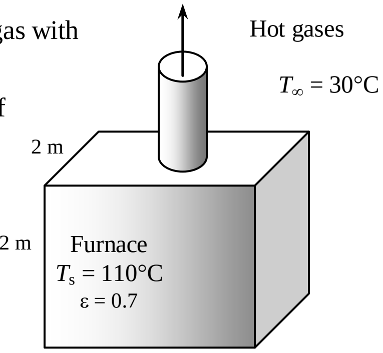
Its solution is T_s = **35.0°C**

which is identical to the assumed value in the evaluation of properties and *h*. Therefore, there is no need to repeat calculations.

9-41 It is proposed that the side surfaces of a cubic industrial furnace be insulated for \$550 in order to reduce the heat loss by 90 percent. The thickness of the insulation and the payback period of the insulation to pay for itself from the energy it saves are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (110+30)/2 = 70°\text{C}$ are (Table A-15)



$$k = 0.02881\ \text{W/m.°C}$$
$$\upsilon = 1.995\times10^{-5}\ \text{m}^2/\text{s}$$
$$\text{Pr} = 0.7177$$
$$\beta = \frac{1}{T_f} = \frac{1}{(70+273)\text{K}} = 0.002915\ \text{K}^{-1}$$

Analysis The characteristic length in this case is the height of the furnace, $L_c = L = 2$ m. Then,

$$Ra = \frac{g\beta(T_s-T_\infty)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81\ \text{m/s}^2)(0.002915\ \text{K}^{-1})(110-30\ \text{K})(2\ \text{m})^3}{(1.995\times10^{-5}\ \text{m}^2/\text{s})^2}(0.7177) = 3.301\times10^{10}$$

$$Nu = \left\{0.825+\frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825+\frac{0.387(3.301\times10^{10})^{1/6}}{\left[1+\left(\frac{0.492}{0.7177}\right)^{9/16}\right]^{8/27}}\right\}^2 = 369.2$$

$$h = \frac{k}{L_c}Nu = \frac{0.02881\ \text{W/m.°C}}{2\ \text{m}}(369.2) = 5.318\ \text{W/m}^2.\text{°C}$$
$$A_s = 4(2\ \text{m})^2 = 16\ \text{m}^2$$

Then the heat loss by combined natural convection and radiation becomes

$$\begin{aligned}\dot{Q} &= hA_s(T_s-T_\infty)+\varepsilon A_s\sigma(T_s{}^4-T_{surr}{}^4)\\ &= (5.318\ \text{W/m}^2.\text{°C})(16\ \text{m}^2)(110-30)\text{°C}\\ &\quad +(0.7)(16\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)[(110+273\ \text{K})^4-(30+273\ \text{K})^4]\\ &= 15{,}119\ \text{W}\end{aligned}$$

Noting that insulation will reduce the heat losses by 90%, the rate of heat loss after insulation will be

$$\dot{Q}_\text{saved} = 0.9\dot{Q}_\text{no insulation} = 0.9\times15{,}119\ \text{W} = 13{,}607\ \text{W}$$
$$\dot{Q}_\text{loss} = (1-0.9)\dot{Q}_\text{no insulation} = 0.1\times15{,}119\ \text{W} = 1512\ \text{W}$$

The furnace operates continuously and thus 8760 h. Then the amount of energy and money the insulation will save becomes

$$\text{Energy saved} = \dot{Q}_{saved}\Delta t = \frac{13.607\ \text{kJ/s}}{0.78}\left(\frac{1\ \text{therm}}{105{,}500\ \text{kJ}}\right)(8760\times3600\ \text{s/yr}) = 5215\ \text{therms/yr}$$

$$\text{Money saved} = \text{(Energy saved)(Unit cost of energy)} = \text{(5215 therms)(\$0.55 / therm)} = \$2868$$

Therefore, the money saved by insulation will pay for the cost of \$550 in
550/(\$2868/yr)=0.1918 yr = **70 days**.

Insulation will lower the outer surface temperature, the Rayleigh and Nusselt numbers, and thus the convection heat transfer coefficient. For the evaluation of the heat transfer coefficient, we assume the surface temperature in this case to be 50°C. The properties of air at the film temperature of $(T_s+T_\infty)/2$ = (50+30)/2 = 40°C are (Table A-15)

$$k = 0.02662\ \text{W/m.°C}$$

$$\upsilon = 1.702\times10^{-5}\ \text{m}^2\text{/s}$$

$$\text{Pr} = 0.7255$$

$$\beta = \frac{1}{T_f} = \frac{1}{(40+273)\text{K}} = 0.003195\ \text{K}^{-1}$$

Then,

$$Ra = \frac{g\beta(T_s - T_\infty)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81\,\text{m/s}^2)(0.003195\,\text{K}^{-1})(50-30\,\text{K})(2\,\text{m})^3}{(1.702\times10^{-5}\ \text{m}^2\text{/s})^2}(0.7255) = 1.256\times10^{10}$$

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(1.256\times10^{10})^{1/6}}{\left[1+\left(\frac{0.492}{0.7255}\right)^{9/16}\right]^{8/27}}\right\}^2 = 272.0$$

$$h = \frac{k}{L}Nu = \frac{0.02662\ \text{W/m.°C}}{2\ \text{m}}(272.0) = 3.620\ \text{W/m}^2\text{.°C}$$

$$A_s = 4\times(2\ \text{m})(2+2t_{insul})\ \text{m}$$

The total rate of heat loss from the outer surface of the insulated furnace by convection and radiation becomes

$$\dot{Q} = \dot{Q}_{conv} + \dot{Q}_{rad} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$

$$1512\ \text{W} = (3.620\ \text{W/m}^2\text{.°C})A(T_s - 30)\text{°C} + (0.7)A(5.67\times10^{-8}\ \text{W/m}^2\text{.K}^4)[(T_s + 273\,\text{K})^4 - (30+273\,\text{K})^4]$$

In steady operation, the heat lost by the side surfaces of the pipe must be equal to the heat lost from the exposed surface of the insulation by convection and radiation, which must be equal to the heat conducted through the insulation. Therefore,

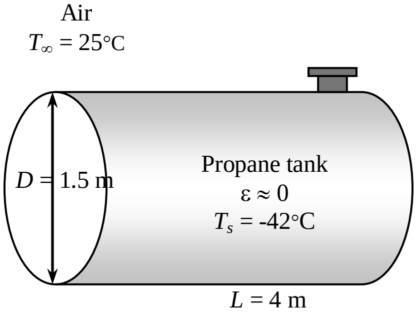
$$\dot{Q} = \dot{Q}_{insulation} = kA_s\frac{(T_{\text{furnace}} - T_s)}{t_{ins}} \rightarrow 1512\ \text{W} = (0.038\ \text{W/m.°C})A_s\frac{(110 - T_s)\text{°C}}{t_{insul}}$$

Solving the two equations above by trial-and error (or better yet, an equation solver) gives

T_s = 48.4°C and t_{insul} = 0.0254 m = **2.54 cm**

9-42 A cylindrical propane tank is exposed to calm ambient air. The propane is slowly vaporized due to a crack developed at the top of the tank. The time it will take for the tank to empty is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** Radiation heat transfer is negligible.



Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2$ = (-42+25)/2 = -8.5°C are (Table A-15)

$$k = 0.02299 \text{ W/m.°C}$$
$$\upsilon = 1.265\times10^{-5} \text{ m}^2\text{/s}$$
$$\Pr = 0.7383$$
$$\beta = \frac{1}{T_f} = \frac{1}{(-8.5+273)\text{K}} = 0.003781 \text{ K}^{-1}$$

Analysis The tank gains heat through its cylindrical surface as well as its circular end surfaces. For convenience, we take the heat transfer coefficient at the end surfaces of the tank to be the same as that of its side surface. (The alternative is to treat the end surfaces as a vertical plate, but this will double the amount of calculations without providing much improvement in accuracy since the area of the end surfaces is much smaller and it is circular in shape rather than being rectangular). The characteristic length in this case is the outer diameter of the tank, $L_c = D = 1.5$ m. Then,

$$Ra = \frac{g\beta(T_\infty - T_s)D^3}{\upsilon^2}\Pr = \frac{(9.81 \text{ m/s}^2)(0.003781 \text{ K}^{-1})[(25-(-42) \text{ K}](1.5 \text{ m})^3}{(1.265\times10^{-5} \text{ m}^2\text{/s})^2}(0.7383) = 3.869\times10^{10}$$

$$Nu = \left\{0.6 + \frac{0.387 Ra^{1/6}}{\left[1+(0.559/\Pr)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6 + \frac{0.387(3.869\times10^{10})^{1/6}}{\left[1+(0.559/0.7383)^{9/16}\right]^{8/27}}\right\}^2 = 374.1$$

$$h = \frac{k}{D}Nu = \frac{0.02299 \text{ W/m.°C}}{1.5 \text{ m}}(374.1) = 5.733 \text{ W/m}^2\text{.°C}$$

$$A_s = \pi DL + 2\pi D^2/4 = \pi(1.5 \text{ m})(4 \text{ m}) + 2\pi(1.5 \text{ m})^2/4 = 22.38 \text{ m}^2$$

and

$$\dot{Q} = hA_s(T_\infty - T_s) = (5.733 \text{ W/m}^2\text{.°C})(22.38 \text{ m}^2)[(25-(-42)]\text{°C} = 8598 \text{ W}$$

The total mass and the rate of evaporation of propane are

$$m = \rho V = \rho\frac{\pi D^2}{4}L = (581 \text{ kg/m}^3)\frac{\pi(1.5 \text{ m})^2}{4}(4 \text{ m}) = 4107 \text{ kg}$$

$$\dot{m} = \frac{\dot{Q}}{h_{fg}} = \frac{8.598 \text{ kJ/s}}{425 \text{ kJ/kg}} = 0.02023 \text{ kg/s}$$

and it will take

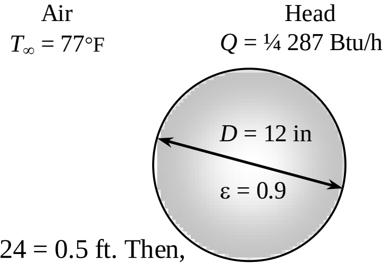
$$\Delta t = \frac{m}{\dot{m}} = \frac{4107 \text{ kg}}{0.02023 \text{ kg/s}} = 202{,}996 \text{ s} = \mathbf{56.4 \text{ hours}}$$

for the propane tank to empty.

9-43E The average surface temperature of a human head is to be determined when it is not covered.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** The head can be approximated as a 12-in.-diameter sphere.

Properties The solution of this problem requires a trial-and-error approach since the determination of the Rayleigh number and thus the Nusselt number depends on the surface temperature which is unknown. We start the solution process by "guessing" the surface temperature to be 120°F for the evaluation of the properties and *h*. We will check the accuracy of this guess later and repeat the calculations if necessary. The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2 = (120+77)/2 = 98.5$°F are (Table A-15E)



$$k = 0.01525 \text{ Btu/h.ft.°F}$$

$$\upsilon = 0.180\times10^{-3} \text{ ft}^2\text{/s}$$

$$\text{Pr} = 0.7262$$

$$\beta = \frac{1}{T_f} = \frac{1}{(98.5+460)\text{R}} = 0.001791 \text{ R}^{-1}$$

Analysis The characteristic length for a spherical object is $L_c = D = 12/24 = 0.5$ ft. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)D^3}{\upsilon^2}\text{Pr} = \frac{(32.2 \text{ ft/s}^2)(0.001791 \text{ R}^{-1})(95-77 \text{ R})(0.5 \text{ ft})^3}{(0.180\times10^{-3} \text{ ft}^2\text{/s})^2}(0.7262) = 6.943\times10^6$$

$$Nu = 2 + \frac{0.589Ra^{1/4}}{\left[1+\left(\frac{0.469}{\text{Pr}}\right)^{9/16}\right]^{4/9}} = 2 + \frac{0.589(6.943\times10^6)^{1/4}}{\left[1+\left(\frac{0.469}{0.7262}\right)^{9/16}\right]^{4/9}} = 25.39$$

$$h = \frac{k}{D}Nu = \frac{0.01525 \text{ Btu/h.ft.°F}}{1 \text{ ft}}(25.39) = 0.7744 \text{ Btu/h.ft}^2\text{.°F}$$

$$A_s = \pi D^2 = \pi(0.5 \text{ ft})^2 = 0.7854 \text{ ft}^2$$

Considering both natural convection and radiation, the total rate of heat loss can be written as

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$

$$(287/4 \text{ Btu/h}) = (0.7744 \text{ Btu/h.ft}^2\text{.°F})(0.7854 \text{ ft}^2)(T_s - 77)\text{°F}$$
$$+ (0.9)(0.7854 \text{ m}^2)(0.1714\times10^{-8} \text{ Btu/h.ft}^2\text{.R}^4)[(T_s + 460 \text{ R})^4 - (77+460 \text{ R})^4]$$

Its solution is

T_s = **125.9°F**

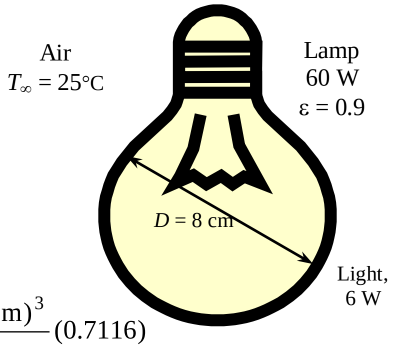
which is sufficiently close to the assumed value in the evaluation of the properties and *h*. Therefore, there is no need to repeat calculations.

9-44 The equilibrium temperature of a light glass bulb in a room is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** The light bulb is approximated as an 8-cm-diameter sphere.

Properties The solution of this problem requires a trial-and-error approach since the determination of the Rayleigh number and thus the Nusselt number depends on the surface temperature which is unknown. We start the solution process by "guessing" the surface temperature to be 170°C for the evaluation of the properties and *h*. We will check the accuracy of this guess later and repeat the calculations if necessary. The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2 = (170+25)/2 = 97.5$°C are (Table A-15)

$$k = 0.03077 \text{ W/m.°C}$$
$$\upsilon = 2.279\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7116$$
$$\beta = \frac{1}{T_f} = \frac{1}{(97.5+273)\text{K}} = 0.002699 \text{ K}^{-1}$$



Analysis The characteristic length in this case is $L_c = D = 0.08$ m. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)D^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.002699 \text{ K}^{-1})(170-25 \text{ K})(0.08 \text{ m})^3}{(2.279\times10^{-5} \text{ m}^2\text{/s})^2}(0.7116)$$
$$= 2.694\times10^6$$

$$Nu = 2 + \frac{0.589Ra^{1/4}}{\left[1+\left(0.469/\text{Pr}\right)^{9/16}\right]^{4/9}} = 2 + \frac{0.589(2.694\times10^6)^{1/4}}{\left[1+\left(0.469/0.7116\right)^{9/16}\right]^{4/9}} = 20.42$$

Then

$$h = \frac{k}{D}Nu = \frac{0.03077 \text{ W/m.°C}}{0.08 \text{ m}}(20.42) = 7.854 \text{ W/m}^2\text{.°C}$$
$$A_s = \pi D^2 = \pi(0.08 \text{ m})^2 = 0.02011 \text{ m}^2$$

Considering both natural convection and radiation, the total rate of heat loss can be written as

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$
$$(0.90\times60)\text{ W} = (7.854 \text{ W/m}^2\text{.°C})(0.02011 \text{ m}^2)(T_s - 25)\text{°C}$$
$$+(0.9)(0.02011 \text{ m}^2)(5.67\times10^{-8} \text{ W/m}^2\text{.K}^4)[(T_s+273)^4 - (25+273 \text{ K})^4]$$

Its solution is

T_s = **169.4°C**

which is sufficiently close to the value assumed in the evaluation of properties and *h*. Therefore, there is no need to repeat calculations.

9-45 A vertically oriented cylindrical hot water tank is located in a bathroom. The rate of heat loss from the tank by natural convection and radiation is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** The temperature of the outer surface of the tank is constant.

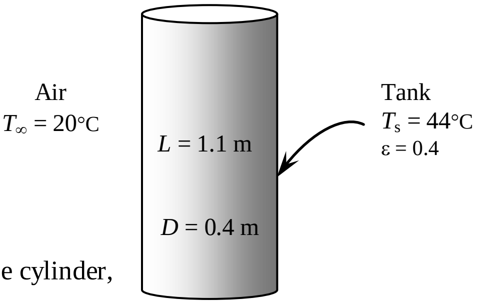
Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (44+20)/2 = 32$°C are (Table A-15)

$$k = 0.02603 \text{ W/m.°C}$$

$$\upsilon = 1.627\times10^{-5} \text{ m}^2\text{/s}$$

$$\text{Pr} = 0.7276$$

$$\beta = \frac{1}{T_f} = \frac{1}{(32+273)\text{K}} = 0.003279 \text{ K}^{-1}$$



Analysis The characteristic length in this case is the height of the cylinder, $L_c = L = 1.1\text{ m}$. Then,

$$\text{Gr} = \frac{g\beta(T_s-T_\infty)L^3}{\upsilon^2} = \frac{(9.81 \text{ m/s}^2)(0.003279 \text{ K}^{-1})(44-20 \text{ K})(1.1 \text{ m})^3}{(1.627\times10^{-5} \text{ m}^2\text{/s})^2} = 3.883\times10^9$$

A vertical cylinder can be treated as a vertical plate when

$$D(= 0.4 \text{ m}) \ge \frac{35L}{\text{Gr}^{1/4}} = \frac{35(1.1 \text{ m})}{(3.883\times10^9)^{1/4}} = 0.1542 \text{ m}$$

which is satisfied. That is, the Nusselt number relation for a vertical plate can be used for the side surfaces. For the top and bottom surfaces we use the relevant Nusselt number relations. First, for the side surfaces,

$$\text{Ra} = \text{GrPr} = (3.883\times10^9)(0.7276) = 2.825\times10^9$$

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(2.825\times10^9)^{1/6}}{\left[1+\left(\frac{0.492}{0.7276}\right)^{9/16}\right]^{8/27}}\right\}^2 = 170.2$$

$$h = \frac{k}{L}Nu = \frac{0.02603 \text{ W/m.°C}}{1.1 \text{ m}}(170.2) = 4.027 \text{ W/m}^2\text{.°C}$$

$$A_s = \pi DL = \pi(0.4 \text{ m})(1.1 \text{ m}) = 1.382 \text{ m}^2$$

$$\dot{Q}_{\text{side}} = hA_s(T_s-T_\infty) = (4.027 \text{ W/m}^2\text{.°C})(1.382 \text{ m}^2)(44-20)\text{°C} = 133.6 \text{ W}$$

For the top surface,

$$L_c = \frac{A_s}{p} = \frac{\pi D^2/4}{\pi D} = \frac{D}{4} = \frac{0.4 \text{ m}}{4} = 0.1 \text{ m}$$

$$\text{Ra} = \frac{g\beta(T_s-T_\infty)L_c^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.003279 \text{ K}^{-1})(44-20 \text{ K})(0.1 \text{ m})^3}{(1.627\times10^{-5} \text{ m}^2\text{/s})^2}(0.7276) = 2.123\times10^6$$

$$\text{Nu} = 0.54\text{Ra}^{1/4} = 0.54(2.123\times10^6)^{1/4} = 20.61$$

$$h = \frac{k}{L_c}Nu = \frac{0.02603 \text{ W/m.°C}}{0.1 \text{ m}}(20.61) = 5.365 \text{ W/m}^2\text{.°C}$$

$$A_s = \pi D^2/4 = \pi(0.4 \text{ m})^2/4 = 0.1257 \text{ m}^2$$

$$\dot{Q}_{\text{top}} = hA_s(T_s-T_\infty) = (5.365 \text{ W/m}^2\text{.°C})(0.1257 \text{ m}^2)(44-20)\text{°C} = 16.2 \text{ W}$$

For the bottom surface,

$$\text{Nu} = 0.27\text{Ra}^{1/4} = 0.27(2.123\times10^6)^{1/4} = 10.31$$

$$h = \frac{k}{L_c} Nu = \frac{0.02603\ \text{W/m.°C}}{0.1\ \text{m}}(10.31) = 2.683\ \text{W/m}^2.\text{°C}$$

$$\dot{Q}_{\text{bottom}} = hA_s(T_s - T_\infty) = (2.683\ \text{W/m}^2.\text{°C})(0.1257\ \text{m}^2)(44-20)\text{°C} = 8.1\ \text{W}$$

The total heat loss by natural convection is

$$\dot{Q}_{\text{conv}} = \dot{Q}_{\text{side}} + \dot{Q}_{\text{top}} + \dot{Q}_{\text{bottom}} = 133.6 + 16.2 + 8.1 = \mathbf{157.9\ W}$$

The radiation heat loss from the tank is

$$\begin{aligned}\dot{Q}_{\text{rad}} &= \varepsilon A_s \sigma (T_s{}^4 - T_{surr}{}^4) \\ &= (0.4)(1.382 + 0.1257 + 0.1257\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)\left[(44+273\ \text{K})^4 - (20+273\ \text{K})^4\right] \\ &= \mathbf{101.1\ W}\end{aligned}$$

9-46 A rectangular container filled with cold water is gaining heat from its surroundings by natural convection and radiation. The water temperature in the container after a 3 hours and the average rate of heat transfer are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** The heat transfer coefficient at the top and bottom surfaces is the same as that on the side surfaces.

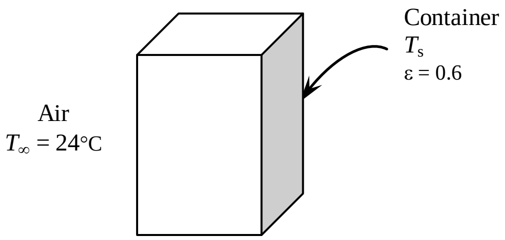
Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2 = (10+24)/2 = 17°\text{C}$ are (Table A-15)

$$k = 0.02491\ \text{W/m.°C}$$

$$\upsilon = 1.489\times10^{-5}\ \text{m}^2/\text{s}$$

$$\text{Pr} = 0.7317$$

$$\beta = \frac{1}{T_f} = \frac{1}{(17+273)\text{K}} = 0.003448\ \text{K}^{-1}$$



The properties of water at 2°C are (Table A-7)

$$\rho = 1000\ \text{kg/m}^3 \ \text{ and } \ C_p = 4214\ \text{J/kg.°C}$$

Analysis We first evaluate the heat transfer coefficient on the side surfaces. The characteristic length in this case is the height of the container,

$L_c = L = 0.28\ \text{m}$. Then,

$$\text{Ra} = \frac{g\beta(T_\infty - T_s)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81\ \text{m/s}^2)(0.003448\ \text{K}^{-1})(24-10\ \text{K})(0.28\ \text{m})^3}{(1.489\times10^{-5}\ \text{m}^2/\text{s})^2}(0.7317) = 1.133\times10^7$$

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(1.133\times10^7)^{1/6}}{\left[1+\left(\frac{0.492}{0.7317}\right)^{9/16}\right]^{8/27}}\right\}^2 = 30.52$$

$$h = \frac{k}{L}Nu = \frac{0.02491\ \text{W/m.°C}}{0.28\ \text{m}}(30.52) = 4.224\ \text{W/m}^2\text{.°C}$$

$$A_s = 2(0.28\times0.18 + 0.28\times0.18 + 0.18\times0.18) = 0.2664\ \text{m}^2$$

The rate of heat transfer can be expressed as

$$\dot{Q} = \dot{Q}_\text{conv} + \dot{Q}_\text{rad} = hA_s\left(T_\infty - \frac{T_1+T_2}{2}\right) + \varepsilon\sigma A_s\left[T_\text{surr}{}^4 - \left(\frac{T_1+T_2}{2}\right)^4\right]$$

$$= (4.224\ \text{W/m}^2\text{.°C})(0.2664\ \text{m}^2)\left[297 - \left(\frac{275+T_2}{2}\right)\right] \qquad \text{(Eq. 1)}$$

$$+ (0.6)(0.2664\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\text{.K}^4)\left[297^4 - \left(\frac{275+T_2}{2}\right)^4\right]$$

where $(T_1+T_2)/2$ is the average temperature of water (or the container surface). The mass of water in the container is

$$m = \rho V = (1000\ \text{kg/m}^3)(0.28\times0.18\times0.18)\text{m}^3 = 9.072\ \text{kg}$$

Then the amount of heat transfer to the water is

$$Q = mC_p(T_2 - T_1) = (9.072\ \text{kg})(4214\ \ \text{J/kg.°C})(T_2 - 275)\text{°C} = 38{,}229(T_2 - 275)$$

The average rate of heat transfer can be expressed as

$$\dot{Q} = \frac{Q}{\Delta t} = \frac{38{,}229(T_2 - 275)}{3\times3600\ \text{s}} = 3.53976(T_2 - 275) \qquad \text{(Eq. 2)}$$

Setting Eq. 1 and Eq. 2 equal to each other, we obtain the final water temperature.

$$T_2 = 284.7\ \text{K} = \mathbf{11.7°C}$$

We could repeat the solution using air properties at the new film temperature using this value to increase the accuracy. However, this would only affect the heat transfer value somewhat, which would not have significant effect on the final water temperature. The average rate of heat transfer can be determined from Eq. 2

$$\dot{Q} = 3.53976(11.7 - 2) = \mathbf{34.3\ W}$$

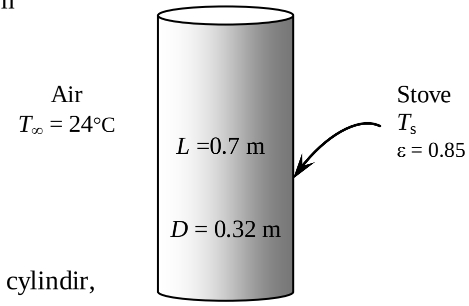
9-48 A room is to be heated by a cylindrical coal-burning stove. The surface temperature of the stove and the amount of coal burned during a 30-day-period are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** The temperature of the outer surface of the stove is constant. **5** The heat transfer from the bottom surface is negligible. **6** The heat transfer coefficient at the top surface is the same as that on the side surface.

Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2 = (130+24)/2 = 77°C$ are (Table A-1)

$$k = 0.02931\ \text{W/m.°C}$$
$$\upsilon = 2.066\times10^{-5}\ \text{m}^2/\text{s}$$
$$\Pr = 0.7161$$
$$\beta = \frac{1}{T_f} = \frac{1}{(77+273)\text{K}} = 0.002857\ \text{K}^{-1}$$



Analysis The characteristic length in this case is the height of the cylindir, $L_c = L = 0.7\ \text{m}$. Then,

$$\text{Gr} = \frac{g\beta(T_s-T_\infty)L^3}{\upsilon^2} = \frac{(9.81\ \text{m/s}^2)(0.002857\ \text{K}^{-1})(130-24\ \text{K})(0.70\ \text{m})^3}{(2.066\times10^{-5}\ \text{m}^2/\text{s})^2} = 2.387\times10^9$$

A vertical cylinder can be treated as a vertical plate when

$$D(=0.32\ \text{m}) \geq \frac{35L}{\text{Gr}^{1/4}} = \frac{35(0.7\ \text{m})}{(2.387\times10^9)^{1/4}} = 0.1108\ \text{m}$$

which is satisfied. That is, the Nusselt number relation for a vertical plate can be used for side surfaces.

$$\text{Ra} = \text{GrPr} = (2.387\times10^9)(0.7161) = 1.709\times10^9$$

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\Pr}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(1.709\times10^9)^{1/6}}{\left[1+\left(\frac{0.492}{0.7161}\right)^{9/16}\right]^{8/27}}\right\}^2 = 145.2$$

$$h = \frac{k}{L}Nu = \frac{0.02931\ \text{W/m.°C}}{0.7\ \text{m}}(145.2) = 6.080\ \text{W/m}^2.\text{°C}$$

$$A_s = \pi DL + \pi D^2/4 = \pi(0.32\ \text{m})(0.7\ \text{m}) + \pi(0.32\ \text{m})^2/4 = 0.7841\ \text{m}^2$$

Then the surface temperature of the stove is determined from

$$\dot{Q} = \dot{Q}_{\text{conv}} + \dot{Q}_{\text{rad}} = hA_s(T_s - T_\infty) + \varepsilon\sigma A_s(T_s{}^4 - T_{\text{surr}}{}^4)$$

$$1200\ \text{W} = (6.080\ \text{W/m}^2.\text{°C})(0.7841\ \text{m}^2)(T_s - 297) + (0.85)(0.7841\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)(T_s{}^4 - 290^4)$$

$$\longrightarrow T_s = 400.6\ \text{K} = \mathbf{127.6°C}$$

The amount of coal used is determined from

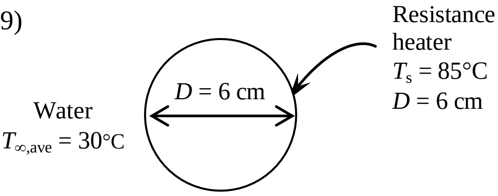
$$Q = \dot{Q}\Delta t = (1.2\ \text{kJ/s})(14\ \text{h/day}\times3600\ \text{s/h}) = 60{,}480\ \text{kJ}$$

$$m_{\text{coal}} = \frac{Q/\eta}{HV} = \frac{(60{,}480\ \text{kJ})/0.65}{30{,}000\ \text{kJ/kg}} = \mathbf{3.102\ kg}$$

9-49 Water in a tank is to be heated by a spherical heater. The heating time is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The temperature of the outer surface of the sphere is constant.

Properties Using the average temperature for water (15+45)/2=30 as the fluid temperature, the properties of water at the film temperature of $(T_s+T_\infty)/2$ = (85+30)/2 = 57.5°C are (Table A-9)



$$k = 0.6515 \text{ W/m.°C}$$

$$\upsilon = 0.474\times10^{-6} \text{ m}^2\text{/s}$$

$$\text{Pr} = 3.12$$

$$\beta = 0.501\times10^{-3} \text{ K}^{-1}$$

Also, the properties of water at 30°C are (Table A-9)

$$\rho = 996 \text{ kg/m}^3 \text{ and } C_p = 4178 \text{ J/kg.°C}$$

Analysis The characteristic length in this case is $L_c = D$ = 0.06 m. Then,

$$\text{Ra} = \frac{g\beta(T_s - T_\infty)D^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.501\times10^{-3} \text{ K}^{-1})(85-30 \text{ K})(0.06 \text{ m})^3}{(0.474\times10^{-6} \text{ m}^2\text{/s})^2}(3.12) = 8.108\times10^8$$

$$Nu = 2 + \frac{0.589Ra^{1/4}}{\left[1+\left(0.469/\text{Pr}\right)^{9/16}\right]^{4/9}} = 2 + \frac{0.589(8.108\times10^8)^{1/4}}{\left[1+\left(0.469/3.12\right)^{9/16}\right]^{4/9}} = 89.14$$

$$h = \frac{k}{D}Nu = \frac{0.6515 \text{ W/m.°C}}{0.06 \text{ m}}(89.14) = 967.9 \text{ W/m}^2\text{.°C}$$

$$A_s = \pi D^2 = \pi(0.06 \text{ m})^2 = 0.01131 \text{ m}^2$$

The rate of heat transfer by convection is

$$\dot{Q}_{\text{conv}} = hA_s(T_s - T_\infty) = (967.9 \text{ W/m}^2\text{.°C})(0.01131 \text{ m}^2)(85-30) = 602.1 \text{ W}$$

The mass of water in the container is

$$m = \rho V = (996 \text{ kg/m}^3)(0.040 \text{ m}^3) = 39.84 \text{ kg}$$

The amount of heat transfer to the water is

$$Q = mC_p(T_2 - T_1) = (39.84 \text{ kg})(4178 \text{ J/kg.°C})(45\text{-}15)\text{°C} = 4.994\times10^6 \text{ J}$$

Then the time the heater should be on becomes

$$\Delta t = \frac{Q}{\dot{Q}} = \frac{4.994\times10^6 \text{ J}}{602.1 \text{ J/s}} = 8294 \text{ s} = \mathbf{2.304 \text{ hours}}$$

Combined Natural and Forced Convection

9-72C In combined natural and forced convection, the natural convection is negligible when $Gr/\mathrm{Re}^2 < 0.1$. Otherwise it is not.

9-73C In assisting or transverse flows, natural convection enhances forced convection heat transfer while in opposing flow it hurts forced convection.

9-74C When neither natural nor forced convection is negligible, it is not correct to calculate each separately and to add them to determine the total convection heat transfer. Instead, the correlation

$$\mathrm{Nu}_{\text{combined}} = \left(\mathrm{Nu}^n_{\text{forced}} + \mathrm{Nu}^n_{\text{natural}}\right)^{1/n}$$

based on the experimental studies should be used.

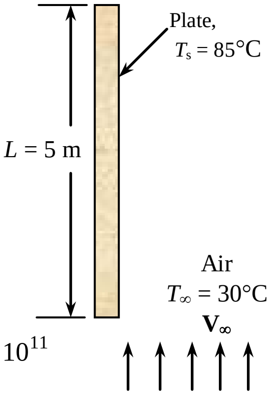
9-75 A vertical plate in air is considered. The forced motion velocity above which natural convection heat transfer from the plate is negligible is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The atmospheric pressure at that location is 1 atm.

Properties The properties of air at 1 atm and 1 atm and the film temperature of $(T_s+T_\infty)/2 = (85+30)/2 = 57.5°\text{C}$ are (Table A-15)

$$\upsilon = 1.871\times10^{-5}\ \text{m}^2/\text{s}$$

$$\beta = \frac{1}{T_f} = \frac{1}{(57.5+273)\text{K}} = 0.003026\ \text{K}^{-1}$$



Analysis The characteristic length is the height of the plate, $L_c = L = 5$ m. The Grashof and Reynolds numbers are

$$Gr = \frac{g\beta(T_s - T_\infty)L^3}{\upsilon^2} = \frac{(9.81\ \text{m/s}^2)(0.003026\ \text{K}^{-1})(85-30\ \text{K})(5\ \text{m})^3}{(1.871\times10^{-5}\ \text{m}^2/\text{s})^2} = 5.829\times10^{11}$$

$$\mathrm{Re} = \frac{V_\infty L}{\upsilon} = \frac{V_\infty(5\ \text{m})}{1.871\times10^{-5}\ \text{m}^2/\text{s}} = 2.67\times10^5 V_\infty$$

and the forced motion velocity above which natural convection heat transfer from this plate is negligible is

$$\frac{Gr}{\mathrm{Re}^2} = 0.1 \longrightarrow \frac{5.829\times10^{11}}{(2.67\times10^5 V_\infty)^2} = 0.1 \longrightarrow V_\infty = \mathbf{9.04\ m/s}$$

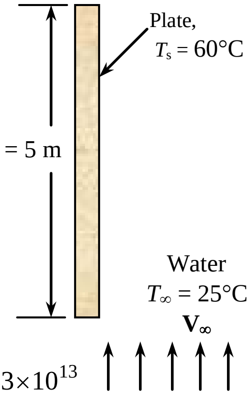
T_s [C]

9-77 A vertical plate in water is considered. The forced motion velocity above which natural convection heat transfer from the plate is negligible is to be determined.



Assumptions **1** Steady operating conditions exist.

Properties The properties of water at the film temperature of $(T_s+T_\infty)/2 = (60+25)/2 = 42.5°C$ are (Table A-15)

$$\upsilon = 0.65\times10^{-6}\ \text{m}^2/\text{s}$$
$$\beta = 0.00040\ \text{K}^{-1}$$

Analysis The characteristic length is the height of the plate $L_c = L = 5$ m. The Grashof and Reynolds numbers are

$$Gr = \frac{g\beta(T_s - T_\infty)L^3}{\upsilon^2} = \frac{(9.81\,\text{m/s}^2)(0.0004\,\text{K}^{-1})(60-25\,\text{K})(5\,\text{m})^3}{(0.65\times10^{-6}\ \text{m}^2/\text{s})^2} = 4.063\times10^{13}$$

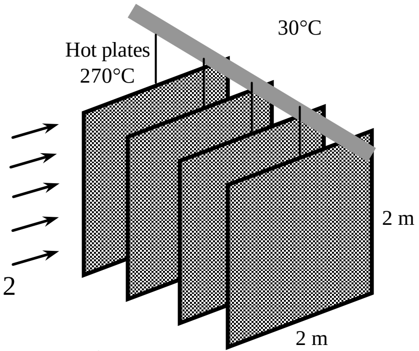
$$\text{Re} = \frac{V_\infty L}{\upsilon} = \frac{V_\infty(5\,\text{m})}{0.65\times10^{-6}\ \text{m}^2/\text{s}} = 4.6\times10^6 V_\infty$$

and the forced motion velocity above which natural convection heat transfer from this plate is negligible is

$$\frac{Gr}{\text{Re}^2} = 0.1 \longrightarrow \frac{4.063\times10^{13}}{(4.6\times10^6 V_\infty)^2} = 0.1 \longrightarrow V_\infty = \mathbf{2.62\,m/s}$$

9-78 Thin square plates coming out of the oven in a production facility are cooled by blowing ambient air horizontally parallel to their surfaces. The air velocity above which the natural convection effects on heat transfer are negligible is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The atmospheric pressure at that location is 1 atm.



Properties The properties of air at 1 atm and 1 atm and the film temperature of $(T_s+T_\infty)/2 = (270+30)/2 = 150°C$ are (Table A-15)

$$\upsilon = 2.859\times10^{-5}\ \text{m}^2/\text{s}$$
$$\beta = \frac{1}{T_f} = \frac{1}{(150+273)\text{K}} = 0.002364\ \text{K}^{-1}$$

Analysis The characteristic length is the height of the plate $L_c = L = 2$ m. The Grashof and Reynolds numbers are

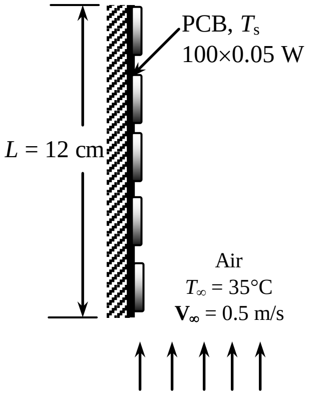
$$Gr = \frac{g\beta(T_s - T_\infty)L^3}{\upsilon^2} = \frac{(9.81\,\text{m/s}^2)(0.002364\,\text{K}^{-1})(270-30\,\text{K})(2\,\text{m})^3}{(2.859\times10^{-5}\ \text{m}^2/\text{s})^2} = 5.447\times10^{10}$$

$$\text{Re} = \frac{V_\infty L}{\upsilon} = \frac{V_\infty(2\,\text{m})}{2.859\times10^{-5}\ \text{m}^2/\text{s}} = 6.995\times10^4 V_\infty$$

and the forced motion velocity above which natural convection heat transfer from this plate is negligible is

$$\frac{Gr}{\text{Re}^2} = 0.1 \longrightarrow \frac{5.447\times10^{10}}{(6.995\times10^4 V_\infty)^2} = 0.1 \longrightarrow V_\infty = \mathbf{10.6\ m/s}$$

9-79 A circuit board is cooled by a fan that blows air upwards. The average temperature on the surface of the circuit board is to be determined for two cases.



Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The atmospheric pressure at that location is 1 atm.

Properties The properties of air at 1 atm and 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2$ = (60+35)/2 = 47.5°C are (Table A-15)

$$k = 0.02717 \text{ W/m.°C}$$
$$\upsilon = 1.774\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7235$$
$$\beta = \frac{1}{T_f} = \frac{1}{(47.5+273)\text{K}} = 0.00312 \text{ K}^{-1}$$

Analysis We assume the surface temperature to be 60°C. We will check this assumption later on and repeat calculations with a better assumption, if necessary. The characteristic length in this case is the length of the board in the flow (vertical) direction, $L_c = L$ = 0.12 m. Then the Reynolds number becomes

$$\text{Re} = \frac{V_\infty L}{\upsilon} = \frac{(0.5 \text{ m/s})(0.12 \text{ m})}{1.774\times10^{-5} \text{ m}^2\text{/s}} = 3383$$

which is less than critical Reynolds number (5×10^5). Therefore the flow is laminar and the forced convection Nusselt number and h are determined from

$$Nu = \frac{hL}{k} = 0.664\,\text{Re}^{0.5}\,\text{Pr}^{1/3} = 0.664(3383)^{0.5}(0.7235)^{1/3} = 34.67$$

$$h = \frac{k}{L}Nu = \frac{0.02717 \text{ W/m.°C}}{0.12 \text{ m}}(34.67) = 7.85 \text{ W/m}^2\text{.°C}$$

$$A_s = L\times W = (0.12 \text{ m})(0.2 \text{ m}) = 0.024 \text{ m}^2$$

Then,

$$\dot{Q} = hA_s(T_s - T_\infty) \longrightarrow T_s = T_\infty + \frac{\dot{Q}}{hA_s} = 35°\text{C} + \frac{(100)(0.05 \text{ W})}{(7.85 \text{ W/m}^2\text{.°C})(0.024 \text{ m}^2)} = \mathbf{61.5°C}$$

which is sufficiently close to the assumed value in the evaluation of properties. Therefore, there is no need to repeat calculations.

(b) The Rayleigh number is

$$Ra = \frac{g\beta(T_s - T_\infty)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.00312 \text{ K}^{-1})(60-35 \text{ K})(0.12 \text{ m})^3}{(1.774\times10^{-5} \text{ m}^2\text{/s})^2}(0.7235) = 3.041\times10^6$$

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(3.041\times10^6)^{1/6}}{\left[1+\left(\frac{0.492}{0.7235}\right)^{9/16}\right]^{8/27}}\right\}^2 = 22.42$$

This is an assisting flow and the combined Nusselt number is determined from

$$Nu_{combined} = (Nu_{forced}{}^n + Nu_{natural}{}^n)^{1/n} = (34.67^3 + 22.42^3)^{1/3} = 37.55$$

Then, $$h = \frac{k}{L}Nu_{combined} = \frac{0.02717 \text{ W/m.°C}}{0.12 \text{ m}}(37.55) = 8.502 \text{ W/m}^2\text{.°C}$$

and $$\dot{Q} = hA_s(T_s - T_\infty) \longrightarrow T_s = T_\infty + \frac{\dot{Q}}{hA_s} = 35°\text{C} + \frac{(100)(0.05\ \text{W})}{(8.502\ \text{W/m}^2.°\text{C})(0.024\ \text{m}^2)} = \mathbf{59.5°C}$$

Therefore, natural convection lowers the surface temperature in this case by about 2°C.

Special Topic: Heat Transfer Through Windows

9-80C Windows are considered in three regions when analyzing heat transfer through them because the structure and properties of the frame are quite different than those of the glazing. As a result, heat transfer through the frame and the edge section of the glazing adjacent to the frame is two-dimensional. Even in the absence of solar radiation and air infiltration, heat transfer through the windows is more complicated than it appears to be. Therefore, it is customary to consider the windows in three regions when analyzing heat transfer through them: (1) the *center-of-glass*, (2) the *edge-of-glass*, and (3) the *frame* regions. When the heat transfer coefficient for all three regions are known, the overall U-value of the window is determined from

$$U_{\text{window}} = (U_{\text{center}} A_{\text{center}} + U_{\text{edge}} A_{\text{edge}} + U_{\text{frame}} A_{\text{frame}}) / A_{\text{window}}$$

where A_{window} is the window area, and A_{center}, A_{edge}, and A_{frame} are the areas of the center, edge, and frame sections of the window, respectively, and U_{center}, U_{edge}, and U_{frame} are the heat transfer coefficients for the center, edge, and frame sections of the window.

9-81C Of the three similar double pane windows with air gab widths of 5, 10, and 20 mm, the U-factor and thus the rate of heat transfer through the window will be a minimum for the window with 10-mm air gab, as can be seen from Fig. 9-44.

9-82C In an ordinary double pane window, about half of the heat transfer is by radiation. A practical way of reducing the radiation component of heat transfer is to reduce the emissivity of glass surfaces by coating them with low-emissivity (or “low-e”) material.

9-83C When a thin polyester film is used to divide the 20-mm wide air of a double pane window space into two 10-mm wide layers, both (*a*) convection and (*b*) radiation heat transfer through the window will be reduced.

9-84C When a double pane window whose air space is flashed and filled with argon gas, (*a*) convection heat transfer will be reduced but (*b*) radiation heat transfer through the window will remain the same.

9-85C The heat transfer rate through the glazing of a double pane window is higher at the edge section than it is at the center section because of the two-dimensional effects due to heat transfer through the frame.

9-86C The *U*-factors of windows with aluminum frames will be highest because of the higher conductivity of aluminum. The U-factors of wood and vinyl frames are comparable in magnitude.

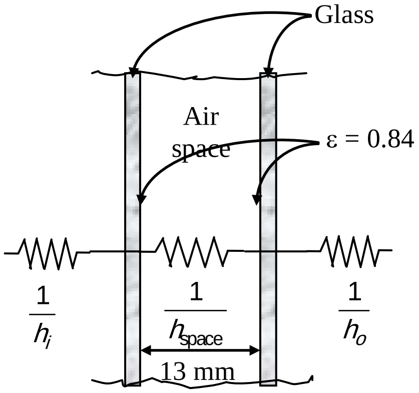
9-87 The U-factor for the center-of-glass section of a double pane window is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat transfer through the window is one-dimensional. **3** The thermal resistance of glass sheets is negligible.

Properties The emissivity of clear glass is given to be 0.84. The values of h_i and h_o for winter design conditions are h_i = 8.29 W/m^2.°C and h_o = 34.0 W/m^2.°C (from the text).

Analysis Disregarding the thermal resistance of glass sheets, which are small, the U-factor for the center region of a double pane window is determined from

$$\frac{1}{U_{\text{center}}} \cong \frac{1}{h_i} + \frac{1}{h_{\text{space}}} + \frac{1}{h_o}$$



where h_i, h_{space}, and h_o are the heat transfer coefficients at the inner surface of window, the air space between the glass layers, and the outer surface of the window, respectively. The effective emissivity of the air space of the double pane window is

$$\varepsilon_{\text{effective}} = \frac{1}{1/\varepsilon_1 + 1/\varepsilon_2 - 1} = \frac{1}{1/0.84 + 1/0.84 - 1} = 0.72$$

For this value of emissivity and an average air space temperature of 10°C with a temperature difference across the air space to be 15°C, we read h_{space} = 5.7 W/m^2.°C from Table 9-3 for 13-mm thick air space. Therefore,

$$\frac{1}{U_{\text{center}}} = \frac{1}{8.29} + \frac{1}{5.7} + \frac{1}{34.0} \rightarrow U_{\text{center}} = \mathbf{3.07\ W/m^2.°C}$$

Discussion The overall U-factor of the window will be higher because of the edge effects of the frame.

9-88 The rate of heat loss through an double-door wood framed window and the inner surface temperature are to be determined for the cases of single pane, double pane, and low-e triple pane windows.

Assumptions **1** Steady operating conditions exist. **2** Heat transfer through the window is one-dimensional. **3** Thermal properties of the windows and the heat transfer coefficients are constant. **4** Infiltration heat losses are not considered.

Properties The U-factors of the windows are given in Table 9-6.

Analysis The rate of heat transfer through the window can be determined from

$$\dot{Q}_{\text{window}} = U_{\text{overall}} A_{\text{window}} (T_i - T_o)$$

where T_{i} and T_{o} are the indoor and outdoor air temperatures, respectively, U_{overall} is the U-factor (the overall heat transfer coefficient) of the window, and A_{window} is the window area which is determined to be

$$A_{window} = \text{Height} \times \text{Width} = (1.2\text{ m})(1.8\text{ m}) = 2.16\text{ m}^2$$

The U-factors for the three cases can be determined directly from Table 9-6 to be 5.57, 2.86, and 1.46 W/m^2.°C, respectively. Also, the inner surface temperature of the window glass can be determined from Newton's law,

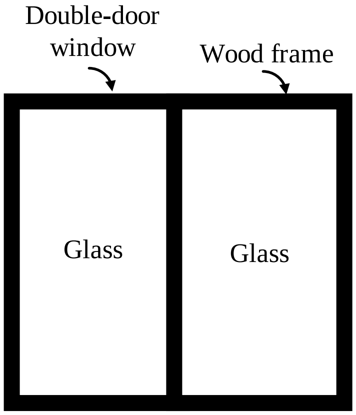
$$\dot{Q}_{\text{window}} = h_i A_{\text{window}} (T_i - T_{\text{glass}}) \rightarrow T_{\text{glass}} = T_i - \frac{\dot{Q}_{\text{window}}}{h_i A_{\text{window}}}$$

where h_{i} is the heat transfer coefficient on the inner surface of the window which is determined from Table 9-5 to be h_{i} = 8.3 W/m^2.°C. Then the rate of heat loss and the interior glass temperature for each case are determined as follows:

(*a*) Single glazing:

$$\dot{Q}_{\text{window}} = (5.57\text{ W/m}^2.°\text{C})(2.16\text{ m}^2)[20-(-8)]°\text{C} = \mathbf{337\ W}$$

$$T_{\text{glass}} = T_i - \frac{\dot{Q}_{\text{window}}}{h_i A_{\text{window}}} = 20°\text{C} - \frac{337\text{ W}}{(8.29\text{ W/m}^2.°\text{C})(2.16\text{ m}^2)} = \mathbf{1.2°C}$$



(*b*) Double glazing (13 mm air space):

$$\dot{Q}_{\text{window}} = (2.86\text{ W/m}^2.°\text{C})(2.16\text{ m}^2)[20-(-8)]°\text{C} = \mathbf{173\ W}$$

$$T_{\text{glass}} = T_i - \frac{\dot{Q}_{\text{window}}}{h_i A_{\text{window}}} = 20°\text{C} - \frac{173\text{ W}}{(8.29\text{ W/m}^2.°\text{C})(2.16\text{ m}^2)} = \mathbf{10.3°C}$$

(*c*) Triple glazing (13 mm air space, low-e coated):

$$\dot{Q}_{\text{window}} = (1.46\text{ W/m}^2.°\text{C})(2.16\text{ m}^2)[20-(-8)]°\text{C} = \mathbf{88.3\ W}$$

$$T_{\text{glass}} = T_i - \frac{\dot{Q}_{window}}{h_i A_{window}} = 20 - \frac{88.3\text{ W}}{(8.3\text{ W/m}^2.°\text{C})(2.16\text{ m}^2)} = \mathbf{15.1°C}$$

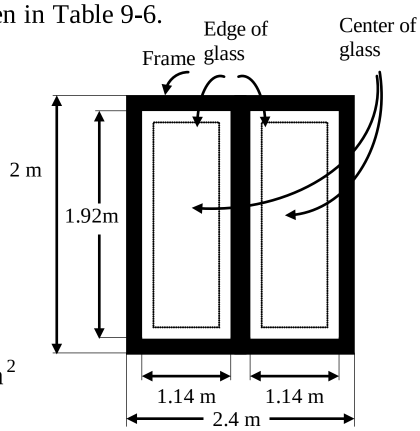
Discussion Note that heat loss through the window will be reduced by 49 percent in the case of double glazing and by 74 percent in the case of triple glazing relative to the single glazing case. Also, in the case of single glazing, the low inner glass surface temperature will cause considerable discomfort in the occupants because of the excessive heat loss from the body by radiation. It is raised from 1.2°C to 10.3°C in the case of double glazing and to 15.1°C in the case of triple glazing.

9-89 The overall U-factor for a double-door type window is to be determined, and the result is to be compared to the value listed in Table 9-6.

Assumptions **1** Steady operating conditions exist. **2** Heat transfer through the window is one-dimensional.

Properties The U-factors for the various sections of windows are given in Table 9-6.

Analysis The areas of the window, the glazing, and the frame are



$$A_{\text{window}} = \text{Height} \times \text{width} = (2\text{ m})(2.4\text{ m}) = 4.80\text{ m}^2$$

$$A_{\text{glazing}} = 2 \times (\text{Height} \times \text{width}) = 2(1.92\text{ m})(1.14\text{ m}) = 4.38\text{ m}^2$$

$$A_{\text{frame}} = A_{\text{window}} - A_{\text{glazing}} = 4.80 - 4.38 = 0.42\text{ m}^2$$

The edge-of-glass region consists of a 6.5-cm wide band around the perimeter of the glazings, and the areas of the center and edge sections of the glazing are determined to be

$$A_{\text{center}} = 2(\text{Height} \times \text{Width}) = 2(1.92 - 0.13\text{ m})(1.14 - 0.13\text{ m}) = 3.62\text{ m}^2$$

$$A_{\text{edge}} = A_{\text{glazing}} - A_{\text{center}} = 4.38 - 3.62 = 0.76\text{ m}^2$$

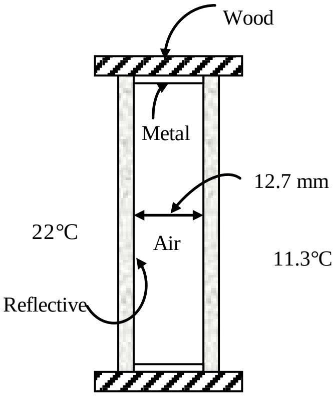
The U-factor for the frame section is determined from Table 9-4 to be U_{frame} = 2.8 W/m^2.°C. The U-factor for the center and edge sections are determined from Table 9-6 to be U_{center} = 2.78 W/m^2.°C and U_{edge} =3.40 W/m^2.°C. Then the overall U-factor of the entire window becomes

$$\begin{aligned} U_{\text{window}} &= (U_{\text{center}} A_{\text{center}} + U_{\text{edge}} A_{\text{edge}} + U_{\text{frame}} A_{\text{frame}}) / A_{\text{window}} \\ &= (2.78 \times 3.62 + 3.40 \times 0.76 + 2.8 \times 0.42) / 4.80 \\ &= \mathbf{2.88\ W/m^2.°C} \end{aligned}$$

Discussion The overall U-factor listed in Table 9-6 for the specified type of window is 2.86 W/m^2.°C, which is sufficiently close to the value obtained above.

9-90 The windows of a house in Atlanta are of double door type with wood frames and metal spacers. The average rate of heat loss through the windows in winter is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat transfer through the window is one-dimensional. **3** Thermal properties of the windows and the heat transfer coefficients are constant. **4** Infiltration heat losses are not considered.



Properties The U-factor of the window is given in Table 9-6 to be 2.13 W/m^2.°C.

Analysis The rate of heat transfer through the window can be determined from

$$\dot{Q}_{\text{window, ave}} = U_{\text{overall}} A_{\text{window}} (T_i - T_{o,\text{ave}})$$

where T_i and T_o are the indoor and outdoor air temperatures, respectively, U_overall is the U-factor (the overall heat transfer coefficient) of the window, and A_window is the window area. Substituting,

$$\dot{Q}_{\text{window, ave}} = (2.13\ \text{W/m}^2 \cdot {}^\circ\text{C})(20\ \text{m}^2)(22 - 11.3)^\circ\text{C} = \mathbf{456\ W}$$

Discussion This is the “average” rate of heat transfer through the window in winter in the absence of any infiltration.

9-91E The *R*-value of the common double door windows that are double pane with 1/4-in of air space and have aluminum frames is to be compared to the *R*-value of *R*-13 wall. It is also to be determined if more heat is transferred through the windows or the walls.

Assumptions **1** Steady operating conditions exist. **2** Heat transfer through the window is one-dimensional. **3** Thermal properties of the windows and the heat transfer coefficients are constant. **4** Infiltration heat losses are not considered.

Properties The U-factor of the window is given in Table 9-6 to be 4.55×0.176 = 0.801 Btu/h.ft^2.°F.

Analysis The *R*-value of the windows is simply the inverse of its *U*-factor, and is determined to be

$$R_{\text{window}} = \frac{1}{U} = \frac{1}{0.801\,\text{Btu/h}\cdot\text{ft}^2\cdot°\text{F}} = 1.25\,\text{h}\cdot\text{ft}^2\cdot°\text{F/Btu}$$

which is less than 13. Therefore, the *R*-value of a double pane window is **much less** than the *R*-value of an *R*-13 wall.

Now consider a 1-ft^2 section of a wall. The solid wall and the window areas of this section are A_{wall} = 0.8 ft^2 and A_{window} = 0.2 ft^2. Then the rates of heat transfer through the two sections are determined to be

$$\dot{Q}_{\text{wall}} = U_{wall} A_{\text{wall}}(T_i - T_o) = A_{\text{wall}} \frac{T_i - T_o}{\text{R} - \text{value, wall}} = (0.8\,\text{ft}^2)\frac{\Delta T(°\text{F})}{(13\,\text{h.ft}^2.°\text{F/Btu}} = 0.0615\Delta T \text{ Btu/h}$$

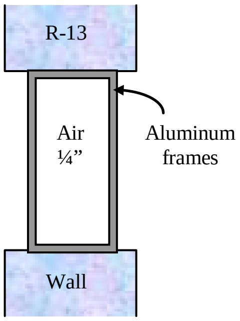
$$\dot{Q}_{\text{window}} = U_{\text{window}} A_{\text{window}}(T_i - T_o) = A_{\text{window}} \frac{T_i - T_o}{\text{R} - \text{value}} = (0.2\,\text{ft}^2)\frac{\Delta T(°\text{F})}{(1.25\,\text{h.ft}^2.°\text{F/Btu}} = 0.160\Delta T \text{ Btu/h}$$

Therefore, the rate of heat transfer through a double pane window is **much more** than the rate of heat transfer through an *R*-13 wall.

Discussion The ratio of heat transfer through the wall and through the window is

$$\frac{\dot{Q}_{\text{window}}}{\dot{Q}_{\text{wall}}} = \frac{0.160\,\text{Btu/h}}{0.0615\,\text{Btu/h}} = 2.60$$

Therefore, 2.6 times more heat is lost through the windows than through the walls although the windows occupy only 20% of the wall area.



9-92 The overall U-factor of a window is given to be U = 2.76 W/m^2.°C for 12 km/h winds outside. The new U-factor when the wind velocity outside is doubled is to be determined.

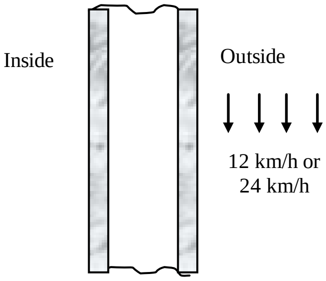
Assumptions Thermal properties of the windows and the heat transfer coefficients are constant.

Properties The heat transfer coefficients at the outer surface of the window are h_o = 22.7 W/m^2.°C for 12 km/h winds, and h_o = 34.0 W/m^2.°C for 24 km/h winds (from the text).

Analysis The corresponding convection resistances for the outer surfaces of the window are

$$R_{o,\,12\text{ km/h}} = \frac{1}{h_{o,\,12\text{ km/h}}} = \frac{1}{22.7\text{ W/m}^2\cdot°\text{C}} = 0.044\text{ m}^2\cdot°\text{C/W}$$

$$R_{o,\,24\text{ km/h}} = \frac{1}{h_{o,\,24\text{ km/h}}} = \frac{1}{34.0\text{ W/m}^2\cdot°\text{C}} = 0.029\text{ m}^2\cdot°\text{C/W}$$



Also, the R-value of the window at 12 km/h winds is

$$R_{\text{window},\,12\text{ km/h}} = \frac{1}{U_{\text{window},\,12\text{ km/h}}} = \frac{1}{2.76\text{ W/m}^2\cdot°\text{C}} = 0.362\text{ m}^2\cdot°\text{C/W}$$

Noting that all thermal resistances are in series, the thermal resistance of the window for 24 km/h winds is determined by replacing the convection resistance for 12 km/h winds by the one for 24 km/h:

$$R_{\text{window},\,24\text{ km/h}} = R_{\text{window},\,12\text{ km/h}} - R_{o,\,12\text{ km/h}} + R_{o,\,24\text{ km/h}} = 0.362 - 0.044 + 0.029 = 0.347\text{ m}^2\cdot°\text{C/W}$$

Then the U-factor for the case of 24 km/h winds becomes

$$U_{\text{window},\,24\text{ km/h}} = \frac{1}{R_{\text{window},\,24\text{ km/h}}} = \frac{1}{0.347\text{ m}^2\cdot°\text{C/W}} = \mathbf{2.88\ W/m^2\cdot°C}$$

Discussion Note that doubling of the wind velocity increases the U-factor only slightly (about 4%) from 2.76 to 2.88 W/m^2.°C.

9-93 The existing wood framed single pane windows of an older house in Wichita are to be replaced by double-door type vinyl framed double pane windows with an air space of 6.4 mm. The amount of money the new windows will save the home owner per month is to be determined.

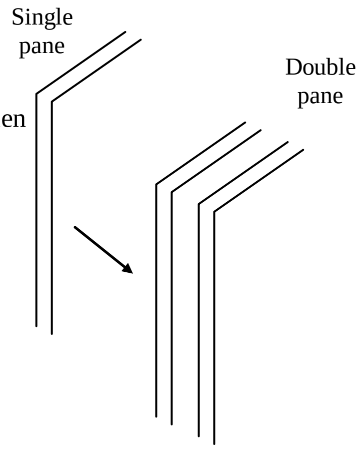
Assumptions **1** Steady operating conditions exist. **2** Heat transfer through the window is one-dimensional. **3** Thermal properties of the windows and the heat transfer coefficients are constant. **4** Infiltration heat losses are not considered.

Properties The U-factors of the windows are 5.57 W/m^2.°C for the old single pane windows, and 3.20 W/m^2.°C. for the new double pane windows (Table 9-6).

Analysis The rate of heat transfer through the window can be determined from

$$Q_{\text{window}} = U_{\text{overall}} A_{\text{window}} (T_i - T_o)$$

where T_i and T_o are the indoor and outdoor air temperatures, respectively, U_{overall} is the U-factor (the overall heat transfer coefficient) of the window, and A_{window} is the window area. Noting that the heaters will turn on only when the outdoor temperature drops below 18°C, the rates of heat transfer due to electric heating for the old and new windows are determined to be



$$\dot{Q}_{\text{window, old}} = (5.57\ \text{W/m}^2.°\text{C})(12\ \text{m}^2)(18-7.1)°\text{C} = 729\ \text{W}$$

$$\dot{Q}_{\text{window, new}} = (3.20\ \text{W/m}^2.°\text{C})(12\ \text{m}^2)(18-7.1)°\text{C} = 419\ \text{W}$$

$$\dot{Q}_{\text{saved}} = \dot{Q}_{\text{window, old}} - \dot{Q}_{\text{window, new}} = 729 - 419 = 310\ \text{W}$$

Then the electrical energy and cost savings per month becomes

$$\text{Energy savings} = \dot{Q}_{\text{saved}} \Delta t = (0.310\ \text{kW})(30 \times 24\ \text{h/month}) = 223\ \text{kWh/month}$$

$$\text{Cost savings} = (\text{Energy savings})(\text{Unit cost of energy}) = (223\ \text{kWh/month})(\$0.07/\text{kWh}) = \mathbf{\$15.62/month}$$

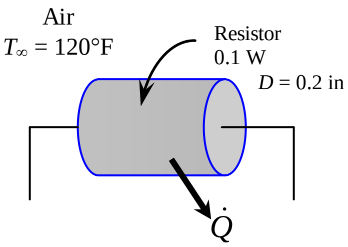
Discussion We would obtain the same result if we used the actual indoor temperature (probably 22°C) for T_i instead of the balance point temperature of 18°C.

Review Problems

9-94E A small cylindrical resistor mounted on the lower part of a vertical circuit board. The approximate surface temperature of the resistor is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** Radiation effects are negligible. **5** Heat transfer through the connecting wires is negligible.

Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2 = (220+120)/2 = 170$°F are (Table A-15E)



$$k = 0.01692 \text{ Btu/h.ft.°F}$$

$$\upsilon = 0.222\times10^{-3} \text{ ft}^2\text{/s}$$

$$\Pr = 0.7161$$

$$\beta = \frac{1}{T_f} = \frac{1}{(170+460)\text{R}} = 0.001587 \text{ R}^{-1}$$

Analysis The solution of this problem requires a trial-and-error approach since the determination of the Rayleigh number and thus the Nusselt number depends on the surface temperature which is unknown. We start the solution process by "guessing" the surface temperature to be 220°F for the evaluation of the properties and h. We will check the accuracy of this guess later and repeat the calculations if necessary. The characteristic length in this case is the diameter of resistor, $L_c = D = 0.2$ in. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)D^3}{\upsilon^2}\Pr = \frac{(32.2 \text{ ft/s}^2)(0.001587 \text{ R}^{-1})(220-120 \text{ R})(0.2/12 \text{ ft})^3}{(0.222\times10^{-3} \text{ ft}^2\text{/s})^2}(0.7161) = 343.8$$

$$Nu = \left\{0.6 + \frac{0.387Ra^{1/6}}{\left[1+\left(0.559/\Pr\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6 + \frac{0.387(343.8)^{1/6}}{\left[1+\left(0.559/0.7161\right)^{9/16}\right]^{8/27}}\right\}^2 = 2.105$$

$$h = \frac{k}{D}Nu = \frac{0.01692 \text{ Btu/h.ft.°F}}{0.2/12 \text{ ft}}(2.105) = 2.138 \text{ Btu/h.ft}^2\text{.°F}$$

$$A_s = \pi DL + 2D^2/4 = \pi(0.2/12 \text{ ft})(0.3/12 \text{ ft}) + 2\pi(0.2/12 \text{ ft})^2/4 = 0.00175 \text{ ft}^2$$

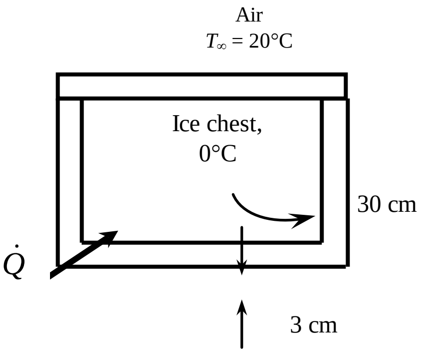
and $$\dot{Q} = hA_s(T_s - T_\infty) \longrightarrow T_s = T_\infty + \frac{\dot{Q}}{hA_s} = 120\text{°F} + \frac{(0.1\times3.412) \text{ Btu/h}}{(2.138 \text{ Btu/h.ft}^2\text{.°F})(0.00175 \text{ ft}^2)} = \mathbf{211.5°F}$$

which is sufficiently close to the assumed temperature for the evaluation of properties. Therefore, there is no need to repeat calculations.

9-95 An ice chest filled with ice at 0°C is exposed to ambient air. The time it will take for the ice in the chest to melt completely is to be determined for natural and forced convection cases.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** Heat transfer from the base of the ice chest is disregarded. **4** Radiation effects are negligible. **5** Heat transfer coefficient is the same for all surfaces considered. **6** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2 = (15+20)/2 = 17.5$°C are (Table A-15)



$$k = 0.02495\ \text{W/m.°C}$$
$$\upsilon = 1.493\times10^{-5}\ \text{m}^2\text{/s}$$
$$\text{Pr} = 0.7316$$
$$\beta = \frac{1}{T_f} = \frac{1}{(17.5+273)\text{K}} = 0.003442\ \text{K}^{-1}$$

Analysis The solution of this problem requires a trial-and-error approach since the determination of the Rayleigh number and thus the Nusselt number depends on the surface temperature which is unknown. We start the solution process by "guessing" the surface temperature to be 15°C for the evaluation of the properties and *h*. We will check the accuracy of this guess later and repeat the calculations if necessary. The characteristic length for the side surfaces is the height of the chest, $L_c = L = 0.3$ m Then,

$$Ra = \frac{g\beta(T_\infty - T_s)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81\,\text{m/s}^2)(0.003442\,\text{K}^{-1})(20-15\,\text{K})(0.3\,\text{m})^3}{(1.493\times10^{-5}\ \text{m}^2\text{/s})^2}(0.7316) = 1.495\times10^7$$

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(1.495\times10^7)^{1/6}}{\left[1+\left(\frac{0.492}{0.7316}\right)^{9/16}\right]^{8/27}}\right\}^2 = 35.15$$

$$h = \frac{k}{L}Nu = \frac{0.02495\,\text{W/m.°C}}{0.3\,\text{m}}(35.15) = 2.923\,\text{W/m}^2\text{.°C}$$

The heat transfer coefficient at the top surface can be determined similarly. However, the top surface constitutes only about one-fourth of the heat transfer area, and thus we can use the heat transfer coefficient for the side surfaces for the top surface also for simplicity. The heat transfer surface area is

$$A_s = 4(0.3\,\text{m})(0.4\,\text{m}) + (0.4\,\text{m})(0.4\,\text{m}) = 0.64\,\text{m}^2$$

Then the rate of heat transfer becomes

$$\dot{Q} = \frac{T_\infty - T_{s,i}}{R_{wall} + R_{conv,o}} = \frac{T_\infty - T_{s,i}}{\frac{L}{kA_s} + \frac{1}{hA_s}} = \frac{(20-0)\text{°C}}{\frac{0.03\,\text{m}}{(0.033\,\text{W/m.°C})(0.64\,\text{m}^2)} + \frac{1}{(2.923\,\text{W/m}^2\text{.°C})(0.64\,\text{m}^2)}} = 10.23\,\text{W}$$

The outer surface temperature of the ice chest is determined from Newton's law of cooling to be

$$\dot{Q} = hA_s(T_\infty - T_s) \to T_s = T_\infty - \frac{\dot{Q}}{hA_s} = 20\text{°C} - \frac{10.4\,\text{W}}{(2.923\,\text{W/m}^2\text{.C})(0.64\,\text{m}^2)} = 14.53\text{°C}$$

which is almost identical to the assumed value of 15°C used in the evaluation of properties and *h*. Therefore, there is no need to repeat the calculations. Then the rate at which the ice will melt becomes

$$\dot{Q}=\dot{m}h_{if}\rightarrow \dot{m}=\frac{\dot{Q}}{h_{if}}=\frac{10.23\times 10^{-3}\text{ kJ/s}}{333.7\text{ kJ/kg}}=3.066\times 10^{-5}\text{ kg/s}$$

Therefore, the melting of the ice in the chest completely will take

$$m=\dot{m}\Delta t\longrightarrow \Delta t=\frac{m}{\dot{m}}=\frac{30\text{ kg}}{3.066\times 10^{-5}\text{ kg/s}}=9.786\times 10^{5}\text{ s}=\mathbf{271.8\,h}=\mathbf{11.3\,days}$$

(b) The temperature drop across the styrofoam will be much greater in this case than that across thermal boundary layer on the surface. Thus we assume outer surface temperature of the styrofoam to be $19\,^\circ\text{C}$. Radiation heat transfer will be neglected. The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2$ = (19+20)/2 = 19.5°C are (Table A-15)

$$k=0.0251\text{ W/m.°C}$$
$$\upsilon=1.512\times 10^{-5}\text{ m}^2\text{/s}$$
$$\Pr=0.7311$$
$$\beta=\frac{1}{T_f}=\frac{1}{(19.5+273)\text{K}}=0.00342\text{ K}^{-1}$$

The characteristic length in this case is the width of the chest, $L_c = W$ =0.4 m. Then,

$$\text{Re}=\frac{V_\infty W}{\upsilon}=\frac{(50\times 1000/3600\text{ m/s})(0.4\text{ m})}{1.512\times 10^{-5}\text{ m}^2\text{/s}}=367{,}538$$

which is less than critical Reynolds number (5×10^5). Therefore the flow is laminar, and the Nusselt number is determined from

$$Nu=\frac{hW}{k}=0.664\,\text{Re}^{0.5}\,\Pr^{1/3}=0.664(367{,}538)^{0.5}(0.7311)^{1/3}=362.6$$

$$h=\frac{k}{W}Nu=\frac{0.0251\text{ W/m.°C}}{0.4\text{ m}}(362.6)=22.76\text{ W/m}^2\text{.°C}$$

Then the rate of heat transfer becomes

$$\dot{Q}=\frac{T_\infty-T_{s,i}}{R_{wall}+R_{conv,o}}=\frac{T_\infty-T_{s,i}}{\frac{L}{kA_s}+\frac{1}{hA_s}}=\frac{(20-0)\text{°C}}{\frac{0.03\text{ m}}{(0.033\text{ W/m.°C})(0.64\text{ m}^2)}+\frac{1}{(22.76\text{ W/m}^2\text{.°C})(0.64\text{ m}^2)}}=13.43\text{ W}$$

The outer surface temperature of the ice chest is determined from Newton's law of cooling to be

$$\dot{Q}=hA_s(T_\infty-T_s)\rightarrow T_s=T_\infty-\frac{\dot{Q}}{hA_s}=20\text{°C}-\frac{13.43\text{ W}}{(22.76\text{ W/m}^2\text{.C})(0.64\text{ m}^2)}=19.1\text{°C}$$

which is almost identical to the assumed value of 19°C used in the evaluation of properties and *h*. Therefore, there is no need to repeat the calculations. Then the rate at which the ice will melt becomes

$$\dot{Q}=\dot{m}h_{if}\rightarrow \dot{m}=\frac{\dot{Q}}{h_{if}}=\frac{13.43\times 10^{-3}\text{ kJ/s}}{333.7\text{ kJ/kg}}=4.025\times 10^{-5}\text{ kg/s}$$

Therefore, the melting of the ice in the chest completely will take

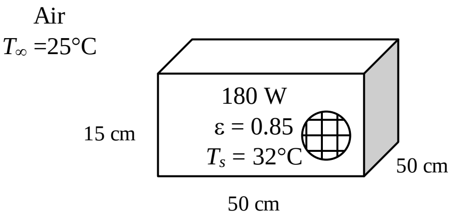
$$m=\dot{m}\Delta t\longrightarrow \Delta t=\frac{m}{\dot{m}}=\frac{30}{4.025\times 10^{-5}}=7.454\times 10^{5}\text{ s}=\mathbf{207.05\,h}=\mathbf{8.6\,days}$$

9-96 An electronic box is cooled internally by a fan blowing air into the enclosure. The fraction of the heat lost from the outer surfaces of the electronic box is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** Heat transfer from the base surface is disregarded. **4** The pressure of air inside the enclosure is 1 atm.

Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2$ = (32+15)/2 = 28.5°C are (Table A-15)

$$k = 0.02577\ \text{W/m.°C}$$
$$\upsilon = 1.594\times10^{-5}\ \text{m}^2\text{/s}$$
$$\Pr = 0.7286$$
$$\beta = \frac{1}{T_f} = \frac{1}{(28.5+273)\text{K}} = 0.003317\ \text{K}^{-1}$$



Analysis Heat loss from the horizontal top surface:

The characteristic length in this case is $L_c = \dfrac{A_s}{p} = \dfrac{(0.5\ \text{m})^2}{2[(0.5\ \text{m})+(0.5\ \text{m})]} = 0.125\ \text{m}$. Then,

$$Ra = \frac{g\beta(T_s-T_\infty)L_c^3}{\upsilon^2}\Pr = \frac{(9.81\ \text{m/s}^2)(0.003317\ \text{K}^{-1})(32-25\ \text{K})(0.125\ \text{m})^3}{(1.594\times10^{-5}\ \text{m}^2\text{/s})^2}(0.7286) = 1.275\times10^6$$

$$Nu = 0.54Ra^{1/4} = 0.54(1.275\times10^6)^{1/4} = 18.15$$

$$h = \frac{k}{L_c}Nu = \frac{0.02577\ \text{W/m.°C}}{0.125\ \text{m}}(18.15) = 3.741\ \text{W/m}^2\text{.°C}$$

$$A_{top} = (0.5\ \text{m})^2 = 0.25\ \text{m}^2$$

and $\dot{Q}_{top} = hA_{top}(T_s-T_\infty) = (3.741\ \text{W/m}^2\text{.°C})(0.25\ \text{m}^2)(32-25)\text{°C} = 6.55\ \text{W}$

Heat loss from vertical side surfaces:

The characteristic length in this case is the height of the box $L_c = L$ =0.15 m. Then,

$$Ra = \frac{g\beta(T_s-T_\infty)L^3}{\upsilon^2}\Pr = \frac{(9.81\ \text{m/s}^2)(0.003317\ \text{K}^{-1})(32-25\ \text{K})(0.15\ \text{m})^3}{(1.594\times10^{-5}\ \text{m}^2\text{/s})^2}(0.7286) = 2.204\times10^6$$

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\Pr}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(2.204\times10^7)^{1/6}}{\left[1+\left(\frac{0.492}{0.7286}\right)^{9/16}\right]^{8/27}}\right\}^2 = 20.55$$

$$h = \frac{k}{L}Nu = \frac{0.02577\ \text{W/m.°C}}{0.15\ \text{m}}(20.55) = 3.530\ \text{W/m}^2\text{.°C}$$

$$A_{side} = 4(0.15\ \text{m})(0.5\ \text{m}) = 0.3\ \text{m}^2$$

and

$$\dot{Q}_{side} = hA_{side}(T_s-T_\infty) = (3.530\ \text{W/m}^2\text{.°C})(0.3\ \text{m}^2)(32-25)\text{°C} = 7.41\ \text{W}$$

The radiation heat loss is

$$\begin{aligned}\dot{Q}_{rad} &= \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)\\ &= (0.85)(0.25+0.3\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\text{.K}^4)[(32+273\ \text{K})^4-(25+273\ \text{K})^4] = 20.34\ \text{W}\end{aligned}$$

Then the fraction of the heat loss from the outer surfaces of the box is determined to be

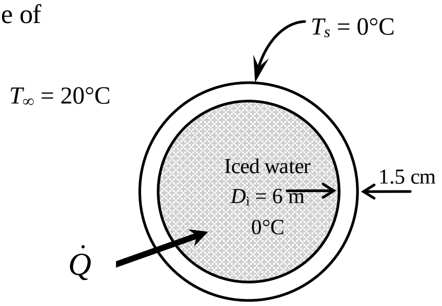
$$f = \frac{(6.55+7.41+20.34)\text{W}}{180\ \text{W}} = 0.1906 = \mathbf{19.1\%}$$

9-97 A spherical tank made of stainless steel is used to store iced water. The rate of heat transfer to the iced water and the amount of ice that melts during a 24-h period are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** Thermal resistance of the tank is negligible. **4** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (0+20)/2 = 10°\text{C}$ are (Table A-15)

$$k = 0.02439 \text{ W/m.°C}$$
$$\upsilon = 1.426\times10^{-5} \text{ m}^2\text{/s}$$
$$\Pr = 0.7336$$
$$\beta = \frac{1}{T_f} = \frac{1}{(10+273)\text{K}} = 0.003534 \text{ K}^{-1}$$



Analysis (*a*) The characteristic length in this case is $L_c = D_o = 6.03$ m. Then,

$$Ra = \frac{g\beta(T_\infty - T_s)D_o^3}{\upsilon^2}\Pr = \frac{(9.81 \text{ m/s}^2)(0.003534 \text{ K}^{-1})(20-0 \text{ K})(6.03 \text{ m})^3}{(1.426\times10^{-5} \text{ m}^2\text{/s})^2}(0.7336) = 5.485\times10^{11}$$

$$Nu = 2 + \frac{0.589Ra^{1/4}}{\left[1+\left(0.469/\Pr\right)^{9/16}\right]^{4/9}} = 2 + \frac{0.589(5.485\times10^{11})^{1/4}}{\left[1+\left(0.469/0.7336\right)^{9/16}\right]^{4/9}} = 394.5$$

$$h = \frac{k}{D_o}Nu = \frac{0.02439 \text{ W/m.°C}}{6.03 \text{ m}}(394.5) = 1.596 \text{ W/m}^2\text{.°C}$$

$$A_s = \pi D_o^2 = \pi(6.03 \text{ m})^2 = 114.2 \text{ m}^2$$

and

$$\dot{Q} = hA_s(T_\infty - T_s) = (1.596 \text{ W/m}^2\text{.°C})(114.2 \text{ m}^2)(20-0)\text{°C} = 3646 \text{ W}$$

Heat transfer by radiation and the total rate of heat transfer are

$$\begin{aligned}\dot{Q}_{rad} &= \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)\\ &= (1)(114.2 \text{ m}^2)(5.67\times10^{-8} \text{ W/m}^2\text{.K}^4)[(20+273 \text{ K})^4 - (0+273 \text{ K})^4] = 11{,}759 \text{ W}\\ \dot{Q}_{total} &= 3646 + 11{,}759 = 15{,}404 \text{ W} \cong \mathbf{15.4\ kW}\end{aligned}$$

(*b*) The total amount of heat transfer during a 24-hour period is

$$Q = \dot{Q}\Delta t = (15.4 \text{ kJ/s})(24 \text{ h/day}\times3600 \text{ s/h}) = 1.331\times10^6 \text{ kJ/day}$$

Then the amount of ice that melts during this period becomes

$$Q = mh_{if} \longrightarrow m = \frac{Q}{h_{if}} = \frac{1.331\times10^6 \text{ kJ}}{333.7 \text{ kJ/kg}} = \mathbf{3988\ kg}$$

9-98 A double-pane window consisting of two layers of glass separated by an air space is considered. The rate of heat transfer through the window and the temperature of its inner surface are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** Radiation effects are negligible. **4** The pressure of air inside the enclosure is 1 atm.

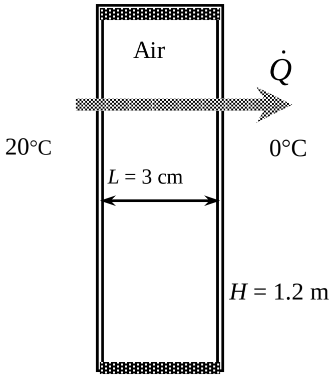
Properties We expect the average temperature of the air gap to be roughly the average of the indoor and outdoor temperatures, and evaluate The properties of air at 1 atm and the average temperature of ($T_{\infty1}$+$T_{\infty2}$)/2 = (20 +0)/2 = 10°C are (Table A-15)

$$k = 0.02439\ \text{W/m.°C}$$

$$\upsilon = 1.426\times10^{-5}\ \text{m}^2\text{/s}$$

$$\text{Pr} = 0.7336$$

$$\beta = \frac{1}{T_f} = \frac{1}{(10+273)\text{K}} = 0.003534\ \text{K}^{-1}$$



Analysis We "guess" the temperature difference across the air gap to be 15°C = 15 K for use in the Ra relation. The characteristic length in this case is the air gap thickness, $L_c = L = 0.03$ m. Then,

$$Ra = \frac{g\beta(T_1-T_2)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81\,\text{m/s}^2)(0.003534\,\text{K}^{-1})(15\,\text{K})(0.03\,\text{m})^3}{(1.426\times10^{-5}\ \text{m}^2\text{/s})^2}(0.7336) = 5.065\times10^4$$

Then the Nusselt number and the heat transfer coefficient are determined to be

$$Nu = 0.42Ra^{1/4}\ \text{Pr}^{0.012}\left(\frac{H}{L}\right)^{-0.3} = 0.42(5.065\times10^4)^{1/4}(0.7336)^{0.012}\left(\frac{1.2\ \text{m}}{0.03\,\text{m}}\right)^{-0.3} = 2.076$$

$$h_{air} = \frac{k}{L}Nu = \frac{0.02439\ \text{W/m.°C}}{0.03\,\text{m}}(2.076) = 1.688\ \text{W/m}^2\text{.°C}$$

Then the rate of heat transfer through this double pane window is determined to be

$$A_s = H\times W = (1.2\ \text{m})(2\ \text{m}) = 2.4\ \text{m}^2$$

$$\dot{Q} = \frac{T_{\infty,i}-T_{\infty,o}}{R_{conv,i}+R_{cond,glasses}+R_{conv,air}+R_{conv,o}} = \frac{T_\infty - T_{s,i}}{\dfrac{1}{h_i A_s}+\dfrac{2t_{\text{glass}}}{k_{glass}A_s}+\dfrac{1}{h_{air}A_s}+\dfrac{1}{h_o A_s}}$$

$$= \frac{20-0}{\dfrac{1}{(10)(2.4)}+\dfrac{2(0.003)}{(0.78)(2.4)}+\dfrac{1}{(1.688)(2.4)}+\dfrac{1}{(25)(2.4)}} = \mathbf{65\ W}$$

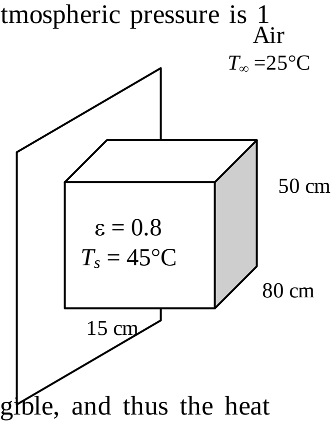
Check: The temperature drop across the air gap is determined from

$$\dot{Q} = hA_s\Delta T \rightarrow \Delta T = \frac{\dot{Q}}{hA_s} = \frac{65\ \text{W}}{(1.688\ \text{W/m}^2\text{.°C})(2.4\ \text{m}^2)} = 16.0°\text{C}$$

which is very close to the assumed value of 15°C used in the evaluation of the Ra number.

9-99 An electric resistance space heater filled with oil is placed against a wall. The power rating of the heater and the time it will take for the heater to reach steady operation when it is first turned on are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** Heat transfer from the back, bottom, and top surfaces are disregarded. **4** The local atmospheric pressure is 1 atm.



Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (45+25)/2 = 35°C$ are (Table A-15)

$$k = 0.02625 \text{ W/m.°C}$$
$$\upsilon = 1.655\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7268$$
$$\beta = \frac{1}{T_f} = \frac{1}{(35+273)\text{K}} = 0.003247 \text{ K}^{-1}$$

Analysis Heat transfer from the top and bottom surfaces are said to be negligible, and thus the heat transfer area in this case consists of the three exposed side surfaces. The characteristic length is the height of the box, $L_c = L = 0.5$ m. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.003247 \text{ K}^{-1})(45-25 \text{ K})(0.5 \text{ m})^3}{(1.655\times10^{-5} \text{ m}^2\text{/s})^2}(0.7268) = 2.114\times10^8$$

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(2.114\times10^8)^{1/6}}{\left[1+\left(\frac{0.492}{0.7268}\right)^{9/16}\right]^{8/27}}\right\}^2 = 76.68$$

$$h = \frac{k}{L}Nu = \frac{0.02625 \text{ W/m.°C}}{0.5 \text{ m}}(76.68) = 4.026 \text{ W/m}^2\text{.°C}$$
$$A_s = (0.5 \text{ m})(0.8 \text{ m}) + 2(0.15 \text{ m})(0.5 \text{ m}) = 0.55 \text{ m}^2$$

and $\dot{Q} = hA_s(T_s - T_\infty) = (4.026 \text{ W/m}^2\text{.°C})(0.55 \text{ m}^2)(45-25)°\text{C} = 44.3 \text{ W}$

The radiation heat loss is

$$\dot{Q}_{rad} = \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4) = (0.8)(0.55 \text{ m}^2)(5.67\times10^{-8} \text{ W/m}^2\text{.K}^4)[(45+273 \text{ K})^4 - (25+273 \text{ K})^4] = 58.4 \text{ W}$$

Then the total rate of heat transfer, thus the power rating of the heater becomes

$$\dot{Q}_{total} = 44.3 + 58.4 = \mathbf{102.7\ W}$$

The specific heat of the oil at the average temperature of the oil is 1943 J/kg.°C. Then the amount of heat transfer needed to raise the temperature of the oil to the steady operating temperature and the time it takes become

$$Q = mC_p(T_2 - T_1) = (45 \text{ kg})(1943 \text{ J/kg.°C})(45-25)°\text{C} = 1.749\times10^6 \text{ J}$$

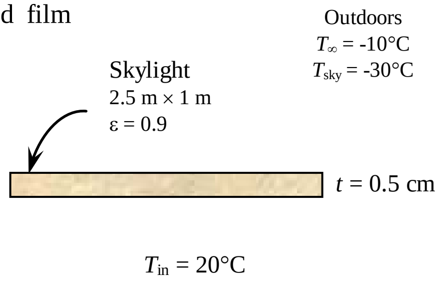
$$Q = \dot{Q}\Delta t \longrightarrow \Delta t = \frac{Q}{\dot{Q}} = \frac{1.749\times10^6 \text{ kJ}}{100 \text{ J/s}} = 17{,}034 \text{ s} = \mathbf{4.73\ h}$$

which is not practical. Therefore, the surface temperature of the heater must be allowed to be higher than 45°C.

9-100 A horizontal skylight made of a single layer of glass on the roof of a house is considered. The rate of heat loss through the skylight is to be determined for two cases.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2$ = (-4-10)/2 = -7°C are (Table A-15)



$$k = 0.0231\ \text{W/m.°C}$$
$$\upsilon = 1.278\times10^{-5}\ \text{m}^2\text{/s}$$
$$\text{Pr} = 0.738$$
$$\beta = \frac{1}{T_f} = \frac{1}{(-7+273)\text{K}} = 0.003759\ \text{K}^{-1}$$

Analysis We assume radiation heat transfer inside the house to be negligible. We start the calculations by "guessing" the glass temperature to be 4°C for the evaluation of the properties and *h*. We will check the accuracy of this guess later and repeat the calculations if necessary. The characteristic length in this case is determined from $L_c = \frac{A_s}{p} = \frac{(1\,\text{m})(2.5\,\text{m})}{2(1\,\text{m}+2.5\,\text{m})} = 0.357\ \text{m}$. Then,

$$Ra = \frac{g\beta(T_1-T_2)L_c^3}{\upsilon^2}\text{Pr} = \frac{(9.81\,\text{m/s}^2)(0.003759\,\text{K}^{-1})[-4-(-10)\,\text{K}](0.357\,\text{m})^3}{(1.278\times10^{-5}\ \text{m}^2\text{/s})^2}(0.738) = 4.553\times10^7$$

$$Nu = 0.15Ra^{1/3} = 0.15(4.553\times10^7)^{1/3} = 53.56$$

$$h_o = \frac{k}{L_c}Nu = \frac{0.0231\,\text{W/m.°C}}{0.357\,\text{m}}(53.56) = 3.465\ \text{W/m}^2\text{.°C}$$

$$A_s = (1\,\text{m})(2.5\,\text{m}) = 2.5\ \text{m}^2$$

Using the assumed value of glass temperature, the radiation heat transfer coefficient is determined to be

$$\begin{aligned} h_{rad} &= \varepsilon\sigma(T_s+T_{sky})(T_s{}^2+T_{sky}{}^2) \\ &= 0.9(5.67\times10^{-8}\ \text{W/m}^2\text{.K}^4)[(-4+273)+(-30+273)][(-4+273)^2+(-30+273)^2]\text{K}^3 \\ &= 3.433\ \text{W/m}^2\text{.K} \end{aligned}$$

Then the combined convection and radiation heat transfer coefficient outside becomes

$$h_{o,combined} = h_o + h_{rad} = 3.465+3.433 = 6.898\ \text{W/m}^2$$

Again we take the glass temperature to be -4°C for the evaluation of the properties and *h* for the inner surface of the skylight. The properties of air at 1 atm and the film temperature of T_f = (-4+20)/2 = 8°C are (Table A-15)

$$k = 0.02424\ \text{W/m.°C}$$
$$\upsilon = 1.409\times10^{-5}\ \text{m}^2\text{/s}$$
$$\text{Pr} = 0.7342$$
$$\beta = \frac{1}{T_f} = \frac{1}{(8+273)\text{K}} = 0.003559\ \text{K}^{-1}$$

The characteristic length in this case is also 0.357 m. Then,

$$Ra = \frac{g\beta(T_1 - T_2)L_c^3}{\upsilon^2}\Pr = \frac{(9.81\,\text{m/s}^2)(0.003559\,\text{K}^{-1})[20-(-4)\,\text{K})(0.357\,\text{m})^3}{(1.409\times10^{-5}\,\text{m}^2/\text{s})^2}(0.7342) = 1.412\times10^8$$

$$Nu = 0.27Ra^{1/4} = 0.27(1.412\times10^8)^{1/4} = 29.43$$

$$h_i = \frac{k}{L_c}Nu = \frac{0.02424\,\text{W/m.°C}}{0.357\,\text{m}}(29.43) = 1.998\,\text{W/m}^2.\text{°C}$$

Using the thermal resistance network, the rate of heat loss through the skylight is determined to be

$$\dot{Q}_{skylight} = \frac{T_{s,i} - T_{\infty,o}}{R_{conv,i} + R_{cond,glas} + R_{combined,o}}$$

$$= \frac{A_s(T_{room} - T_{out})}{\frac{1}{h_i} + \frac{t_{\text{glass}}}{k_{glass}} + \frac{1}{h}} = \frac{(2.5\,\text{m}^2)[20-(-10)]\text{°C}}{\frac{1}{1.998\,\text{W/m}^2.\text{°C}} + \frac{0.005\,\text{m}}{0.78\,\text{W/m.°C}} + \frac{1}{6.898\,\text{W/m}^2.\text{°C}}} = 115\,\text{W}$$

Using the same heat transfer coefficients for simplicity, the rate of heat loss through the roof in the case of R-5.34 construction is determined to be

$$\dot{Q}_{roof} = \frac{T_{s,i} - T_{\infty,o}}{R_{conv,i} + R_{cond} + R_{combined,o}}$$

$$= \frac{A_s(T_{room} - T_{out})}{\frac{1}{h_i} + R_{glass} + \frac{1}{h}} = \frac{(2.5\,\text{m}^2)[20-(-10)]\text{°C}}{\frac{1}{1.998\,\text{W/m}^2.\text{°C}} + 5.34\,\text{m}^2.\text{°C/W} + \frac{1}{6.898\,\text{W/m}^2.\text{°C}}} = 5.36\,\text{W}$$

Therefore, a house loses 115/5.36 ≅ 21 times more heat through the skylights than it does through an insulated wall of the same size.

Using Newton’s law of cooling, the glass temperature corresponding to a heat transfer rate of 115 W is calculated to be –3.3°C, which is sufficiently close to the assumed value of -4°C. Therefore, there is no need to repeat the calculations.

9-101 A solar collector consists of a horizontal copper tube enclosed in a concentric thin glass tube. Water is heated in the tube, and the annular space between the copper and glass tube is filled with air. The rate of heat loss from the collector by natural convection is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** Radiation effects are negligible. **3** The pressure of air in the enclosure is 1 atm.

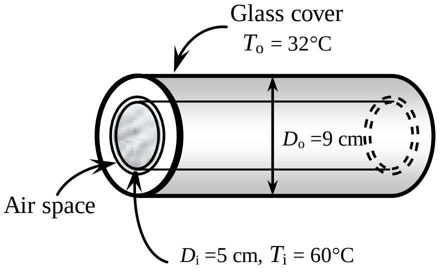
Properties The properties of air at 1 atm and the average temperature of $(T_i+T_o)/2 = (60+32)/2 = 46°\text{C}$ are (Table A-15)

$$k = 0.02706 \text{ W/m.°C}$$

$$\upsilon = 1.759\times10^{-5} \text{ m}^2/\text{s}$$

$$\text{Pr} = 0.7239$$

$$\beta = \frac{1}{T_f} = \frac{1}{(46+273)\text{K}} = 0.003135 \text{ K}^{-1}$$



Analysis The characteristic length in this case is the distance between the two cylinders ,

$$L_c = \frac{D_o - D_i}{2} = \frac{(9-5)\text{ cm}}{2} = 2 \text{ cm}$$

and,

$$Ra = \frac{g\beta(T_i - T_o)L_c^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.003135 \text{ K}^{-1})(60-32 \text{ K})(0.02 \text{ m})^3}{(1.759\times10^{-5} \text{ m}^2/\text{s})^2}(0.7239) = 16{,}106$$

The effective thermal conductivity is

$$F_{\text{cyl}} = \frac{\left[\ln\frac{D_o}{D_i}\right]^4}{L_c^3(D_i^{-3/5}+D_o^{-3/5})^5} = \frac{\left[\ln\frac{0.09 \text{ m}}{0.05 \text{ m}}\right]^4}{(0.02 \text{ m})^3\left[(0.05 \text{ m})^{-7/5}+(0.09 \text{ m})^{-7/5}\right]^5} = 0.1303$$

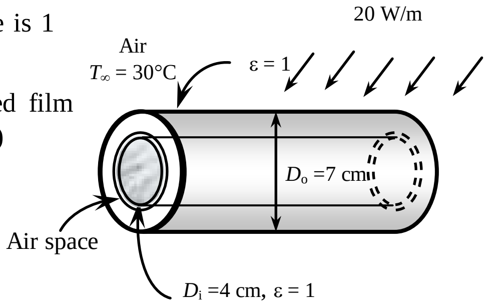
$$k_{\text{eff}} = 0.386k\left(\frac{\text{Pr}}{0.861+\text{Pr}}\right)^{1/4}(F_{\text{cyl}}\text{Ra})^{1/4}$$

$$= 0.386(0.02706 \text{ W/m.°C})\left(\frac{0.7239}{0.861+0.7239}\right)^{1/4}\left[(0.1303)(16{,}106)\right]^{1/4} = 0.05812 \text{ W/m.°C}$$

Then the heat loss from the collector per meter length of the tube becomes

$$\dot{Q} = \frac{2\pi k_{\text{eff}}}{\ln\left(\frac{D_o}{D_i}\right)}(T_i - T_o) = \frac{2\pi(0.05812 \text{ W/m.°C})}{\ln\left(\frac{0.09 \text{ m}}{0.05 \text{ m}}\right)}(60-32)°\text{C} = \mathbf{17.4 \text{ W}}$$

9-102 A solar collector consists of a horizontal tube enclosed in a concentric thin glass tube is considered. The pump circulating the water fails. The temperature of the aluminum tube when equilibrium is established is to be determined.



Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2$ = (33+30)/2 = 31.5°C are (Table A-15)

$$k = 0.02599 \text{ W/m.°C}$$
$$\upsilon = 1.622\times10^{-5} \text{ m}^2\text{/s}$$
$$\Pr = 0.7278$$
$$\beta = \frac{1}{T_f} = \frac{1}{(31.5+273)\text{K}} = 0.003284 \text{ K}^{-1}$$

Analysis This problem involves heat transfer from the aluminum tube to the glass cover, and from the outer surface of the glass cover to the surrounding ambient air. When steady operation is reached, these two heat transfers will be equal to the rate of heat gain. That is,

$$\dot{Q}_{tube-glass} = \dot{Q}_{glass-ambient} = \dot{Q}_{solar\ gain} = 20 \text{ W} \ \ \text{(per meter length)}$$

Now we assume the surface temperature of the glass cover to be 33°C. We will check this assumption later on, and repeat calculations with a better assumption, if necessary.

The characteristic length for the outer diameter of the glass cover $L_c = D_o$ =0.07 m. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)D_o^3}{\upsilon^2}\Pr = \frac{(9.81 \text{ m/s}^2)(0.003284 \text{ K}^{-1})(33-30 \text{ K})(0.07 \text{ m})^3}{(1.622\times10^{-5} \text{ m}^2\text{/s})^2}(0.7278) = 91{,}679$$

$$Nu = \left\{0.6 + \frac{0.387Ra^{1/6}}{\left[1+\left(0.559/\Pr\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6 + \frac{0.387(91{,}679)^{1/6}}{\left[1+\left(0.559/0.7278\right)^{9/16}\right]^{8/27}}\right\}^2 = 7.626$$

$$A_s = \pi D_o L = \pi(0.07 \text{ m})(1 \text{ m}) = 0.2199 \text{ m}^2$$

$$h = \frac{k}{D_o}Nu = \frac{0.02599 \text{ W/m.°C}}{0.07 \text{ m}}(7.626) = 2.832 \text{ W/m}^2\text{.°C}$$

and,

$$\dot{Q}_{conv} = hA_s(T_s - T_\infty) = (2.832 \text{ W/m}^2\text{.°C})(0.2199 \text{ m}^2)(T_{glass} - 30)\text{°C}$$

The radiation heat loss is

$$\dot{Q}_{rad} = \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4) = (1)(0.2199 \text{ m}^2)(5.67\times10^{-8} \text{ W/m}^2\text{.K}^4)\left[(T_{glass}+273 \text{ K})^4 - (20+273 \text{ K})^4\right]$$

The expression for the total rate of heat transfer is

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad}$$
$$20 \text{ W} = (2.832 \text{ W/m}^2\text{.°C})(0.2199 \text{ m}^2)(T_{glass} - 30)\text{°C}$$
$$+(1)(0.2199 \text{ m}^2)(5.67\times10^{-8} \text{ W/m}^2\text{.K}^4)\left[(T_{glass}+273 \text{ K})^4 - (20+273 \text{ K})^4\right]$$

Its solution is $T_{glass} = 33.34°\text{C}$, which is sufficiently close to the assumed value of 33°C.

Now we will calculate heat transfer through the air layer between aluminum tube and glass cover. We will assume the aluminum tube temperature to be 45°C and evaluate properties at the average temperature of

$(T_i+T_o)/2 = (45+33.34)/2 = 39.17°C$ are (Table A-15)

$$k = 0.02656 \text{ W/m.°C}$$
$$\upsilon = 1.694\times10^{-5} \text{ m}^2\text{/s}$$
$$\Pr = 0.7257$$
$$\beta = \frac{1}{T_f} = \frac{1}{(39.17+273)\text{K}} = 0.003203 \text{ K}^{-1}$$

The characteristic length in this case is the distance between the two cylinders,

$$L_c = (D_o - D_i)/2 = (7-4)/2 \text{ cm} = 1.5 \text{ cm}$$

Then,

$$Ra = \frac{g\beta(T_1-T_2)L_c^3}{\upsilon^2}\Pr = \frac{(9.81 \text{ m/s}^2)(0.003203 \text{ K}^{-1})(45-33.34 \text{ K})(0.015 \text{ m})^3}{(1.694\times10^{-5} \text{ m}^2\text{/s})^2}(0.7257) = 3125$$

The effective thermal conductivity is

$$F_{\text{cyl}} = \frac{\left[\ln\frac{D_o}{D_i}\right]^4}{L_c^3(D_i^{-3/5}+D_o^{-3/5})^5} = \frac{\left[\ln\frac{0.07 \text{ m}}{0.04 \text{ m}}\right]^4}{(0.015 \text{ m})^3\left[(0.04 \text{ m})^{-7/5}+(0.07 \text{ m})^{-7/5}\right]^5} = 0.1254$$

$$k_{\text{eff}} = 0.386k\left(\frac{\Pr}{0.861+\Pr}\right)^{1/4}(F_{\text{cyl}}\text{Ra})^{1/4}$$
$$= 0.386(0.02656 \text{ W/m.°C})\left(\frac{0.7257}{0.861+0.7257}\right)^{1/4}\left[(0.1254)(3125)\right]^{1/4} = 0.03751 \text{ W/m.°C}$$

The heat transfer expression is

$$\dot{Q} = \frac{2\pi k_{\text{eff}}}{\ln\left(\frac{D_o}{D_i}\right)}(T_1-T_2) = \frac{2\pi(0.03751 \text{ W/m.°C})}{\ln\left(\frac{0.07 \text{ m}}{0.04 \text{ m}}\right)}(T_{tube}-33.34)\text{°C}$$

The radiation heat loss is

$$\dot{Q}_{rad} = \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4) = (1)(0.1684 \text{ m}^2)(5.67\times10^{-8} \text{ W/m}^2.\text{K}^4)\left[(T_{tube}+273 \text{ K})^4 - (33.34+273 \text{ K})^4\right]$$

The expression for the total rate of heat transfer is

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad}$$
$$20 \text{ W} = \frac{2\pi(0.03751 \text{ W/m.°C})}{\ln\left(\frac{0.07 \text{ m}}{0.04 \text{ m}}\right)}(T_{tube}-33.34)\text{°C}$$
$$+(1)(0.1684 \text{ m}^2)(5.67\times10^{-8} \text{ W/m}^2.\text{K}^4)\left[(T_{tube}+273 \text{ K})^4 - (33.34+273 \text{ K})^4\right]$$

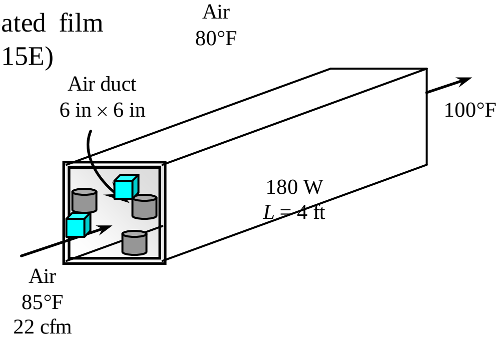
Its solution is $T_{tube} = \mathbf{45.9°\,C}$,

which is sufficiently close to the assumed value of 45°C. Therefore, there is no need to repeat the calculations.

9-103E The components of an electronic device located in a horizontal duct of rectangular cross section is cooled by forced air. The heat transfer from the outer surfaces of the duct by natural convection and the average temperature of the duct are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** Radiation effects are negligible. **5** The thermal resistance of the duct is negligible.

Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2$ = (120+80)/2 = 100°F are (Table A-15E)



$$k = 0.01529 \text{ Btu/h.ft.°F}$$
$$\upsilon = 0.1808\times10^{-3} \text{ ft}^2\text{/s}$$
$$\text{Pr} = 0.726$$
$$\beta = 1/T_f = 1/(100+460)\text{R} = 0.001786 \text{ R}^{-1}$$

Analysis (*a*) Using air properties at the average temperature of (85+100))/2 = 92.5°F and 1 atm for the forced air, the mass flow rate of air and the heat transfer rate by forced convection are determined to be

$$\dot{m} = \rho\dot{V} = (0.07186 \text{ lbm/ft}^3)(22 \text{ ft}^3\text{/min}) = 1.581 \text{ lbm/min}$$

$$\dot{Q}_{forced} = \dot{m}C_p(T_{out}-T_{in}) = (1.581\times60 \text{ lbm/h})(0.2405 \text{ Btu/lbm.°F})(100-85)\text{°F} = 342.1 \text{ Btu/h}$$

Noting that radiation heat transfer is negligible, the rest of the 180 W heat generated must be dissipated by natural convection,

$$\dot{Q}_{natural} = \dot{Q}_{total} - \dot{Q}_{forced} = (180\times3.412) - 342.1 = \mathbf{272\ Btu/h}$$

(*b*) We start the calculations by "guessing" the surface temperature to be 120°F for the evaluation of the properties and *h*. We will check the accuracy of this guess later and repeat the calculations if necessary.

Horizontal top surface: The characteristic length is $L_c = \dfrac{A_s}{P} = \dfrac{(4\text{ ft})(6/12\text{ ft})}{2(4\text{ ft}+6/12\text{ ft})} = 0.2222\text{ ft}$. Then,

$$Ra = \frac{g\beta(T_s-T_\infty)L_c^3}{\upsilon^2}\text{Pr} = \frac{(32.2\text{ ft/s}^2)(0.001786\text{ R}^{-1})(120-80\text{ R})(0.2222\text{ ft})^3}{(0.1808\times10^{-3}\text{ ft}^2\text{/s})^2}(0.726) = 5.604\times10^5$$

$$Nu = 0.54Ra^{1/4} = 0.54(5.604\times10^5)^{1/4} = 14.77$$

$$h_{top} = \frac{k}{L_c}Nu = \frac{0.01529\text{ Btu/h.ft.°F}}{0.2222\text{ ft}}(14.77) = 1.016\text{ Btu/h.ft}^2\text{.°F}$$

$$A_{top} = (4\text{ ft})(6/12\text{ ft}) = 2\text{ ft}^2 = A_{bottom}$$

Horizontal bottom surface: The Nusselt number for this geometry and orientation can be determined from

$$Nu = 0.27Ra^{1/4} = 0.27(5.604\times10^5)^{1/4} = 7.387$$

$$h_{bottom} = \frac{k}{L_c}Nu = \frac{0.01529\text{ Btu/h.ft.°F}}{0.2222\text{ ft}}(7.387) = 0.5082\text{ Btu/h.ft}^2\text{.°F}$$

Vertical side surfaces: The characteristic length in this case is the height of the duct, $L_c = L$ = 6 in. Then,

$$Ra = \frac{g\beta(T_s-T_\infty)L^3}{\upsilon^2}\text{Pr} = \frac{(32.2\text{ ft/s}^2)(0.001786\text{ R}^{-1})(120-80\text{ R})(0.5\text{ ft})^3}{(0.1808\times10^{-3}\text{ ft}^2\text{/s})^2}(0.726) = 6.383\times10^6$$

$$Nu = \left\{ 0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1 + \left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}} \right\}^2 = \left\{ 0.825 + \frac{0.387(6.383\times10^6)^{1/6}}{\left[1 + \left(\frac{0.492}{0.726}\right)^{9/16}\right]^{8/27}} \right\}^2 = 27.57$$

$$h_{side} = \frac{k}{L}Nu = \frac{0.01529\ \text{Btu/h.ft.°F}}{0.5\ \text{ft}}(27.57) = 0.843\ \text{Btu/h.ft}^2\text{.°F}$$

$$A_{side} = 2(4\ \text{ft})(0.5\ \text{ft}) = 4\ \text{ft}^2$$

Then the total heat loss from the duct can be expressed as

$$\dot{Q}_{total} = \dot{Q}_{top} + \dot{Q}_{bottom} + \dot{Q}_{side} = [(hA)_{top} + (hA)_{bottom} + (hA)_{side}](T_s - T_\infty)$$

Substituting and solving for the surface temperature,

$$272\ \text{Btu/h} = [(1.016\times2 + 0.5082\times2 + 0.843\times4)\ \text{Btu/h.°F}](T_s - 80)\text{°F}$$

T_s = **122.4°F**

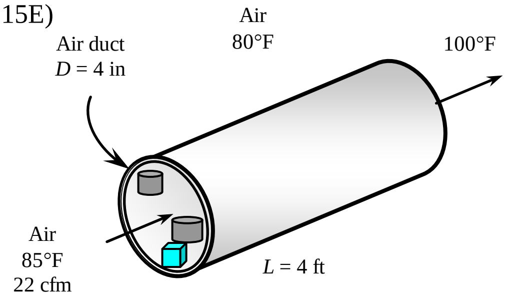
which is sufficiently close to the assumed value of 120°F used in the evaluation of properties and *h*. Therefore, there is no need to repeat the calculations.

9-104E The components of an electronic system located in a horizontal duct of circular cross section is cooled by forced air. The heat transfer from the outer surfaces of the duct by natural convection and the average temperature of the duct are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** Radiation effects are negligible. **5** The thermal resistance of the duct is negligible.

Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2$ = (150+80)/2 = 115°F are (Table A-15E)

$$k = 0.01564 \text{ Btu/h.ft.°F}$$
$$\upsilon = 0.1894\times10^{-3} \text{ ft}^2\text{/s}$$
$$\Pr = 0.7268$$
$$\beta = \frac{1}{T_f} = \frac{1}{(115+460)\text{ R}} = 0.001739 \text{ R}^{-1}$$



Analysis (a) Using air properties at the average temperature of (85+100))/2 = 92.5°F and 1 atm for the forced air, the mass flow rate of air and the heat transfer rate by forced convection are determined to be

$$\dot{m} = \rho\dot{V} = (0.07186 \text{ lbm/ft}^3)(22 \text{ ft}^3\text{/min}) = 1.581 \text{ lbm/min}$$

$$\dot{Q}_{forced} = \dot{m}C_p(T_{out}-T_{in}) = (1.581\times60 \text{ lbm/h})(0.2405 \text{ Btu/lbm.°F})(100-85)\text{°F} = 342.1 \text{ Btu/h}$$

Noting that radiation heat transfer is negligible, the rest of the 180 W heat generated must be dissipated by natural convection,

$$\dot{Q}_{natural} = \dot{Q}_{total} - \dot{Q}_{forced} = (180\times3.412) - 342.1 = \mathbf{272\ Btu/h}$$

(b) We start the calculations by “guessing” the surface temperature to be 150°F for the evaluation of the properties and *h*. We will check the accuracy of this guess later and repeat the calculations if necessary. The characteristic length in this case is the outer diameter of the duct, $L_c = D$ = 4 in. Then,

$$Ra = \frac{g\beta(T_1-T_2)D^3}{\upsilon^2}\Pr = \frac{(32.2 \text{ ft/s}^2)(0.001739 \text{ R}^{-1})(150-80 \text{ R})(4/12 \text{ ft})^3}{(0.1894\times10^{-3} \text{ ft}^2\text{/s})^2}(0.7268) = 2.930\times10^6$$

$$Nu = \left\{0.6+\frac{0.387Ra^{1/6}}{\left[1+(0.559/\Pr)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6+\frac{0.387(2.930\times10^6)^{1/6}}{\left[1+(0.559/0.7268)^{9/16}\right]^{8/27}}\right\}^2 = 19.79$$

$$h = \frac{k}{D}Nu = \frac{0.01564 \text{ Btu/h.ft.°F}}{4/12 \text{ ft}}(19.79) = 0.9287 \text{ Btu/h.ft}^2\text{.°F}$$
$$A_s = \pi DL = \pi(4/12 \text{ ft})(4 \text{ ft}) = 4.19 \text{ ft}^2$$

Then the surface temperature is determined to be

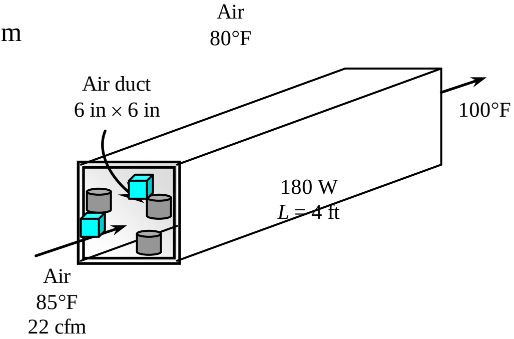
$$\dot{Q} = hA_s(T_s - T_\infty) \ \rightarrow\ T_s = T_\infty + \frac{\dot{Q}}{hA_s} = 80\text{°F} + \frac{272 \text{ Btu/h}}{(0.9287 \text{ Btu/h.ft}^2\text{.°F})(4.19 \text{ ft}^2)} = \mathbf{149.9°F}$$

which is practically equal to the assumed value of 150°F used in the evaluation of properties and *h*. Therefore, there is no need to repeat the calculations.

9-105E The components of an electronic system located in a horizontal duct of rectangular cross section is cooled by natural convection. The heat transfer from the outer surfaces of the duct by natural convection and the average temperature of the duct are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** Radiation effects are negligible. **5** The thermal resistance of the duct is negligible.

Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2 = (160+80)/2 = 120$°F are (Table A-15E)



$$k = 0.01576 \text{ Btu/h.ft.°F}$$
$$\upsilon = 0.1923\times10^{-3} \text{ ft}^2\text{/s}$$
$$\text{Pr} = 0.723$$
$$\beta = 1/T_f = 1/(120+460 \text{ R}) = 0.001724 \text{ R}^{-1}$$

Analysis (a) Noting that radiation heat transfer is negligible and no heat is removed by forced convection because of the failure of the fan, the entire 180 W heat generated must be dissipated by natural convection,

$$\dot{Q}_{natural} = \dot{Q}_{total} = \mathbf{180\ W}$$

(b) We start the calculations by "guessing" the surface temperature to be 160°F for the evaluation of the properties and h. We will check the accuracy of this guess later and repeat the calculations if necessary.

Horizontal top surface: The characteristic length is $L_c = \dfrac{A_s}{p} = \dfrac{(4 \text{ ft})(6/12 \text{ ft})}{2(4 \text{ ft}+6/12 \text{ ft})} = 0.2222 \text{ ft}$. Then,

$$Ra = \frac{g\beta(T_s-T_\infty)L_c^3}{\upsilon^2}\text{Pr} = \frac{(32.2 \text{ ft/s}^2)(0.001724 \text{ R}^{-1})(160-80 \text{ R})(0.2222 \text{ ft})^3}{(0.1923\times10^{-3} \text{ ft}^2\text{/s})^2}(0.723) = 9.534\times10^5$$

$$Nu = 0.54Ra^{1/4} = 0.54(9.534\times10^5)^{1/4} = 16.87$$

$$h_{top} = \frac{k}{L_c}Nu = \frac{0.01576 \text{ Btu/h.ft.°F}}{0.2222 \text{ ft}}(16.87) = 1.197 \text{ Btu/h.ft}^2\text{.°F}$$

$$A_{top} = (4 \text{ ft})(6/12 \text{ ft}) = 2 \text{ ft}^2 = A_{bottom}$$

Horizontal bottom surface: The Nusselt number for this geometry and orientation can be determined from

$$Nu = 0.27Ra^{1/4} = 0.27(9.534\times10^5)^{1/4} = 8.437$$

$$h_{bottom} = \frac{k}{L_c}Nu = \frac{0.01576 \text{ Btu/h.ft.°F}}{0.2222 \text{ ft}}(8.437) = 0.5983 \text{ Btu/h.ft}^2\text{.°F}$$

Vertical side surfaces: The characteristic length in this case is the height of the duct, $L_c = L = 6$ in. Then,

$$Ra = \frac{g\beta(T_s-T_\infty)L^3}{\upsilon^2}\text{Pr} = \frac{(32.2 \text{ ft/s}^2)(0.001724 \text{ R}^{-1})(160-80 \text{ R})(0.5 \text{ ft})^3}{(0.1923\times10^{-3} \text{ ft}^2\text{/s})^2}(0.723) = 1.086\times10^7$$

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(1.086\times10^7)^{1/6}}{\left[1+\left(\frac{0.492}{0.723}\right)^{9/16}\right]^{8/27}}\right\}^2 = 32.03$$

$$h_{side} = \frac{k}{L} Nu = \frac{0.01576\ \text{Btu/h.ft.°F}}{0.5\ \text{ft}}(32.03) = 1.009\ \text{Btu/h.ft}^2\text{.°F}$$

$$A_{side} = 2(4\ \text{ft})(0.5\ \text{ft}) = 4\ \text{ft}^2$$

Then the total heat loss from the duct can be expressed as

$$\dot{Q}_{total} = \dot{Q}_{top} + \dot{Q}_{bottom} + \dot{Q}_{side} = [(hA)_{top} + (hA)_{bottom} + (hA)_{side}](T_s - T_\infty)$$

Substituting and solving for the surface temperature,

$$180\ \text{W}\left(\frac{3.41214\ \text{Btu/h}}{1\ \text{W}}\right) = [(1.197 \times 2 + 0.5983 \times 2 + 1.009 \times 4)\ \text{Btu/h.°F}](T_s - 80)\text{°F}$$

T_s = **160.5°F**

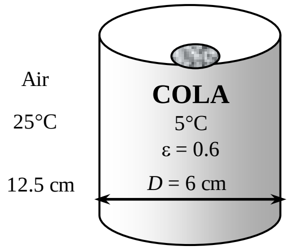
which is sufficiently close to the assumed value of 160°F used in the evaluation of properties and *h*. Therefore, there is no need to repeat the calculations.

9-106 A cold aluminum canned drink is exposed to ambient air. The time it will take for the average temperature to rise to a specified value is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** Any heat transfer from the bottom surface of the can is disregarded. **5** The thermal resistance of the can is negligible.

Properties The properties of air at 1 atm and the anticipated film temperature of $(T_s+T_\infty)/2$ = (6+25)/2 = 15.5°C are (Table A-15)

$$k = 0.0248\ \text{W/m.°C}$$
$$\upsilon = 1.475\times10^{-5}\ \text{m}^2/\text{s}$$
$$\text{Pr} = 0.7321$$
$$\beta = 1/T_f = 1/(15.5+273\ \text{K}) = 0.003466\ \text{K}^{-1}$$



Analysis We assume the surface temperature of aluminum can to be equal to the temperature of the drink in the can since the can is made of a very thin layer of aluminum. Noting that the temperature of the drink rises from 5°C to 7°C, we take the average surface temperature to be 6°C. The characteristic length in this case is the height of the box $L_c = L$ = 0.125 m. Then,

$$Ra = \frac{g\beta(T_\infty - T_s)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81\ \text{m/s}^2)(0.003466\ \text{K}^{-1})(25-6\ \text{K})(0.125\ \text{m})^3}{(1.475\times10^{-5}\ \text{m}^2/\text{s})^2}(0.7321) = 4.246\times10^6$$

At this point we should check if we can treat this aluminum can as a vertical plate. The criteria is

$$D \geq \frac{35L}{Gr^{1/4}} \longrightarrow \frac{35(12.5\ \text{cm})}{(4.246\times10^6\ /\ 0.7321)^{1/4}} = 9.92\ \text{cm}$$

which is not smaller than the diameter of the can (6 cm), but close to it. Therefore, we can still use vertical plate relation approximately (besides, we do not have another relation available). Then the Nusselt number becomes from

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(4.246\times10^6)^{1/6}}{\left[1+\left(\frac{0.492}{0.7321}\right)^{9/16}\right]^{8/27}}\right\}^2 = 23.81$$

$$h = \frac{k}{L}Nu = \frac{0.0248\ \text{W/m.°C}}{0.125\ \text{m}}(23.81) = 4.887\ \text{W/m}^2.\text{°C}$$

$$A_s = \pi DL + \frac{\pi D^2}{4} = \pi(0.06\ \text{m})(0.125\ \text{m}) + \frac{\pi(0.06\ \text{m})^2}{4} = 0.02639\ \text{m}^2$$

Note that we also include top surface area of the can to the total surface area, and assume the heat transfer coefficient for that area to be the same for simplicity (actually, it will be a little lower). Then heat transfer rate from outer surfaces of the can by natural convection becomes

$$\dot{Q} = hA_s(T_\infty - T_s) = (4.887\ \text{W/m}^2.\text{°C})(0.02639\ \text{m}^2)(25-6)\text{°C} = 2.45\ \text{W}$$

The radiation heat loss is

$$\dot{Q}_{rad} = \varepsilon A_s\sigma(T_{surr}{}^4 - T_s{}^4)$$
$$= (0.6)(0.02639\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)[(25+273\ \text{K})^4 - (6+273\ \text{K})^4] = 1.64\ \text{W}$$

and $\dot{Q}_{total} = 2.41 + 1.64 = 4.09\ \text{W}$

Using the properties of water for the cold drink at 6°C, the amount of heat transfer to the drink is determined from

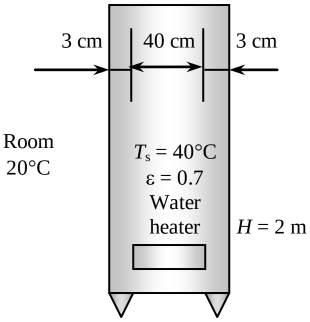
$$m = \rho V = \rho\frac{\pi D^2}{4}L = (1000\ \text{kg/m}^3)\frac{\pi(0.06\ \text{m})^2}{4}(0.125\ \text{m}) = 0.3534\ \text{kg}$$
$$Q = mC_p(T_2 - T_1) = (0.353\ \text{kg})(4197\ \text{J/kg.°C})(7-5)\text{°C} = 2967\ \text{J}$$

Then the time required for the temperature of the cold drink to rise to 7°C becomes

$$Q = \dot{Q}\Delta t \longrightarrow \Delta t = \frac{Q}{\dot{Q}} = \frac{2967\text{ J}}{4.09\text{ J/s}} = 725\text{ s} = \mathbf{12.1\,min}$$

9-107 An electric hot water heater is located in a small room. A hot water tank insulation kit is available for \$30. The payback period of this insulation to pay for itself from the energy it saves is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** Any heat transfer from the top and bottom surfaces of the tank is disregarded. **5** The thermal resistance of the metal sheet is negligible.



Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (40+20)/2 = 30°C$ are (Table A-15)

$$k = 0.02588 \text{ W/m.°C}$$
$$\upsilon = 1.608\times10^{-5} \text{ m}^2\text{/s}$$
$$\text{Pr} = 0.7282$$
$$\beta = \frac{1}{T_f} = \frac{1}{(30+273)\text{K}} = 0.0033 \text{ K}^{-1}$$

Analysis The characteristic length in this case is the height of the heater, $L_c = L = 2$ m. Then,

$$Ra = \frac{g\beta(T_\infty - T_s)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.0033 \text{ K}^{-1})(40-20 \text{ K})(2 \text{ m})^3}{(1.608\times10^{-5} \text{ m}^2\text{/s})^2}(0.7282) = 1.459\times10^{10}$$

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(1.459\times10^{10})^{1/6}}{\left[1+\left(\frac{0.492}{0.7282}\right)^{9/16}\right]^{8/27}}\right\}^2 = 285.4$$

$$h = \frac{k}{L}Nu = \frac{0.02588 \text{ W/m.°C}}{2 \text{ m}}(285.4) = 3.693 \text{ W/m}^2\text{.°C}$$
$$A_s = \pi DL = \pi(0.46 \text{ m})(2 \text{ m}) = 2.89 \text{ m}^2$$

and $\dot{Q} = hA_s(T_\infty - T_s) = (3.693 \text{ W/m}^2\text{.°C})(2.89 \text{ m}^2)(40-20)\text{°C} = 213.5 \text{ W}$

The radiation heat loss is

$$\dot{Q}_{rad} = \varepsilon A_s\sigma(T_{surr}{}^4 - T_s{}^4) = (0.7)(2.89 \text{ m}^2)(5.67\times10^{-8} \text{ W/m}^2\text{.K}^4)[(40+273 \text{ K})^4 - (20+273 \text{ K})^4] = 255.6 \text{ W}$$

and $\dot{Q}_{total} = 213.5 + 255.6 = 469 \text{ W}$

The reduction in heat loss after adding insulation is

$$\dot{Q} = (0.80)(469 \text{ W}) = 375.2 \text{ W}$$

The amount of heat and money saved per hour is

$$Q_{saved} = \dot{Q}_{saved}\Delta t = (0.3752 \text{ kW})(1 \text{ h}) = 0.3752 \text{ kWh}$$

$$\text{Money saved} = (0.3752 \text{ kWh})(\$0.08\text{/kWh}) = \$0.03002$$

Then it will take

$$\Delta t = \frac{\$30}{\$0.03002} = 999.4 \text{ h} = \mathbf{41.64 \text{ days}}$$

for the additional insulation to pay for itself from the energy it saves.

9-108 A hot part of the vertical front section of a natural gas furnace in a plant is considered. The rate of heat loss from this section and the annual cost of this heat loss are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** Any heat transfer from other surfaces of the tank is disregarded.

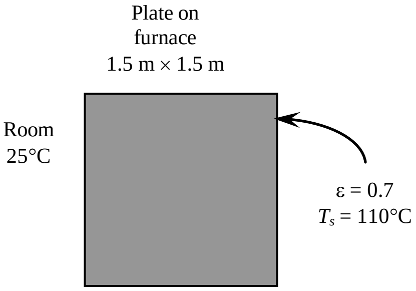
Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (110+25)/2 = 67.5$°C are (Table A-15)

$$k = 0.02863\ \text{W/m.°C}$$

$$\upsilon = 1.97\times10^{-5}\ \text{m}^2\text{/s}$$

$$\text{Pr} = 0.7184$$

$$\beta = \frac{1}{T_f} = \frac{1}{(67.5+273)\text{K}} = 0.002937\ \text{K}^{-1}$$



Analysis The characteristic length in this case is the height of that section of furnace, $L_c = L = 15$ m. Then,

$$Ra = \frac{g\beta(T_s - T_\infty)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81\,\text{m/s}^2)(0.002937\,\text{K}^{-1})(110-25\,\text{K})(1.5\,\text{m})^3}{(1.97\times10^{-5}\ \text{m}^2\text{/s})^2}(0.7184) = 1.530\times10^{10}$$

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(1.530\times10^{10})^{1/6}}{\left[1+\left(\frac{0.492}{0.7184}\right)^{9/16}\right]^{8/27}}\right\}^2 = 289.1$$

$$h = \frac{k}{L}Nu = \frac{0.02863\,\text{W/m.°C}}{1.5\,\text{m}}(289.1) = 5.518\ \text{W/m}^2\text{.°C}$$

$$A_s = (1\,\text{m})(1.5\,\text{m}) = 1.5\,\text{m}^2$$

and

$$\dot{Q} = hA_s(T_s - T_\infty) = (5.518\,\text{W/m}^2\text{.°C})(1.5\,\text{m}^2)(110-25)\text{°C} = 703.5\,\text{W}$$

The radiation heat loss is

$$\begin{aligned}\dot{Q}_{rad} &= \varepsilon A_s\sigma(T_{surr}{}^4 - T_s{}^4)\\ &= (0.7)(1.5\,\text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\text{.K}^4)[(110+273\,\text{K})^4 - (25+273\,\text{K})^4] = 812\ \text{W}\end{aligned}$$

$$\dot{Q}_{total} = 703.5 + 812 = \mathbf{1515\ \ W}$$

The amount and cost of natural gas used to overcome this heat loss per year is

$$Q_{gas} = \dot{Q}_{gas}\Delta t = \frac{\dot{Q}_{total}}{0.79}\Delta t = \frac{(1.5151\,\text{kJ/s})}{0.79}(310\ \text{days/yr}\times10\ \text{hr/day}\times3600\ \text{s/hr}) = 2.14\times10^7\ \text{kJ}$$

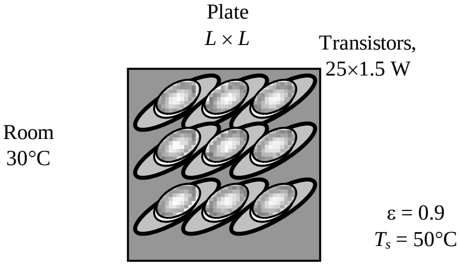
$$\text{Cost} = (2.14\times10^7\ /\ 105{,}500\ \text{therm})(\$0.75\text{/therm}) = \mathbf{\$152.2}$$

9-109 A group of 25 transistors are cooled by attaching them to a square aluminum plate and mounting the plate on the wall of a room. The required size of the plate to limit the surface temperature to 50°C is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** Any heat transfer from the back side of the plate is negligible.

Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (50+30)/2 = 40$°C are (Table A-15)

$$k = 0.02662 \text{ W/m.°C}$$
$$\upsilon = 1.702\times10^{-5} \text{ m}^2/\text{s}$$
$$\text{Pr} = 0.7255$$
$$\beta = \frac{1}{T_f} = \frac{1}{(40+273)\text{K}} = 0.003195 \text{ K}^{-1}$$



Analysis The Rayleigh number can be determined in terms of the characteristic length (length of the plate) to be

$$Ra = \frac{g\beta(T_\infty - T_s)L_c^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.003195 \text{ K}^{-1})(50-30 \text{ K})(L)^3}{(1.702\times10^{-5} \text{ m}^2/\text{s})^2}(0.7255) = 1.571\times10^9 L^3$$

The Nusselt number relation is

$$Nu = \left\{0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(1.571\times10^9 L^3)^{1/6}}{\left[1+\left(\frac{0.492}{0.7255}\right)^{9/16}\right]^{8/27}}\right\}^2$$

The heat transfer coefficient is

$$h = \frac{k}{L}Nu = \frac{0.02662 \text{ W/m.°C}}{L}Nu$$
$$A_s = L^2$$

Noting that both the surface and surrounding temperatures are known, the rate of convection and radiation heat transfer are expressed as

$$\dot{Q}_{\text{conv}} = hA_s(T_s - T_\infty) = \frac{0.02662 \text{ W/m.°C}}{L}NuL^2(50-30)\text{°C}$$
$$\dot{Q}_{\text{rad}} = \varepsilon A_s\sigma(T_s{}^4 - T_{sky}{}^4) = (0.9)L^2(5.67\times10^{-8} \text{ W/m}^2.\text{K}^4)[(50+273)^4-(30+273)^4]\text{K}^4 = 125.3L^2$$

The rate of total heat transfer is expressed as

$$\dot{Q}_{\text{total}} = \dot{Q}_{\text{conv}} + \dot{Q}_{\text{rad}}$$
$$25\times(1.5 \text{ W}) = \frac{0.02662 \text{ W/m.°C}}{L}NuL^2(50-30)\text{°C} + 125.3L^2$$

Substituting Nusselt number expression above into this equation and solving for L, the length of the plate is determined to be

L = **0.426 m**

9-110 A group of 25 transistors are cooled by attaching them to a square aluminum plate and positioning the plate horizontally in a room. The required size of the plate to limit the surface temperature to 50°C is to be determined for two cases.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** Any heat transfer from the back side of the plate is negligible.

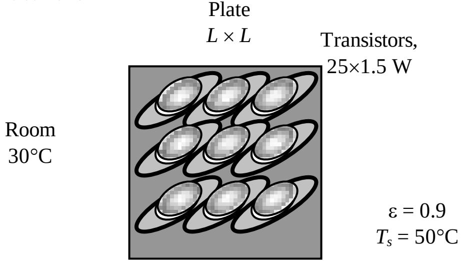
Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (50+30)/2 = 40$°C are (Table A-15)

$$k = 0.02662 \text{ W/m.°C}$$

$$\upsilon = 1.702\times10^{-5} \text{ m}^2\text{/s}$$

$$\text{Pr} = 0.7255$$

$$\beta = \frac{1}{T_f} = \frac{1}{(40+273)\text{K}} = 0.003195 \text{ K}^{-1}$$



Analysis The characteristic length and the Rayleigh number for the horizontal case are determined to be

$$L_c = \frac{A_s}{p} = \frac{L^2}{4L} = \frac{L}{4}$$

$$Ra = \frac{g\beta(T_\infty - T_s)L_c^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.003195 \text{ K}^{-1})(50-30 \text{ K})(L/4)^3}{(1.702\times10^{-5} \text{ m}^2\text{/s})^2}(0.7255) = 2.454\times10^7 L^3$$

Noting that both the surface and surrounding temperatures are known, the rate of radiation heat transfer is determined to be

$$\dot{Q}_{\text{rad}} = \varepsilon A_s\sigma(T_s{}^4 - T_{sky}{}^4) = (0.9)L^2(5.67\times10^{-8} \text{ W/m}^2\text{.K}^4)[(50+273)^4 - (30+273)^4]\text{K}^4 = 125.3L^2$$

(*a*) **Hot surface facing up:** We assume Ra < 10^7 and thus L <0.74 m so that we can determine the Nu number from Eq. 9-22. Then the Nusselt number and the convection heat transfer coefficient become

$$Nu = 0.54Ra^{1/4} = 0.54(2.454\times10^7 L^3)^{1/4} = 38.0L^{3/4}$$

Then,

$$h = \frac{k}{L}Nu = \frac{0.02662 \text{ W/m.°C}}{L/4}(38.0L^{3/4}) = 4.047L^{-1/4} \text{ W/m}^2\text{.°C}$$

$$A_s = L^2$$

The rate of convection heat transfer is

$$\dot{Q}_{\text{conv}} = hA_s(T_s - T_\infty) = (4.047L^{-1/4})L^2(50-30) = 80.94L^{7/8} \text{ W}$$

Then,

$$\dot{Q}_{\text{total}} = \dot{Q}_{\text{conv}} + \dot{Q}_{\text{rad}}$$

$$25\times(1.5 \text{ W}) = 80.94L^{7/4} + 125.3L^2 \text{ W}$$

Solving for L, the length of the plate is determined to be

L = **0.407 m**

Note that L < 0.75 m, and therefore the assumption of Ra < 10^7 is verified. That is,

(*b*) **Hot surface facing down:** The Nusselt number in this case is determined from

$$Nu = 0.27Ra^{1/4} = 0.27(2.454\times10^7 L^3)^{1/4} = 19.0L^{3/4}$$

Then,

$$h = \frac{k}{L_c}Nu = \frac{0.02662 \text{ W/m.°C}}{L/4}(19.0L^{3/4}) = 2.023L^{-1/4}$$

The rate of convection heat transfer is

$$\dot{Q}_{\text{conv}} = hA_s(T_s - T_\infty) = (2.023L^{-1/4})L^2(50-30) = 40.47L^{7/8} \quad \text{W}$$

Then,

$$\dot{Q}_{\text{total}} = \dot{Q}_{\text{conv}} + \dot{Q}_{\text{rad}}$$

$$25\times(1.5\ \text{W}) = 40.47L^{7/8} + 125.3L^2\ \text{W}$$

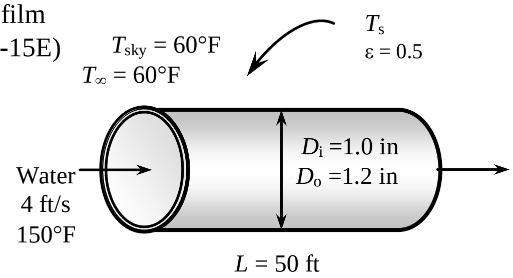
Solving for L, the length of the plate is determined to be

L = **0.464 m**

9-111E A hot water pipe passes through a basement. The temperature drop of water in the basement due to heat loss from the pipe is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the anticipated film temperature of (T_s+T_∞)/2 = (150+60)/2 = 105°F are (Table A-15E)



$$k = 0.01541\,\text{Btu/h.ft.°F}$$

$$\upsilon = 0.1837\times10^{-3}\ \text{ft}^2\text{/s}$$

$$\text{Pr} = 0.7253$$

$$\beta = \frac{1}{T_f} = \frac{1}{(105+460)\text{R}} = 0.00177\ \text{R}^{-1}$$

Analysis We expect the pipe temperature to be very close to the water temperature, and start the calculations by "guessing" the average outer surface temperature of the pipe to be 150°F for the evaluation of the properties and *h*. We will check the accuracy of this guess later and repeat the calculations if necessary. The characteristic length in this case is the outer diameter of the pipe, $L_c = D_o$ = 1.2 in. Then,

$$Ra = \frac{g\beta(T_\infty - T_s)D_o^3}{\upsilon^2}\text{Pr} = \frac{(32.2\ \text{ft/s}^2)(0.00177\ \text{R}^{-1})(150-60\ \text{R})(1.2/12\ \text{ft})^3}{(0.1837\times10^{-3}\ \text{ft}^2\text{/s})^2}(0.7253) = 1.102\times10^5$$

The natural convection Nusselt number can be determined from

$$Nu = \left\{0.6 + \frac{0.387Ra^{1/6}}{\left[1+\left(0.559/\text{Pr}\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6 + \frac{0.387(1.1023\times10^5)^{1/6}}{\left[1+\left(0.559/0.7253\right)^{9/16}\right]^{8/27}}\right\}^2 = 7.999$$

$$h_o = \frac{k}{D_o}Nu = \frac{0.01541\,\text{W/m.°C}}{(1.2/12)\,\text{ft}}(7.999) = 1.232\ \text{Btu/h.ft}^2\text{.°F}$$

$$A_i = \pi D_i L = \pi(1/12\ \text{ft})(50\ \text{ft}) = 13.09\ \text{ft}^2$$

$$A_o = \pi D_o L = \pi(1.2/12\ \text{ft})(50\ \text{ft}) = 15.708\ \text{ft}^2$$

Using the assumed value of glass temperature, the radiation heat transfer coefficient is determined to be

$$\begin{aligned} h_{rad} &= \varepsilon\sigma(T_s + T_{surr})(T_s{}^2 + T_{surr}{}^2) \\ &= (0.5)(0.1714\times10^{-8}\ \text{Btu/h.ft}^2\text{.R}^4)[(150+460)+(60+460)][(150+460)^2+(60+460)^2]R^3 \\ &= 0.6222\ \text{Btu/ft}^2\text{.R} \end{aligned}$$

Then the combined convection and radiation heat transfer coefficient outside becomes

$$h_{o,combined} = h_o + h_{rad} = 1.232 + 0.6222 = 1.854\ \text{Btu/ft}^2\text{.R}$$

and

$$\dot{Q} = \frac{T_{water} - T_\infty}{\dfrac{1}{h_i A_i} + \dfrac{\ln(D_o/D_i)}{4\pi kL} + \dfrac{1}{h_o A_o}} = \frac{150-60}{\dfrac{1}{(30)(13.09)} + \dfrac{\ln(1.2/1)}{4\pi(30)(50)} + \dfrac{1}{(1.854)(15.708)}} = 2440\ \text{Btu/h}$$

The mass flow rate of water

$$\dot{m} = \rho A_c V = (62.2\ \text{lbm/ft}^3)\left[\pi(1/12\ \text{ft})^2/4\right](4\ \text{ft/s}) = 1.357\ \text{lbm/s} = 4885\ \text{lbm/h}$$

Then the temperature drop of water as it flows through the pipe becomes

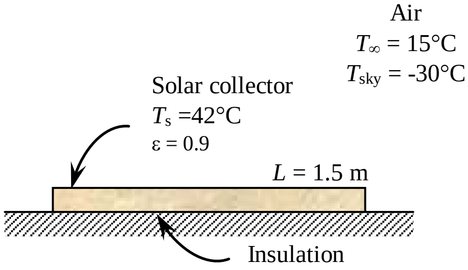
$$\dot{Q} = \dot{m}C_p\Delta T \ \rightarrow\ \Delta T = \frac{\dot{Q}}{\dot{m}C_p} = \frac{2440\ \text{Btu/h}}{(4885\ \text{lbm/h})(1.0\ \text{Btu/lbm.°F})} = \mathbf{0.50°F}$$

9-112 A flat-plate solar collector placed horizontally on the flat roof of a house is exposed to the calm ambient air. The rate of heat loss from the collector by natural convection and radiation are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (42+15)/2 = 28.5°\text{C}$ are (Table A-15)

$$k = 0.02577\ \text{W/m.°C}$$
$$\upsilon = 1.594\times10^{-5}\ \text{m}^2\text{/s}$$
$$\text{Pr} = 0.7286$$
$$\beta = \frac{1}{T_f} = \frac{1}{(28.5+273)\text{K}} = 0.003317\ \text{K}^{-1}$$



Analysis The characteristic length in this case is determined from

$$L_c = \frac{A_s}{p} = \frac{(1.5\ \text{m})(6\ \text{m})}{2(1.5\ \text{m}+6\ \text{m})} = 0.6\ \text{m}$$

Then,

$$Ra = \frac{g\beta(T_\infty - T_s)L_c^3}{\upsilon^2}\text{Pr} = \frac{(9.81\ \text{m/s}^2)(0.003317\ \text{K}^{-1})(42-15\ \text{K})(0.6\ \text{m})^3}{(1.594\times10^{-5}\ \text{m}^2\text{/s})^2}(0.7286) = 5.443\times10^8$$

$$Nu = 0.15Ra^{1/3} = 0.15(5.443\times10^8)^{1/3} = 122.5$$

$$h = \frac{k}{L_c}Nu = \frac{0.02577\ \text{W/m.°C}}{0.6\ \text{m}}(122.5) = 5.26\ \text{W/m}^2\text{.°C}$$

$$A_s = (1.5\ \text{m})(6\ \text{m}) = 9\ \text{m}^2$$

and

$$\dot{Q}_{conv} = hA_s(T_s - T_\infty) = (5.26\ \text{W/m}^2\text{.°C})(9\ \text{m}^2)(42-15)°\text{C} = \mathbf{1278\ W}$$

Heat transfer rate by radiation is

$$\begin{aligned}\dot{Q}_{rad} &= \varepsilon A_s\sigma(T_{surr}{}^4 - T_s{}^4)\\ &= (0.9)(9\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\text{.K}^4)[(42+273\ \text{K})^4 - (-30+273\ \text{K})^4] = \mathbf{2920\ W}\end{aligned}$$

9-113 A flat-plate solar collector tilted 40°C from the horizontal is exposed to the calm ambient air. The total rate of heat loss from the collector, the collector efficiency, and the temperature rise of water in the collector are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant properties. **3** The local atmospheric pressure is 1 atm. **4** There is no heat loss from the back surface of the absorber plate.

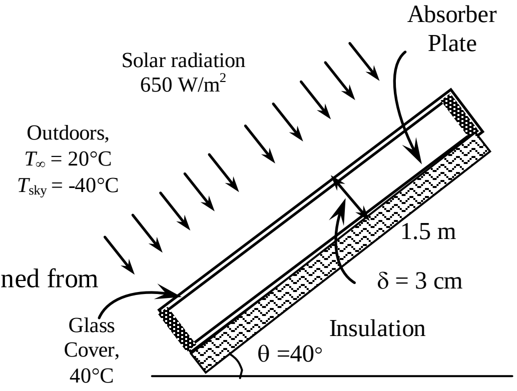
Properties The properties of air at 1 atm and the film temperature of $(T_s+T_\infty)/2$ = (40+20)/2 = 30°C are (Table A-15)

$$k = 0.02588\ \text{W/m.°C}$$

$$\upsilon = 1.608\times10^{-5}\ \text{m}^2\text{/s}$$

$$\text{Pr} = 0.7282$$

$$\beta = \frac{1}{T_f} = \frac{1}{(30+273)\text{K}} = 0.0033\ \text{K}^{-1}$$



Analysis (*a*) The characteristic length in this case is determined from

$$L_c = \frac{A_s}{p} = \frac{(1.5\ \text{m})(2\ \text{m})}{2(1.5\ \text{m}+2\ \text{m})} = 0.429\ \text{m}^2$$

Then,

$$Ra = \frac{g\beta(T_\infty - T_s)L_c^3}{\upsilon^2}\text{Pr} = \frac{(9.81\ \text{m/s}^2)(\cos 40°)(0.003311\ \text{K}^{-1})(40-20\ \text{K})(0.429\ \text{m})^3}{(1.608\times10^{-5}\ \text{m}^2\text{/s})^2}(0.7282) = 1.100\times10^8$$

$$Nu = 0.15Ra^{1/3} = 0.15(1.100\times10^8)^{1/3} = 71.87$$

$$h = \frac{k}{L_s}Nu = \frac{0.02588\ \text{W/m.°C}}{0.429\ \text{m}}(71.87) = 4.340\ \text{W/m}^2\text{.°C}$$

$$A_s = (1.5\ \text{m})(2\ \text{m}) = 3\ \text{m}^2$$

and

$$\dot{Q}_{conv} = hA_s(T_s - T_\infty) = (4.340\ \text{W/m}^2\text{.°C})(3\ \text{m}^2)(40-20)\text{°C} = 260.4\ \text{W}$$

Heat transfer rate by radiation is

$$\dot{Q}_{rad} = \varepsilon A_s\sigma(T_{surr}{}^4 - T_s{}^4)$$

$$= (0.9)(3\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\text{.K}^4)[(40+273\ \text{K})^4 - (-40+273\ \text{K})^4] = 1018\ \text{W}$$

and

$$\dot{Q}_{total} = 260.4 + 1018 = \mathbf{1279\ W}$$

(*b*) The solar energy incident on the collector is

$$\dot{Q}_{incident} = \alpha\dot{q}A_s = (0.88)(650\ \text{W/m}^2)(3\ \text{m}^2) = 1716\ \text{W}$$

Then the collector efficiency becomes

$$efficiency = \frac{\dot{Q}_{incident} - \dot{Q}_{lost}}{\dot{Q}_{incident}} = \frac{1716-1279}{1716} = 0.255 = \mathbf{25.5\%}$$

(*c*) The temperature rise of the water as it passes through the collector is

$$\dot{Q} = \dot{m}C_p\Delta T \rightarrow \Delta T = \frac{\dot{Q}}{\dot{m}C_p} = \frac{(1716-1279)\text{W}}{(1/60\ \text{kg/s})(4180\ \text{J/kg.°C})} = \mathbf{6.3\ °C}$$

Chapter 10

BOILING AND CONDENSATION

Boiling Heat Transfer

10-1C Boiling is the liquid-to-vapor phase change process that occurs at a solid-liquid interface when the surface is heated above the saturation temperature of the liquid. The formation and rise of the bubbles and the liquid entrainment coupled with the large amount of heat absorbed during liquid-vapor phase change at essentially constant temperature are responsible for the very high heat transfer coefficients associated with nucleate boiling.

10-2C Yes. Otherwise we can create energy by alternately vaporizing and condensing a substance.

10-3C Both boiling and evaporation are liquid-to-vapor phase change processes, but evaporation occurs at the *liquid-vapor interface* when the vapor pressure is less than the saturation pressure of the liquid at a given temperature, and it involves no bubble formation or bubble motion. Boiling, on the other hand, occurs at the *solid-liquid interface* when a liquid is brought into contact with a surface maintained at a temperature T_S sufficiently above the saturation temperature T_{sat} of the liquid.

10-4C Boiling is called *pool boiling* in the absence of bulk fluid flow, and *flow boiling* (or *forced convection boiling*) in the presence of it. In pool boiling, the fluid is stationary, and any motion of the fluid is due to natural convection currents and the motion of the bubbles due to the influence of buoyancy.

10-5C Boiling is said to be *subcooled* (or *local*) when the bulk of the liquid is subcooled (i.e., the temperature of the main body of the liquid is below the saturation temperature T_{sat}), and *saturated* (or *bulk*) when the bulk of the liquid is saturated (i.e., the temperature of all the liquid is equal to T_{sat}).

10-6C The boiling curve is given in Figure 10-6 in the text. In the *natural convection boiling* regime, the fluid motion is governed by natural convection currents, and heat transfer from the heating surface to the fluid is by natural convection. In the *nucleate boiling* regime, bubbles form at various preferential sites on the heating surface, and rise to the top. In the *transition boiling* regime, part of the surface is covered by a vapor film. In the *film boiling* regime, the heater surface is completely covered by a continuous stable vapor film, and heat transfer is by combined convection and radiation.

10-7C In the *film boiling* regime, the heater surface is completely covered by a continuous stable vapor film, and heat transfer is by combined convection and radiation. In the nucleate boiling regime, the heater surface is covered by the liquid. The boiling heat flux in the stable film boiling regime can be higher or lower than that in the nucleate boiling regime, as can be seen from the boiling curve.

10-8C The boiling curve is given in Figure 10-6 in the text. The burnout point in the curve is point C. The *burnout* during boiling is caused by the heater surface being blanketed by a continuous layer of vapor film at increased heat fluxes, and the resulting rise in heater surface temperature in order to maintain the same heat transfer rate across a low-conducting vapor film. Any attempt to increase the heat flux beyond $\dot{q}_{\max}$ will cause the operation point on the boiling curve to jump suddenly from point C to point E. However, the surface temperature that corresponds to point E is beyond the melting point of most heater materials, and burnout occurs. The burnout point is avoided in the design of boilers in order to avoid the disastrous explosions of the boilers.

10-9C Pool boiling heat transfer can be increased *permanently* by increasing the number of nucleation sites on the heater surface by *coating* the surface with a thin layer (much less than 1 mm) of very porous material, or by *forming cavities* on the surface mechanically to facilitate continuous vapor formation. Such surfaces are reported to enhance heat transfer in the nucleate boiling regime by a factor of up to 10, and the critical heat flux by a factor of 3. The use of finned surfaces is also known to enhance nucleate boiling heat transfer and the critical heat flux.

10-10C The different boiling regimes that occur in a vertical tube during flow boiling are forced convection of liquid, bubbly flow, slug flow, annular flow, transition flow, mist flow, and forced convection of vapor.

10-11 Water is boiled at 1 atm pressure and thus at a saturation (or boiling) temperature of T_{sat} = 100°C in a mechanically polished stainless steel pan whose inner surface temperature is maintained at T_s = 110° C. The rate of heat transfer to the water and the rate of evaporation of water are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Heat losses from the heater and the boiler are negligible.

Properties The properties of water at the saturation temperature of 100°C are (Tables 10-1 and A-9)

$\rho_l = 957.9 \text{ kg/m}^3$

$\rho_v = 0.60 \text{ kg/m}^3$

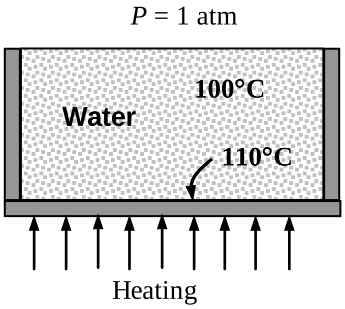
$\sigma = 0.0589 \text{ N/m}$

$\mathrm{Pr}_l = 1.75$

$h_{fg} = 2257 \times 10^3 \text{ J/kg}$

$\mu_l = 0.282 \times 10^{-3} \text{ kg}\cdot\text{m/s}$

$\mathrm{C}_{pl} = 4217 \text{ J/kg}\cdot{}^\circ\text{C}$



Also, $C_{sf} = 0.0130$ and n = 1.0 for the boiling of water on a mechanically polished stainless steel surface (Table 10-3). Note that we expressed the properties in units specified under Eq. 10-2 in connection with their definitions in order to avoid unit manipulations.

Analysis The excess temperature in this case is $\Delta T = T_s - T_{\mathrm{sat}} = 110 - 100 = 10^\circ\mathrm{C}$ which is relatively low (less than 30°C). Therefore, nucleate boiling will occur. The heat flux in this case can be determined from Rohsenow relation to be

$$\dot{q}_{\text{nucleate}} = \mu_l h_{fg}\left[\frac{g(\rho_l - \rho_v)}{\sigma}\right]^{1/2}\left(\frac{C_{p,l}(T_s - T_{\mathrm{sat}})}{C_{sf} h_{fg}\,\mathrm{Pr}_l^n}\right)^3$$

$$= (0.282\times10^{-3})(2257\times10^3)\left[\frac{9.8(957.9 - 0.60)}{0.0589}\right]^{1/2}\left(\frac{4217(110-100)}{0.0130(2257\times10^3)1.75}\right)^3$$

$$= 140{,}700 \text{ W/m}^2$$

The surface area of the bottom of the pan is

$$A_s = \pi D^2/4 = \pi(0.25\text{ m})^2/4 = 0.04909\text{ m}^2$$

Then the rate of heat transfer during nucleate boiling becomes

$$\dot{Q}_{\text{boiling}} = A_s \dot{q}_{\text{nucleate}} = (0.04909\text{ m}^2)(140{,}700\text{ W/m}^2) = \mathbf{6907\ W}$$

(*b*) The rate of evaporation of water is determined from

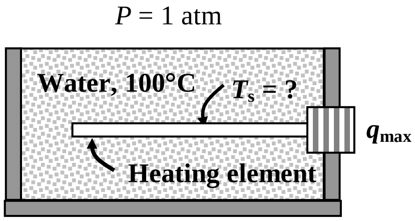
$$\dot{m}_{\text{evaporation}} = \frac{\dot{Q}_{\text{boiling}}}{h_{fg}} = \frac{6907\text{ J/s}}{2257\times10^3\text{ J/kg}} = \mathbf{3.06\times10^{-3}\ kg/s}$$

That is, water in the pan will boil at a rate of 3 grams per second.

10-12 Water is boiled at 1 atm pressure and thus at a saturation (or boiling) temperature of T_{sat} = 100°C by a mechanically polished stainless steel heating element. The maximum heat flux in the nucleate boiling regime and the surface temperature of the heater for that case are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Heat losses from the boiler are negligible.

Properties The properties of water at the saturation temperature of 100°C are (Tables 10-1 and A-9)



$$\rho_l = 957.9 \text{ kg/m}^3 \qquad h_{fg} = 2257\times10^3 \text{ J/kg}$$
$$\rho_v = 0.60 \text{ kg/m}^3 \qquad \mu_l = 0.282\times10^{-3} \text{ kg}\cdot\text{m/s}$$
$$\sigma = 0.0589 \text{ N/m} \qquad \text{C}_{pl} = 4217 \text{ J/kg}\cdot{}^\circ\text{C}$$
$$\text{Pr}_l = 1.75$$

Also, $C_{sf} = 0.0130$ and n = 1.0 for the boiling of water on a mechanically polished stainless steel surface (Table 10-3). Note that we expressed the properties in units specified under Eqs. 10-2 and 10-3 in connection with their definitions in order to avoid unit manipulations. For a large horizontal heating element, C_{cr} = 0.12 (Table 10-4). (It can be shown that L^* = 5.99 > 1.2 and thus the restriction in Table 10-4 is satisfied).

Analysis The maximum or critical heat flux is determined from

$$\begin{aligned}\dot{q}_{\max} &= C_{cr} h_{fg}[\sigma g \rho_v^2(\rho_l-\rho_v)]^{1/4} \\ &= 0.12(2257\times10^3)[0.0589\times9.8\times(0.6)^2(957.9-0.60)]^{1/4} \\ &= \mathbf{1{,}017{,}000\ W/m^2}\end{aligned}$$

The Rohsenow relation which gives the nucleate boiling heat flux for a specified surface temperature can also be used to determine the surface temperature when the heat flux is given. Substituting the maximum heat flux into the Rohsenow relation together with other properties gives

$$\dot{q}_{\text{nucleate}} = \mu_l h_{fg}\left[\frac{g(\rho_l-\rho_v)}{\sigma}\right]^{1/2}\left(\frac{C_{p,l}(T_s-T_{\text{sat}})}{C_{sf}h_{fg}\text{Pr}_l^n}\right)^3$$

$$1{,}017{,}000 = (0.282\times10^{-3})(2257\times10^3)\left[\frac{9.8(957.9-0.60)}{0.0589}\right]^{1/2}\left(\frac{4217(T_s-100)}{0.0130(2257\times10^3)1.75}\right)^3$$

It gives

$$T_s = \mathbf{119.3^\circ C}$$

Therefore, the temperature of the heater surface will be only 19.3°C above the boiling temperature of water when burnout occurs.

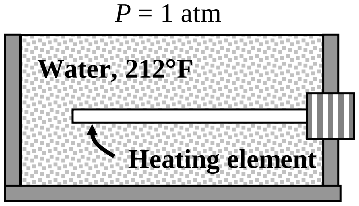
10-14E Water is boiled at 1 atm pressure and thus at a saturation (or boiling) temperature of T_{sat} = 212°F by a horizontal polished copper heating element whose surface temperature is maintained at T_s = 788°F. The rate of heat transfer to the water per unit length of the heater is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Heat losses from the boiler are negligible.

Properties The properties of water at the saturation temperature of 212°F are $\rho_l = 59.82\ \text{lbm/ft}^3$ and $h_{fg} = 970\ \text{Btu/lbm}$ (Table A-9E). The properties of the vapor at the film temperature of $T_f = (T_{sat} + T_s)/2 = (212 + 788)/2 = 500°\text{F}$ are (Table A-16E)

$$\begin{aligned}
\rho_v &= 0.02571\ \text{lbm/ft}^3\\
\mu_v &= 0.04564\ \text{Btu/lbm}\cdot\text{h}\\
C_{pv} &= 0.4707\ \text{Btu/lbm}\cdot°\text{F}\\
k_v &= 0.02267\ \text{Btu/h}\cdot\text{ft}\cdot°\text{F}
\end{aligned}$$



Also, g = 32.2 ft/s^2 = 32.2×(3600)^2 ft/h^2. Note that we expressed the properties in units that will cancel each other in boiling heat transfer relations. Also note that we used vapor properties at 1 atm pressure from Table A-16E instead of the properties of saturated vapor from Table A-9E since the latter are at the saturation pressure of 680 psia (46 atm).

Analysis The excess temperature in this case is $\Delta T = T_s - T_{sat} = 788 - 212 = 576°\text{F}$, which is much larger than 30°C or 54°F. Therefore, film boiling will occur. The film boiling heat flux in this case can be determined to be

$$\begin{aligned}
\dot{q}_{\text{film}} &= 0.62\left[\frac{g k_v^3 \rho_v(\rho_l - \rho_v)[h_{fg} + 0.4C_{pv}(T_s - T_{sat})]}{\mu_v D(T_s - T_{sat})}\right]^{1/4}(T_s - T_{sat})\\
&= 0.62\left[\frac{32.2(3600)^2(0.02267)^3(0.02571)(59.82 - 0.02571)[970 + 0.4\times 0.4707(788 - 212)]}{(0.04564)(0.5/12)(788 - 212)}\right]^{1/4}\times(788 - 212)\\
&= 18{,}600\ \text{Btu/h}\cdot\text{ft}^2
\end{aligned}$$

The radiation heat flux is determined from

$$\begin{aligned}
\dot{q}_{\text{rad}} &= \varepsilon\sigma(T_s^4 - T_{sat}^4)\\
&= (0.08)(0.1714\times 10^{-8}\ \text{Btu/h}\cdot\text{ft}^2\cdot\text{R}^4)\left[(788 + 460\ \text{R})^4 - (212 + 460\ \text{R})^4\right]\\
&= 305\ \text{Btu/h}\cdot\text{ft}^2
\end{aligned}$$

Note that heat transfer by radiation is very small in this case because of the low emissivity of the surface and the relatively low surface temperature of the heating element. Then the total heat flux becomes

$$\dot{q}_{\text{total}} = \dot{q}_{\text{film}} + \frac{3}{4}\dot{q}_{\text{rad}} = 18{,}600 + \frac{3}{4}\times 305 = 18{,}829\ \text{Btu/h}\cdot\text{ft}^2$$

Finally, the rate of heat transfer from the heating element to the water is determined by multiplying the heat flux by the heat transfer surface area,

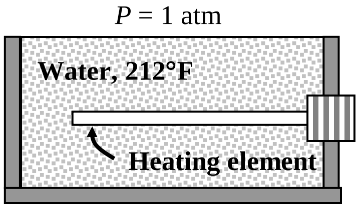
$$\begin{aligned}
\dot{Q}_{\text{total}} &= A_s\dot{q}_{\text{total}} = (\pi DL)\dot{q}_{\text{total}}\\
&= (\pi\times 0.5/12\ \text{ft}\times 1\ \text{ft})(18{,}829\ \text{Btu/h}\cdot\text{ft}^2)\\
&= \mathbf{2465\ Btu/h}
\end{aligned}$$

10-15E Water is boiled at 1 atm pressure and thus at a saturation (or boiling) temperature of T_{sat} = 212°F by a horizontal polished copper heating element whose surface temperature is maintained at T_s = 988°F. The rate of heat transfer to the water per unit length of the heater is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Heat losses from the boiler are negligible.

Properties The properties of water at the saturation temperature of 212°F are $\rho_l = 59.82\ \text{lbm/ft}^3$ and $h_{fg} = 970\ \text{Btu/lbm}$ (Table A-9E). The properties of the vapor at the film temperature of $T_f = (T_{\text{sat}} + T_s)/2 = (212+988)/2 = 600°\text{ F}$ are, by interpolation, (Table A-16E)

$$\begin{aligned}\rho_v &= 0.02395\ \text{lbm/ft}^3\\ \mu_v &= 0.05101\ \text{Btu/lbm}\cdot\text{h}\\ \text{C}_{pv} &= 0.4799\ \text{Btu/lbm}\cdot°\text{F}\\ k_v &= 0.02640\ \text{Btu/h}\cdot\text{ft}\cdot°\text{F}\end{aligned}$$



Also, g = 32.2 ft/s^2 = 32.2×(3600)^2 ft/h^2. Note that we expressed the properties in units that will cancel each other in boiling heat transfer relations. Also note that we used vapor properties at 1 atm pressure from Table A-16E instead of the properties of saturated vapor from Table A-9E since the latter are at the saturation pressure of 1541 psia (105 atm).

Analysis The excess temperature in this case is $\Delta T = T_s - T_{\text{sat}} = 988 - 212 = 776°\text{ F}$, which is much larger than 30°C or 54°F. Therefore, film boiling will occur. The film boiling heat flux in this case can be determined from

$$\begin{aligned}\dot{q}_{\text{film}} &= 0.62\left[\frac{gk_v^3\rho_v(\rho_l-\rho_v)[h_{fg}+0.4C_{pv}(T_s-T_{sat})]}{\mu_v D(T_s-T_{\text{sat}})}\right]^{1/4}(T_s-T_{\text{sat}})\\ &= 0.62\left[\frac{32.2(3600)^2(0.02640)^3(0.02395)(59.82-0.02395)[970+0.4\times0.4799(988-212)]}{(0.05101)(0.5/12)(988-212)}\right]^{1/4}\times(988-212)\\ &= 25{,}144\ \text{Btu/h}\cdot\text{ft}^2\end{aligned}$$

The radiation heat flux is determined from

$$\begin{aligned}\dot{q}_{\text{rad}} &= \varepsilon\sigma(T_s^4 - T_{\text{sat}}^4)\\ &= (0.08)(0.1714\times10^{-8}\ \text{Btu/h}\cdot\text{ft}^2\cdot\text{R}^4)\left[(988+460\ \text{R})^4-(212+460\ \text{R})^4\right]\\ &= 575\ \text{Btu/h}\cdot\text{ft}^2\end{aligned}$$

Note that heat transfer by radiation is very small in this case because of the low emissivity of the surface and the relatively low surface temperature of the heating element. Then the total heat flux becomes

$$\dot{q}_{\text{total}} = \dot{q}_{\text{film}} + \frac{3}{4}\dot{q}_{\text{rad}} = 25{,}144 + \frac{3}{4}\times575 = 25{,}576\ \text{Btu/h}\cdot\text{ft}^2$$

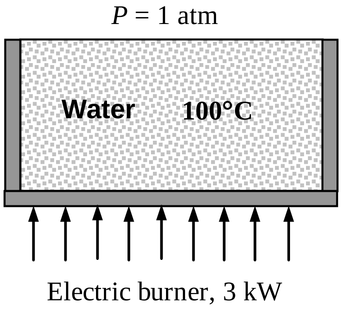
Finally, the rate of heat transfer from the heating element to the water is determined by multiplying the heat flux by the heat transfer surface area,

$$\begin{aligned}\dot{Q}_{\text{total}} &= A_s\dot{q}_{\text{total}} = (\pi DL)\dot{q}_{\text{total}}\\ &= (\pi\times0.5/12\ \text{ft}\times1\ \text{ft})(25{,}576\ \text{Btu/h}\cdot\text{ft}^2)\\ &= \mathbf{3348\ Btu/h}\end{aligned}$$

10-16 Water is boiled at sea level (1 atm pressure) and thus at a saturation (or boiling) temperature of T_{sat} = 100°C in a mechanically polished AISI 304 stainless steel pan placed on top of a 3-kW electric burner. Only 60% of the heat (1.8 kW) generated is transferred to the water. The inner surface temperature of the pan and the temperature difference across the bottom of the pan are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat losses from the boiler are negligible. **3** The boiling regime is nucleate boiling (this assumption will be checked later). **4** Heat transfer through the bottom of the pan is one-dimensional.

Properties The properties of water at the saturation temperature of 100°C are (Tables 10-1 and A-9)



$$\rho_l = 957.9 \text{ kg/m}^3 \qquad h_{fg} = 2257\times10^3 \text{ J/kg}$$
$$\rho_v = 0.60 \text{ kg/m}^3 \qquad \mu_l = 0.282\times10^{-3} \text{ kg}\cdot\text{m/s}$$
$$\sigma = 0.0589 \text{ N/m} \qquad C_{pl} = 4217 \text{ J/kg}\cdot{}^\circ\text{C}$$
$$\Pr_l = 1.75$$

Also, k_{steel} = 14.9 W/m·°C (Table A-3), $C_{sf} = 0.0130$ and n = 1.0 for the boiling of water on a mechanically polished stainless steel surface (Table 10-3). Note that we expressed the properties in units specified under Eq. 10-2 connection with their definitions in order to avoid unit manipulations.

Analysis The rate of heat transfer to the water and the heat flux are

$$\dot{Q} = 0.60\times 3\text{ kW} = 1.8\text{ kW} = 1800\text{ W}$$
$$A_s = \pi D^2/4 = \pi(0.30\text{ m})^2/4 = 0.07069\text{ m}^2$$
$$\dot{q} = \dot{Q}/A_s = (1800\text{ W})/(0.07069\text{ m}^2) = 25.46\text{ W/m}^2$$

Then temperature difference across the bottom of the pan is determined directly from the steady one-dimensional heat conduction relation to be

$$\dot{q} = k_{\text{steel}}\frac{\Delta T}{L} \rightarrow \Delta T = \frac{\dot{q}L}{k_{\text{steel}}} = \frac{(25{,}460\text{ W/m}^2)(0.006\text{ m})}{14.9\text{ W/m}\cdot{}^\circ\text{C}} = \mathbf{10.3^\circ C}$$

The Rohsenow relation which gives the nucleate boiling heat flux for a specified surface temperature can also be used to determine the surface temperature when the heat flux is given.

Assuming nucleate boiling, the temperature of the inner surface of the pan is determined from Rohsenow relation to be

$$\dot{q}_{\text{nucleate}} = \mu_l h_{fg}\left[\frac{g(\rho_l-\rho_v)}{\sigma}\right]^{1/2}\left(\frac{C_{p,l}(T_s-T_{\text{sat}})}{C_{sf}h_{fg}\Pr_l^n}\right)^3$$

$$25{,}460 = (0.282\times10^{-3})(2257\times10^3)\left[\frac{9.8(957.9-0.60)}{0.0589}\right]^{1/2}\left(\frac{4217(T_s-100)}{0.0130(2257\times10^3)1.75}\right)^3$$

It gives

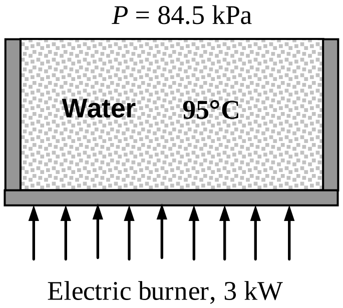
$$T_s = \mathbf{105.7^\circ C}$$

which is in the nucleate boiling range (5 to 30°C above surface temperature). Therefore, the nucleate boiling assumption is valid.

10-17 Water is boiled at 84.5 kPa pressure and thus at a saturation (or boiling) temperature of T_{sat} = 95°C in a mechanically polished AISI 304 stainless steel pan placed on top of a 3-kW electric burner. Only 60% of the heat (1.8 kW) generated is transferred to the water. The inner surface temperature of the pan and the temperature difference across the bottom of the pan are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat losses from the boiler are negligible. **3** The boiling regime is nucleate boiling (this assumption will be checked later). **4** Heat transfer through the bottom of the pan is one-dimensional.

Properties The properties of water at the saturation temperature of 95°C are (Tables 10-1 and A-9)



$$\rho_l = 961.5 \text{ kg/m}^3 \qquad h_{fg} = 2270\times10^3 \text{ J/kg}$$
$$\rho_v = 0.50 \text{ kg/m}^3 \qquad \mu_l = 0.297\times10^{-3} \text{ kg}\cdot\text{m/s}$$
$$\sigma = 0.0599 \text{ N/m} \qquad C_{pl} = 4212 \text{ J/kg}\cdot°\text{C}$$
$$\text{Pr}_l = 1.85$$

Also, k_{steel} = 14.9 W/m·°C (Table A-3), $C_{sf} = 0.0130$ and n = 1.0 for the boiling of water on a mechanically polished stainless steel surface (Table 10-3). Note that we expressed the properties in units specified under Eq. 10-2 in connection with their definitions in order to avoid unit manipulations.

Analysis The rate of heat transfer to the water and the heat flux are

$$\dot{Q} = 0.60\times 3\text{ kW} = 1.8\text{ kW} = 1800\text{ W}$$
$$A_s = \pi D^2/4 = \pi(0.30\text{ m})^2/4 = 0.07069\text{ m}^2$$
$$\dot{q} = \dot{Q}/A_s = (1800\text{ W})/(0.07069\text{ m}^2) = 25{,}460\text{ W/m}^2 = 25.46\text{ kW/m}^2$$

Then temperature difference across the bottom of the pan is determined directly from the steady one-dimensional heat conduction relation to be

$$\dot{q} = k_{\text{steel}}\frac{\Delta T}{L} \to \Delta T = \frac{\dot{q}L}{k_{\text{steel}}} = \frac{(25{,}460\text{ W/m}^2)(0.006\text{ m})}{14.9\text{ W/m}\cdot°\text{C}} = \mathbf{10.3°C}$$

The Rohsenow relation which gives the nucleate boiling heat flux for a specified surface temperature can also be used to determine the surface temperature when the heat flux is given.

Assuming nucleate boiling, the temperature of the inner surface of the pan is determined from Rohsenow relation to be

$$\dot{q}_{\text{nucleate}} = \mu_l h_{fg}\left[\frac{g(\rho_l-\rho_v)}{\sigma}\right]^{1/2}\left(\frac{C_{p,l}(T_s-T_{\text{sat}})}{C_{sf}h_{fg}\text{Pr}_l^n}\right)^3$$

$$25{,}460 = (0.297\times10^{-3})(2270\times10^3)\left[\frac{9.8(961.5-0.50)}{0.0599}\right]^{1/2}\left(\frac{4212(T_s-95)}{0.0130(2270\times10^3)1.85}\right)^3$$

It gives

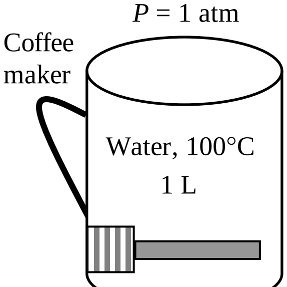
$$T_s = \mathbf{100.9°\,C}$$

which is in the nucleate boiling range (5 to 30°C above surface temperature). Therefore, the nucleate boiling assumption is valid.

10-18 Water is boiled at sea level (1 atm pressure) and thus at a saturation (or boiling) temperature of $T_{\rm sat}$ = 100°C by a stainless steel heating element. The surface temperature of the heating element and its power rating are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat losses from the coffee maker are negligible. **3** The boiling regime is nucleate boiling (this assumption will be checked later).

Properties The properties of water at the saturation temperature of 100°C are (Tables 10-1 and A-9)



$$\rho_l = 957.9 \text{ kg/m}^3 \qquad h_{fg} = 2257\times10^3 \text{ J/kg}$$
$$\rho_v = 0.60 \text{ kg/m}^3 \qquad \mu_l = 0.282\times10^{-3} \text{ kg}\cdot\text{m/s}$$
$$\sigma = 0.0589 \text{ N/m} \qquad C_{pl} = 4217 \text{ J/kg}\cdot{}^\circ\text{C}$$
$$\Pr_l = 1.75$$

Also, $C_{sf} = 0.0130$ and n = 1.0 for the boiling of water on a stainless steel surface (Table 10-3). Note that we expressed the properties in units specified under Eq. 10-2 connection with their definitions in order to avoid unit manipulations.

Analysis The density of water at room temperature is very nearly 1 kg/L, and thus the mass of 1 L water at 18°C is nearly 1 kg. The rate of energy transfer needed to evaporate half of this water in 25 min and the heat flux are

$$Q = \dot{Q}\Delta t = mh_{fg} \rightarrow \dot{Q} = \frac{mh_{fg}}{\Delta t} = \frac{(0.5\text{ kg})(2257\text{ kJ/kg})}{(25\times60\text{ s})} = 0.7523\text{ kW}$$
$$A_s = \pi DL = \pi(0.04\text{ m})(0.2\text{ m}) = 0.02513\text{ m}^2$$
$$\dot{q} = \dot{Q}/A_s = (0.7523\text{ kW})/(0.02513\text{ m}^2) = 29.94\text{ kW/m}^2 = 29{,}940\text{ W/m}^2$$

The Rohsenow relation which gives the nucleate boiling heat flux for a specified surface temperature can also be used to determine the surface temperature when the heat flux is given.

Assuming nucleate boiling, the temperature of the inner surface of the pan is determined from Rohsenow relation to be

$$\dot{q}_{\text{nucleate}} = \mu_l h_{fg}\left[\frac{g(\rho_l-\rho_v)}{\sigma}\right]^{1/2}\left(\frac{C_{p,l}(T_s-T_{\text{sat}})}{C_{sf}h_{fg}\Pr_l^n}\right)^3$$

$$29{,}940 = (0.282\times10^{-3})(2257\times10^3)\left[\frac{9.8(957.9-0.60)}{0.0589}\right]^{1/2}\left(\frac{4217(T_s-100)}{0.0130(2257\times10^3)1.75}\right)^3$$

It gives

$$T_s = \mathbf{106.0^\circ C}$$

which is in the nucleate boiling range (5 to 30°C above surface temperature). Therefore, the nucleate boiling assumption is valid.

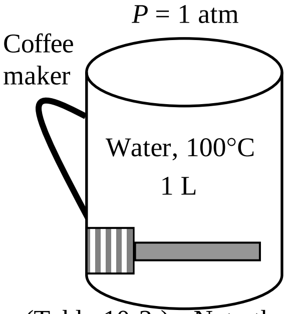
The specific heat of water at the average temperature of (18+100)/2 = 59°C is $C_{\rm p}$ = 4.184 kJ/kg·°C. Then the time it takes for the entire water to be heated from 18°C to 100°C is determined to be

$$Q = \dot{Q}\Delta t = mC_p\Delta T \rightarrow \Delta t = \frac{mC_p\Delta T}{\dot{Q}} = \frac{(1\text{ kg})(4.184\text{ kJ/kg}\cdot{}^\circ\text{C})(100-18)^\circ\text{C}}{0.7523\text{ kJ/s}} = 456\text{ s} = \mathbf{7.60\ min}$$

10-19 Water is boiled at sea level (1 atm pressure) and thus at a saturation (or boiling) temperature of T_{sat} = 100°C by a copper heating element. The surface temperature of the heating element and its power rating are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat losses from the coffee maker are negligible. **3** The boiling regime is nucleate boiling (this assumption will be checked later).

Properties The properties of water at the saturation temperature of 100°C are (Tables 10-1 and A-9)



$$\rho_l = 957.9 \text{ kg/m}^3 \qquad h_{fg} = 2257\times10^3 \text{ J/kg}$$
$$\rho_v = 0.60 \text{ kg/m}^3 \qquad \mu_l = 0.282\times10^{-3} \text{ kg}\cdot\text{m/s}$$
$$\sigma = 0.0589 \text{ N/m} \qquad C_{pl} = 4217 \text{ J/kg}\cdot{}^\circ\text{C}$$
$$\text{Pr}_l = 1.75$$

Also, $C_{sf} = 0.0130$ and n = 1.0 for the boiling of water on a copper surface (Table 10-3). Note that we expressed the properties in units specified under Eq. 10-2 connection with their definitions in order to avoid unit manipulations.

Analysis The density of water at room temperature is very nearly 1 kg/L, and thus the mass of 1 L water at 18°C is nearly 1 kg. The rate of energy transfer needed to evaporate half of this water in 25 min and the heat flux are

$$Q = \dot{Q}\Delta t = mh_{fg} \rightarrow \dot{Q} = \frac{mh_{fg}}{\Delta t} = \frac{(0.5\text{ kg})(2257\text{ kJ/kg})}{(25\times60\text{ s})} = 0.7523\text{ kW}$$
$$A_s = \pi DL = \pi(0.04\text{ m})(0.2\text{ m}) = 0.02513\text{ m}^2$$
$$\dot{q} = \dot{Q}/A_s = (0.7523\text{ kW})/(0.02513\text{ m}^2) = 29.94\text{ kW/m}^2 = 29{,}940\text{ W/m}^2$$

The Rohsenow relation which gives the nucleate boiling heat flux for a specified surface temperature can also be used to determine the surface temperature when the heat flux is given.

Assuming nucleate boiling, the temperature of the inner surface of the pan is determined from Rohsenow relation to be

$$\dot{q}_{\text{nucleate}} = \mu_l h_{fg}\left[\frac{g(\rho_l-\rho_v)}{\sigma}\right]^{1/2}\left(\frac{C_{p,l}(T_s-T_{\text{sat}})}{C_{sf}h_{fg}\text{Pr}_l^n}\right)^3$$

$$29{,}940 = (0.282\times10^{-3})(2257\times10^3)\left[\frac{9.8(957.9-0.60)}{0.0589}\right]^{1/2}\left(\frac{4217(T_s-100)}{0.0130(2257\times10^3)1.75}\right)^3$$

It gives

$$T_s = \mathbf{106.0^\circ C}$$

which is in the nucleate boiling range (5 to 30°C above surface temperature). Therefore, the nucleate boiling assumption is valid.

The specific heat of water at the average temperature of (18+100)/2 = 59°C is C_p = 4.184 kJ/kg·°C. Then the time it takes for the entire water to be heated from 18°C to 100°C is determined to be

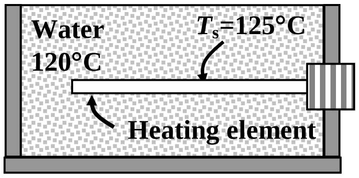
$$Q = \dot{Q}\Delta t = mC_p\Delta T \rightarrow \Delta t = \frac{mC_p\Delta T}{\dot{Q}} = \frac{(1\text{ kg})(4.184\text{ kJ/kg}\cdot{}^\circ\text{C})(100-18)^\circ\text{C}}{0.7523\text{ kJ/s}} = 456\text{ s} = \mathbf{7.60\ min}$$

10-20 Water is boiled at a saturation (or boiling) temperature of T_{sat} = 120°C by a brass heating element whose temperature is not to exceed T_s = 125°C. The highest rate of steam production is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat losses from the boiler are negligible. **3** The boiling regime is nucleate boiling since $\Delta T = T_s - T_{\text{sat}} = 125 - 120 = 5°\text{C}$ which is in the nucleate boiling range of 5 to 30°C for water.

Properties The properties of water at the saturation temperature of 120°C are (Tables 10-1 and A-9)

$$\rho_l = 943.4 \text{ kg/m}^3 \qquad h_{fg} = 2203 \times 10^3 \text{ J/kg}$$
$$\rho_v = 1.12 \text{ kg/m}^3 \qquad \mu_l = 0.232 \times 10^{-3} \text{ kg}\cdot\text{m/s}$$
$$\sigma = 0.0550 \text{ N/m} \qquad \text{C}_{pl} = 4244 \text{ J/kg}\cdot°\text{C}$$
$$\text{Pr}_l = 1.44$$



Also, $C_{sf} = 0.0060$ and n = 1.0 for the boiling of water on a brass surface (Table 10-3). Note that we expressed the properties in units specified under Eq. 10-2 in connection with their definitions in order to avoid unit manipulations.

Analysis Assuming nucleate boiling, the heat flux in this case can be determined from Rohsenow relation to be

$$\begin{aligned}\dot{q}_{\text{nucleate}} &= \mu_l h_{fg} \left[\frac{g(\rho_l - \rho_v)}{\sigma}\right]^{1/2} \left(\frac{C_{p,l}(T_s - T_{\text{sat}})}{C_{sf} h_{fg} \text{Pr}_l^n}\right)^3 \\ &= (0.232\times10^{-3})(2203\times10^3)\left[\frac{9.8(943.4-1.12)}{0.0550}\right]^{1/2}\left(\frac{4244(125-120)}{0.0060(2203\times10^3)1.44}\right)^3 \\ &= 290{,}190 \text{ W/m}^2\end{aligned}$$

The surface area of the heater is

$$A_s = \pi DL = \pi(0.02 \text{ m})(0.65 \text{ m}) = 0.04084 \text{ m}^2$$

Then the rate of heat transfer during nucleate boiling becomes

$$\dot{Q}_{\text{boiling}} = A_s \dot{q}_{\text{nucleate}} = (0.04084 \text{ m}^2)(290{,}190 \text{ W/m}^2) = 11{,}852 \text{ W}$$

(b) The rate of evaporation of water is determined from

$$\dot{m}_{\text{evaporation}} = \frac{\dot{Q}_{\text{boiling}}}{h_{fg}} = \frac{11{,}852 \text{ J/s}}{2203\times10^3 \text{ J/kg}}\left(\frac{3600 \text{ s}}{1 \text{ h}}\right) = \mathbf{19.4\ kg/h}$$

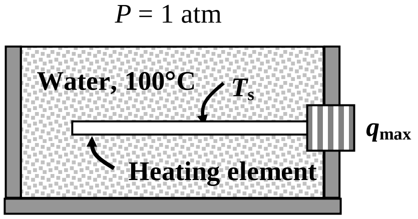
Therefore, steam can be produced at a rate of about 20 kg/h by this heater.

10-21 Water is boiled at 1 atm pressure and thus at a saturation (or boiling) temperature of T_{sat} = 100°C by a horizontal nickel plated copper heating element. The maximum (critical) heat flux and the temperature jump of the wire when the operating point jumps from nucleate boiling to film boiling regime are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Heat losses from the boiler are negligible.

Properties The properties of water at the saturation temperature of 100°C are (Tables 10-1 and A-9)

$$\rho_l = 957.9\ \text{kg/m}^3 \qquad h_{fg} = 2257\times10^3\ \text{J/kg}$$
$$\rho_v = 0.60\ \text{kg/m}^3 \qquad \mu_l = 0.282\times10^{-3}\ \text{kg}\cdot\text{m/s}$$
$$\sigma = 0.0589\ \text{N/m} \qquad \text{C}_{pl} = 4217\ \text{J/kg}\cdot{}^\circ\text{C}$$
$$\text{Pr}_l = 1.75$$



Also, $C_{sf} = 0.0060$ and n = 1.0 for the boiling of water on a nickel plated surface (Table 10-3). Note that we expressed the properties in units specified under Eqs. 10-2 and 10-3 in connection with their definitions in order to avoid unit manipulations. The vapor properties at the anticipated film temperature of $T_f = (T_s + T_{\text{sat}})/2$ of 1000°C (will be checked) (Table A-16)

$$\rho_v = 0.1725\ \text{kg/m}^3$$
$$C_{pv} = 2471\ \text{J/kg}\cdot{}^\circ\text{C}$$
$$k_v = 0.1362\ \text{W/m}\cdot{}^\circ\text{C}$$
$$\mu_v = 4.762\times10^{-5}\ \text{kg/m}\cdot\text{s}$$

Analysis (*a*) For a horizontal heating element, the coefficient C_{cr} is determined from Table 10-4 to be

$$L^* = L\left(\frac{g(\rho_l-\rho_v)}{\sigma}\right)^{1/2} = (0.0015)\left(\frac{9.8(957.9-0.60)}{0.0589}\right)^{1/2} = 0.60 < 1.2$$
$$C_{cr} = 0.12L^{*-0.25} = 0.12(0.60)^{-0.25} = 0.136$$

Then the maximum or critical heat flux is determined from

$$\begin{aligned}\dot{q}_{\max} &= C_{cr}h_{fg}[\sigma g\rho_v^2(\rho_l-\rho_v)]^{1/4}\\ &= 0.136(2257\times10^3)[0.0589\times9.8\times(0.6)^2(957.9-0.60)]^{1/4}\\ &= \mathbf{1{,}153{,}000\ W/m^2}\end{aligned}$$

The Rohsenow relation which gives the nucleate boiling heat flux for a specified surface temperature can also be used to determine the surface temperature when the heat flux is given. Substituting the maximum heat flux into the Rohsenow relation together with other properties gives

$$\dot{q}_{\text{nucleate}} = \mu_l h_{fg}\left[\frac{g(\rho_l-\rho_v)}{\sigma}\right]^{1/2}\left(\frac{C_{p,l}(T_s-T_{\text{sat}})}{C_{sf}h_{fg}\,\text{Pr}_l^n}\right)^3$$

$$1{,}153{,}000 = (0.282\times10^{-3})(2257\times10^3)\left[\frac{9.8(957.9\text{ - }0.60)}{0.0060}\right]^{1/2}\left(\frac{4217(T_s-100)}{0.0130(2257\times10^3)1.75}\right)^3$$

It gives

$$T_s = 109.3^\circ\text{C}$$

(*b*) Heat transfer in the film boiling region can be expressed as

$$\dot{q}_{\text{total}} = \dot{q}_{\text{film}} + \frac{3}{4}\dot{q}_{\text{rad}} = 0.62\left[\frac{gk_v^3\rho_v(\rho_l - \rho_v)[h_{fg} + 0.4C_{pv}(T_s - T_{sat})]}{\mu_v D(T_s - T_{\text{sat}})}\right]^{1/4}(T_s - T_{\text{sat}}) + \frac{3}{4}\varepsilon\sigma(T_s^4 - T_{\text{sat}}^4)$$

Substituting,

$$1{,}153{,}000 = 0.62\left[\frac{9.81(0.1362)^3(0.1723)(957.9 - 0.1725)[2257\times10^3 + 0.4\times2471(T_s - 100)]}{(4.762\times10^{-5})(0.003)(T_s - 100)}\right]^{1/4}\times(T_s - 100)$$
$$+ (0.5)(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)\left[(T_s + 273)^4 - (100 + 273)^4\right]$$

Solving for the surface temperature gives T_s = 1871°C. Therefore, the temperature jump of the wire when the operating point jumps from nucleate boiling to film boiling is

Temperature jump: $\Delta T = T_{\text{s, film}} - T_{s\text{,crit}} = 1871 - 109 = \mathbf{1762°C}$

Note that the film temperature is (1871+100)/2=985°C, which is close enough to the assumed value of 1000°C for the evaluation of vapor paroperties.

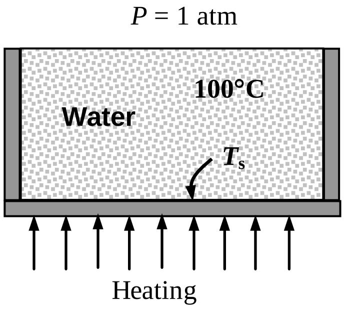
10-23 Water is boiled at sea level (1 atm pressure) and thus at a saturation (or boiling) temperature of T_{sat} = 100°C in a teflon-pitted stainless steel pan placed on an electric burner. The water level drops by 10 cm in 30 min during boiling. The inner surface temperature of the pan is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat losses from the pan are negligible. **3** The boiling regime is nucleate boiling (this assumption will be checked later).

Properties The properties of water at the saturation temperature of 100°C are (Tables 10-1 and A-9)



$\rho_l = 957.9 \text{ kg/m}^3$

$\rho_v = 0.60 \text{ kg/m}^3$

$\sigma = 0.0589 \text{ N/m}$

$\text{Pr}_l = 1.75$

$h_{fg} = 2257 \times 10^3 \text{ J/kg}$

$\mu_l = 0.282 \times 10^{-3} \text{ kg}\cdot\text{m/s}$

$C_{pl} = 4217 \text{ J/kg}\cdot°\text{C}$

Also, $C_{sf} = 0.0058$ and n = 1.0 for the boiling of water on a teflon-pitted stainless steel surface (Table 10-3). Note that we expressed the properties in units specified under Eq. 10-2 connection with their definitions in order to avoid unit manipulations.

Analysis The rate of heat transfer to the water and the heat flux are

$$\dot{m}_{\text{evap}} = \frac{m_{\text{evap}}}{\Delta t} = \frac{\rho \Delta V}{\Delta t} = \frac{(957.9 \text{ kg/m}^3)(\pi \times 0.2 \text{ m} \times 0.10 \text{ m})}{30 \times 60 \text{ s}} = 0.03344 \text{ kg/s}$$

$$\dot{Q} = \dot{m}_{\text{evap}} h_{fg} = (0.03344 \text{ kg/s})(2257 \text{ kJ/kg}) = 75.47 \text{ kW}$$

$$A_s = \pi D^2/4 = \pi(0.20 \text{ m})^2/4 = 0.03142 \text{ m}^2$$

$$\dot{q} = \dot{Q}/A_s = (75{,}470 \text{ W})/(0.03142 \text{ m}^2) = 2{,}402{,}000 \text{ W/m}^2$$

The Rohsenow relation which gives the nucleate boiling heat flux for a specified surface temperature can also be used to determine the surface temperature when the heat flux is given. Assuming nucleate boiling, the temperature of the inner surface of the pan is determined from Rohsenow relation to be

$$\dot{q}_{\text{nucleate}} = \mu_l h_{fg} \left[\frac{g(\rho_l - \rho_v)}{\sigma}\right]^{1/2} \left(\frac{C_{p,l}(T_s - T_{\text{sat}})}{C_{sf} h_{fg} \text{Pr}_l^n}\right)^3$$

$$2{,}402{,}000 = (0.282 \times 10^{-3})(2257 \times 10^3)\left[\frac{9.8(957.9 - 0.60)}{0.0589}\right]^{1/2}\left(\frac{4217(T_s - 100)}{0.0058(2257 \times 10^3)1.75}\right)^3$$

It gives

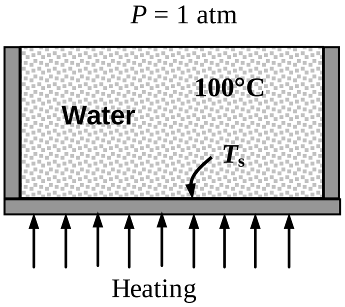
T_s = **111.5°C**

which is in the nucleate boiling range (5 to 30°C above surface temperature). Therefore, the nucleate boiling assumption is valid.

10-24 Water is boiled at sea level (1 atm pressure) and thus at a saturation (or boiling) temperature of T_{sat} = 100°C in a polished copper pan placed on an electric burner. The water level drops by 10 cm in 30 min during boiling. The inner surface temperature of the pan is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat losses from the pan are negligible. **3** The boiling regime is nucleate boiling (this assumption will be checked later).

Properties The properties of water at the saturation temperature of 100°C are (Tables 10-1 and A-9)



$$\rho_l = 957.9 \text{ kg/m}^3 \qquad h_{fg} = 2257\times10^3 \text{ J/kg}$$
$$\rho_v = 0.60 \text{ kg/m}^3 \qquad \mu_l = 0.282\times10^{-3} \text{ kg}\cdot\text{m/s}$$
$$\sigma = 0.0589 \text{ N/m} \qquad C_{pl} = 4217 \text{ J/kg}\cdot°\text{C}$$
$$\text{Pr}_l = 1.75$$

Also, $C_{sf} = 0.0130$ and n = 1.0 for the boiling of water on a copper surface (Table 10-3). Note that we expressed the properties in units specified under Eq. 10-2 connection with their definitions in order to avoid unit manipulations.

Analysis The rate of heat transfer to the water and the heat flux are

$$\dot{m}_{\text{evap}} = \frac{m_{\text{evap}}}{\Delta t} = \frac{\rho\Delta V}{\Delta t} = \frac{(957.9 \text{ kg/m}^3)(\pi\times0.2\text{ m}\times0.10\text{ m})}{30\times60\text{ s}} = 0.03344 \text{ kg/s}$$
$$\dot{Q} = \dot{m}_{\text{evap}} h_{fg} = (0.03344 \text{ kg/s})(2257 \text{ kJ/kg}) = 75.47 \text{ kW}$$
$$A_s = \pi D^2/4 = \pi(0.20\text{ m})^2/4 = 0.03142 \text{ m}^2$$
$$\dot{q} = \dot{Q}/A_s = (75{,}470 \text{ W})/(0.03142 \text{ m}^2) = 2{,}402{,}000 \text{ W/m}^2$$

The Rohsenow relation which gives the nucleate boiling heat flux for a specified surface temperature can also be used to determine the surface temperature when the heat flux is given. Assuming nucleate boiling, the temperature of the inner surface of the pan is determined from Rohsenow relation to be

$$\dot{q}_{\text{nucleate}} = \mu_l h_{fg}\left[\frac{g(\rho_l-\rho_v)}{\sigma}\right]^{1/2}\left(\frac{C_{p,l}(T_s-T_{\text{sat}})}{C_{sf}h_{fg}\text{Pr}_l^n}\right)^3$$

$$2{,}402{,}000 = (0.282\times10^{-3})(2257\times10^3)\left[\frac{9.8(957.9-0.60)}{0.0589}\right]^{1/2}\left(\frac{4217(T_s-100)}{0.0130(2257\times10^3)1.75}\right)^3$$

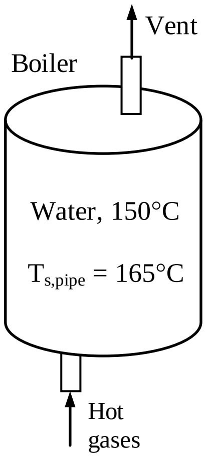
It gives

T_s = **125.7°C**

which is in the nucleate boiling range (5 to 30°C above surface temperature). Therefore, the nucleate boiling assumption is valid.

10-25 Water is boiled at a temperature of T_{sat} = 150°C by hot gases flowing through a mechanically polished stainless steel pipe submerged in water whose outer surface temperature is maintained at T_s = 165°C. The rate of heat transfer to the water, the rate of evaporation, the ratio of critical heat flux to current heat flux, and the pipe surface temperature at critical heat flux conditions are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat losses from the boiler are negligible. **3** The boiling regime is nucleate boiling since $\Delta T = T_s - T_{sat} = 165 - 150 = 15°\text{C}$ which is in the nucleate boiling range of 5 to 30°C for water.



Properties The properties of water at the saturation temperature of 150°C are (Tables 10-1 and A-9)

$$\rho_l = 916.6 \text{ kg/m}^3 \qquad h_{fg} = 2114 \times 10^3 \text{ J/kg}$$
$$\rho_v = 2.55 \text{ kg/m}^3 \qquad \mu_l = 0.183 \times 10^{-3} \text{ kg}\cdot\text{m/s}$$
$$\sigma = 0.0488 \text{ N/m} \qquad C_{pl} = 4311 \text{ J/kg}\cdot°\text{C}$$
$$\Pr_l = 1.16$$

Also, $C_{sf} = 0.0130$ and n = 1.0 for the boiling of water on a mechanically polished stainless steel surface (Table 10-3). Note that we expressed the properties in units specified under Eq. 10-2 in connection with their definitions in order to avoid unit manipulations.

Analysis (*a*) Assuming nucleate boiling, the heat flux can be determined from Rohsenow relation to be

$$\dot{q}_{\text{nucleate}} = \mu_l h_{fg} \left[\frac{g(\rho_l - \rho_v)}{\sigma}\right]^{1/2} \left(\frac{C_{p,l}(T_s - T_{\text{sat}})}{C_{sf} h_{fg} \Pr_l^n}\right)^3$$

$$= (0.183\times10^{-3})(2114\times10^3)\left[\frac{9.8(916.6-2.55)}{0.0488}\right]^{1/2}\left(\frac{4311(165-150)}{0.0130(2114\times10^3)1.16}\right)^3$$

$$= 1{,}383{,}000 \text{ W/m}^2$$

The heat transfer surface area is

$$A_s = \pi DL = \pi(0.05 \text{ m})(50 \text{ m}) = 7.854 \text{ m}^2$$

Then the rate of heat transfer during nucleate boiling becomes

$$\dot{Q}_{\text{boiling}} = A_s \dot{q}_{\text{nucleate}} = (7.854 \text{ m}^2)(1{,}383{,}000 \text{ W/m}^2) = \mathbf{10{,}865{,}000 \text{ W}}$$

(*b*) The rate of evaporation of water is determined from

$$\dot{m}_{\text{evaporation}} = \frac{\dot{Q}_{\text{boiling}}}{h_{fg}} = \frac{10{,}865 \text{ kJ/s}}{2114 \text{ kJ/kg}} = \mathbf{5.139 \text{ kg/s}}$$

(*c*) For a horizontal cylindrical heating element, the coefficient C_{cr} is determined from Table 10-4 to be

$$L^* = L\left(\frac{g(\rho_l - \rho_v)}{\sigma}\right)^{1/2} = (0.025)\left(\frac{9.8(916.6-2.55)}{0.0488}\right)^{1/2} = 10.7 > 0.12$$

$$C_{cr} = 0.12 \quad \text{(since } L^* > 1.2 \text{ and thus large cylinder)}$$

Then the maximum or critical heat flux is determined from

$$\begin{aligned}\dot{q}_{\max} &= C_{cr}h_{fg}[\sigma g\rho_v^2(\rho_l-\rho_v)]^{1/4}\\ &= 0.12(2114\times10^3)[0.0488\times9.8\times(2.55)^2(916.6-2.55)]^{1/4}\\ &= 1{,}852{,}000\ \text{W/m}^2\end{aligned}$$

Therefore, $\dfrac{\dot{q}_{\max}}{\dot{q}_{\text{current}}}=\dfrac{1{,}852{,}000}{1{,}383{,}000}=\mathbf{1.34}$

(*d*) The surface temperature of the pipe at the burnout point is determined from Rohsenow relation at the critical heat flux value to be

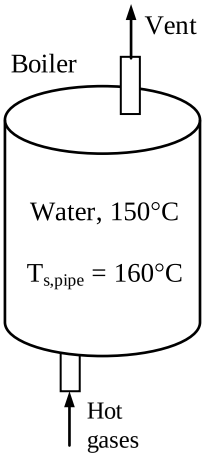
$$\dot{q}_{\text{nucleate,cr}}=\mu_l h_{fg}\left[\frac{g(\rho_l-\rho_v)}{\sigma}\right]^{1/2}\left(\frac{C_{p,l}(T_{s,cr}-T_{\text{sat}})}{C_{sf}h_{fg}\,\text{Pr}_l^n}\right)^3$$

$$1{,}852{,}000=(0.183\times10^{-3})(2114\times10^3)\left[\frac{9.8(916.6-2.55)}{0.0488}\right]^{1/2}\left(\frac{4311(T_{s,cr}-150)}{0.0130(2114\times10^3)1.16}\right)^3$$

$$T_{s,cr}=\mathbf{166.5^\circ C}$$

10-26 Water is boiled at a temperature of T_{sat} = 160°C by hot gases flowing through a mechanically polished stainless steel pipe submerged in water whose outer surface temperature is maintained at T_s = 165°C. The rate of heat transfer to the water, the rate of evaporation, the ratio of critical heat flux to current heat flux, and the pipe surface temperature at critical heat flux conditions are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat losses from the boiler are negligible. **3** The boiling regime is nucleate boiling since $\Delta T = T_s - T_{\text{sat}} = 165 - 160 = 5°\text{C}$ which is in the nucleate boiling range of 5 to 30°C for water.



Properties The properties of water at the saturation temperature of 160°C are (Tables 10-1 and A-9)

$$\rho_l = 907.4\ \text{kg/m}^3 \qquad h_{fg} = 2083\times10^3\ \text{J/kg}$$
$$\rho_v = 3.26\ \text{kg/m}^3 \qquad \mu_l = 0.170\times10^{-3}\ \text{kg}\cdot\text{m/s}$$
$$\sigma = 0.0466\ \text{N/m} \qquad C_{pl} = 4340\ \text{J/kg}\cdot°\text{C}$$
$$\text{Pr}_l = 1.09$$

Also, $C_{sf} = 0.0130$ and n = 1.0 for the boiling of water on a mechanically polished stainless steel surface (Table 10-3). Note that we expressed the properties in units specified under Eq. 10-2 in connection with their definitions in order to avoid unit manipulations.

Analysis (*a*) Assuming nucleate boiling, the heat flux can be determined from Rohsenow relation to be

$$\begin{aligned}\dot{q}_{\text{nucleate}} &= \mu_l h_{fg}\left[\frac{g(\rho_l-\rho_v)}{\sigma}\right]^{1/2}\left(\frac{C_{p,l}(T_s-T_{\text{sat}})}{C_{sf}h_{fg}\,\text{Pr}_l^n}\right)^3\\ &= (0.170\times10^{-3})(2083\times10^3)\left[\frac{9.8(907.4-3.26)}{0.0466}\right]^{1/2}\left(\frac{4340(165-160)}{0.0130(2083\times10^3)1.09}\right)^3\\ &= 61{,}359\ \text{W/m}^2\end{aligned}$$

The heat transfer surface area is

$$A_s = \pi DL = \pi(0.05\ \text{m})(50\ \text{m}) = 7.854\ \text{m}^2$$

Then the rate of heat transfer during nucleate boiling becomes

$$\dot{Q}_{\text{boiling}} = A_s\dot{q}_{\text{nucleate}} = (7.854\ \text{m}^2)(61{,}359\ \text{W/m}^2) = \mathbf{481{,}900\ W}$$

(*b*) The rate of evaporation of water is determined from

$$\dot{m}_{\text{evaporation}} = \frac{\dot{Q}_{\text{boiling}}}{h_{fg}} = \frac{481.9\ \text{kJ/s}}{2083\ \text{kJ/kg}} = \mathbf{0.231\ kg/s}$$

(*c*) For a horizontal cylindrical heating element, the coefficient C_{cr} is determined from Table 10-4 to be

$$L^* = L\left(\frac{g(\rho_l-\rho_v)}{\sigma}\right)^{1/2} = (0.025)\left(\frac{9.8(907.4-3.26)}{0.0466}\right)^{1/2} = 10.9 > 0.12$$
$$C_{cr} = 0.12 \quad (\text{since } L^* > 1.2 \text{ and thus large cylinder})$$

Then the maximum or critical heat flux is determined from

$$\begin{aligned}\dot{q}_{\max} &= C_{cr}h_{fg}[\sigma g\rho_v^2(\rho_l-\rho_v)]^{1/4}\\ &= 0.12(2083\times10^3)[0.0466\times9.8\times(3.26)^2(907.4-3.26)]^{1/4}\\ &= 2{,}034{,}000\ \text{W/m}^2\end{aligned}$$

Therefore, $$\frac{\dot{q}_{\text{max}}}{\dot{q}_{\text{current}}} = \frac{2{,}034{,}000}{61{,}359} = \mathbf{33.2}$$

(*d*) The surface temperature of the pipe at the burnout point is determined from Rohsenow relation at the critical heat flux value to be

$$\dot{q}_{\text{nucleate,cr}} = \mu_l h_{fg}\left[\frac{g(\rho_l-\rho_v)}{\sigma}\right]^{1/2}\left(\frac{C_{p,l}(T_{s,cr}-T_{\text{sat}})}{C_{sf}h_{fg}\,\text{Pr}_l^n}\right)^3$$

$$2{,}034{,}000 = (0.170\times10^{-3})(2083\times10^3)\left[\frac{9.8(907.4-3.26)}{0.0466}\right]^{1/2}\left(\frac{4340(T_{s,cr}-160)}{0.0130(2083\times10^3)1.09}\right)^3$$

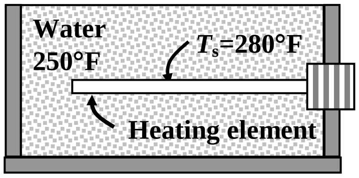
$$T_{s,cr} = \mathbf{176.1°C}$$

10-27E Water is boiled at a temperature of T_{sat} = 250°F by a nickel-plated heating element whose surface temperature is maintained at T_s = 280°F. The boiling heat transfer coefficient, the electric power consumed, and the rate of evaporation of water are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat losses from the boiler are negligible. **3** The boiling regime is nucleate boiling since $\Delta T = T_s - T_{\text{sat}} = 280 - 250 = 30°\text{ F}$ which is in the nucleate boiling range of 9 to 55°F for water.

Properties The properties of water at the saturation temperature of 250°F are (Tables 10-1 and A-9E)

$$\rho_l = 58.82 \text{ lbm / ft}^3 \qquad h_{fg} = 946 \text{ Btu / lbm}$$
$$\rho_v = 0.0723 \text{ lbm / ft}^3 \qquad \mu_l = 0.556 \text{ lbm / h} \cdot \text{ft}$$
$$\sigma = 0.003755 \text{ lbf / ft} = 0.1208 \text{ lbm / s}^2 \qquad \text{C}_{pl} = 1.015 \text{ Btu / lbm} \cdot °\text{F}$$
$$\text{Pr}_l = 1.43$$



Also, g = 32.2 ft/s^2 and $C_{sf} = 0.0060$ and n = 1.0 for the boiling of water on a nickel plated surface (Table 10-3). Note that we expressed the properties in units that will cancel each other in boiling heat transfer relations.

Analysis (*a*) Assuming nucleate boiling, the heat flux can be determined from Rohsenow relation to be

$$\begin{aligned}\dot{q}_{\text{nucleate}} &= \mu_l h_{fg} \left[\frac{g(\rho_l - \rho_v)}{\sigma}\right]^{1/2} \left(\frac{C_{p,l}(T_s - T_{\text{sat}})}{C_{sf} h_{fg} \text{ Pr}_l^n}\right)^3 \\ &= (0.556)(946)\left[\frac{32.2(58.82 - 0.0723)}{0.1208}\right]^{1/2}\left(\frac{1.015(280-250)}{0.0060(946)1.43}\right)^3 \\ &= 3{,}475{,}221 \text{ Btu/h} \cdot \text{ft}^2\end{aligned}$$

Then the convection heat transfer coefficient becomes

$$\dot{q} = h(T_s - T_{\text{sat}}) \ \rightarrow\ h = \frac{\dot{q}}{T_s - T_{\text{sat}}} = \frac{3{,}471{,}670 \text{ Btu / h} \cdot \text{ft}^2}{(280 - 250)°\text{ F}} = \mathbf{115{,}840\ Btu / h \cdot ft^2 \cdot °F}$$

(*b*) The electric power consumed is equal to the rate of heat transfer to the water, and is determined from

$$\begin{aligned}\dot{W}_e &= \dot{Q} = \dot{q}A_s = (\pi DL)\dot{q} = (\pi \times 0.5/12 \text{ ft} \times 2 \text{ ft})(3{,}475{,}221 \text{ Btu/h} \cdot \text{ft}^2) = 909{,}811 \text{ Btu/h} \\ &= \mathbf{266.6\ kW} \qquad (\text{since } 1 \text{ kW} = 3412 \text{ Btu/h})\end{aligned}$$

(*c*) Finally, the rate of evaporation of water is determined from

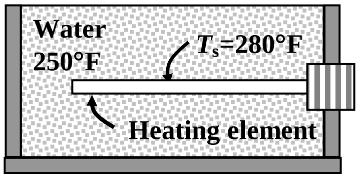
$$\dot{m}_{\text{evaporation}} = \frac{\dot{Q}_{\text{boiling}}}{h_{fg}} = \frac{909{,}811 \text{ Btu/h}}{946 \text{ Btu/lbm}} = \mathbf{961.7\ lbm/h}$$

10-28E Water is boiled at a temperature of T_{sat} = 250°F by a platinum-plated heating element whose surface temperature is maintained at T_s = 280°F. The boiling heat transfer coefficient, the electric power consumed, and the rate of evaporation of water are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat losses from the boiler are negligible. **3** The boiling regime is nucleate boiling since $\Delta T = T_s - T_{\text{sat}} = 280 - 250 = 30°\text{ F}$ which is in the nucleate boiling range of 9 to 55°F for water.

Properties The properties of water at the saturation temperature of 250°F are (Tables 10-1 and A-9E)

$$\rho_l = 58.82\text{ lbm/ft}^3 \qquad h_{fg} = 946\text{ Btu/lbm}$$
$$\rho_v = 0.0723\text{ lbm/ft}^3 \qquad \mu_l = 0.556\text{ lbm/h}\cdot\text{ft}$$
$$\sigma = 0.003755\text{ lbf/ft} = 0.1208\text{ lbm/s}^2 \qquad C_{pl} = 1.015\text{ Btu/lbm}\cdot°\text{F}$$
$$\Pr_l = 1.43$$



Also, g = 32.2 ft/s^2 and C_{sf} = 0.0130 and n = 1.0 for the boiling of water on a platinum plated surface (Table 10-3). Note that we expressed the properties in units that will cancel each other in boiling heat transfer relations.

Analysis (*a*) Assuming nucleate boiling, the heat flux can be determined from Rohsenow relation to be

$$\begin{aligned}\dot{q}_{\text{nucleate}} &= \mu_l h_{fg}\left[\frac{g(\rho_l-\rho_v)}{\sigma}\right]^{1/2}\left(\frac{C_{p,l}(T_s-T_{\text{sat}})}{C_{sf}h_{fg}\Pr_l^n}\right)^3\\ &= (0.556)(946)\left[\frac{32.2(58.82-0.0723)}{0.1208}\right]^{1/2}\left(\frac{1.015(280-250)}{0.0130(0.1208\times10^3)1.43}\right)^3\\ &= 341{,}670\text{ Btu/h}\cdot\text{ft}^2\end{aligned}$$

Then the convection heat transfer coefficient becomes

$$\dot{q} = h(T_s - T_{\text{sat}}) \;\to\; h = \frac{\dot{q}}{T_s - T_{\text{sat}}} = \frac{341{,}670\text{ Btu/h}\cdot\text{ft}^2}{(280-250)°\text{ F}} = \mathbf{11{,}390\ Btu/h\cdot ft^2\cdot°F}$$

(*b*) The electric power consumed is equal to the rate of heat transfer to the water, and is determined from

$$\begin{aligned}\dot{W}_e &= \dot{Q} = \dot{q}A_s = (\pi DL)\dot{q} = (\pi\times0.5/12\text{ ft}\times2\text{ ft})(341{,}670\text{ Btu/h}\cdot\text{ft}^2) = 89{,}450\text{ Btu/h}\\ &= \mathbf{26.2\ kW}\quad(\text{since }1\text{ kW} = 3412\text{ Btu/h})\end{aligned}$$

(*c*) Finally, the rate of evaporation of water is determined from

$$\dot{m}_{\text{evaporation}} = \frac{\dot{Q}_{\text{boiling}}}{h_{fg}} = \frac{89{,}450\text{ Btu/h}}{946\text{ Btu/lbm}} = \mathbf{94.6\ lbm/h}$$

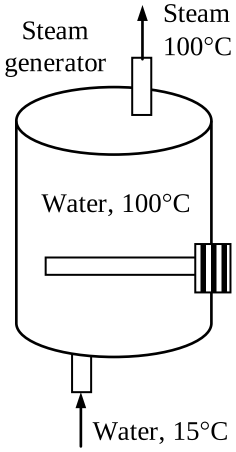
$\dot{m}_{evap}$ [lbm/h]
T_s [F]

10-30 Cold water enters a steam generator at 15°C and is boiled, and leaves as saturated vapor at T_{sat} = 100°C. The fraction of heat used to preheat the liquid water from 15°C to saturation temperature of 100°C is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Heat losses from the steam generator are negligible.

Properties The heat of vaporization of water at 100°C is h_{fg} = 2257 kJ/kg and the specific heat of liquid water at the average temperature of (15+100)/2 = 57.5°C is $C_{pl} = 4.184\ \text{kJ/kg}\cdot°\text{C}$ (Table A-9).

Analysis The heat of vaporization of water represents the amount of heat needed to vaporize a unit mass of liquid at a specified temperature. Using the average specific heat, the amount of heat needed to preheat a unit mass of water from 15°C to 100°C is determined to be



$$q_{\text{preheating}} = C_{pl}\Delta T = (4.184\ \text{kJ/kg}\cdot°\text{C})(100-15)°\text{C} = 355.6\ \text{kJ/kg}$$

and

$$q_{\text{total}} = q_{\text{boiling}} + q_{\text{preheating}} = 2257 + 355.6 = 2612.6\ \text{kJ/kg}$$

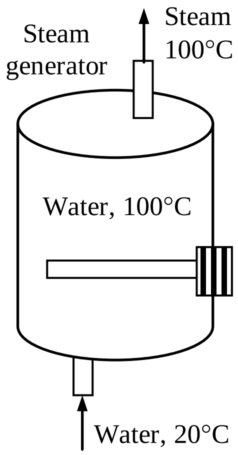
Therefore, the fraction of heat used to preheat the water is

$$\text{Fraction to preheat} = \frac{q_{\text{preheating}}}{q_{\text{total}}} = \frac{355.6}{2612.6} = \mathbf{0.136}\ \ (\text{or}\ \mathbf{13.6\%})$$

10-31 Cold water enters a steam generator at 20°C and is boiled, and leaves as saturated vapor at boiler pressure. The boiler pressure at which the amount of heat needed to preheat the water to saturation temperature is equal to the heat of vaporization is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Heat losses from the steam generator are negligible.

Properties The properties needed to solve this problem are the heat of vaporization h_{fg} and the specific heat of water C_p at specified temperatures, and they can be obtained from Table A-9.



Analysis The heat of vaporization of water represents the amount of heat needed to vaporize a unit mass of liquid at a specified temperature, and $C_p \Delta T$ represents the amount of heat needed to preheat a unit mass of water from 20°C to the saturation temperature. Therefore,

$$q_{\text{preheating}} = q_{\text{boiling}}$$
$$C_{p,ave}(T_{\text{sat}} - 20) = h_{fg@T_{\text{sat}}}$$

The solution of this problem requires choosing a boiling temperature, reading the heat of vaporization at that temperature, evaluating the specific heat at the average temperature, and substituting the values into the relation above to see if it is satisfied. By trial and error, the temperature that satisfies this condition is determined to be 315°C at which (Table A-9)

$$h_{fg@315°C} = 1281 \text{ kJ/kg} \quad \text{and} \quad T_{\text{ave}} = (20+315)/2 = 167.5°\text{C} \quad \rightarrow \quad C_{p,ave} = 4.37 \text{ kJ/kg}\cdot°\text{C}$$

Substituting,

$$C_{p,ave}(T_{\text{sat}} - 20) = (4.37 \text{ kJ/kg}\cdot°\text{C})(315-20)°\text{C} = 1289 \text{ kJ/kg}$$

which is practically identical to the heat of vaporization. Therefore,

$$P_{\text{boiler}} = P_{\text{sat}@T_{\text{sat}}} = \mathbf{10.6\ MPa}$$

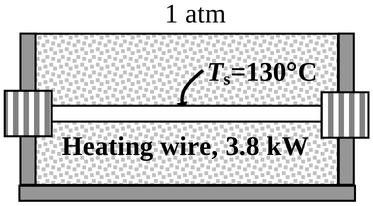
T_{cold} [C]

10-33 Boiling experiments are conducted by heating water at 1 atm pressure with an electric resistance wire, and measuring the power consumed by the wire as well as temperatures. The boiling heat transfer coefficient is to be determined.



Assumptions **1** Steady operating conditions exist. **2** Heat losses from the water are negligible.

Analysis The heat transfer area of the heater wire is

$$A_s = \pi DL = \pi(0.002\ \text{m})(0.50\ \text{m}) = 0.003142\ \text{m}^2$$

Noting that 3800 W of electric power is consumed when the heater surface temperature is 130°C, the boiling heat transfer coefficient is determined from Newton's law of cooling to be

$$\dot{Q} = hA_s(T_s - T_{\text{sat}}) \rightarrow h = \frac{\dot{Q}}{A_s(T_s - T_{\text{sat}})} = \frac{3800\ \text{W}}{(0.003142\ \text{m}^2)(130-100)°\text{C}} = \mathbf{40{,}320\ W/m^2\cdot°C}$$

Condensation Heat Transfer

10-34C Condensation is a vapor-to-liquid phase change process. It occurs when the temperature of a vapor is reduced *below* its saturation temperature T_{sat}. This is usually done by bringing the vapor into contact with a solid surface whose temperature T_S is *below* the saturation temperature T_{sat} of the vapor.

10-35C In *film condensation*, the condensate wets the surface and forms a liquid film on the surface which slides down under the influence of gravity. The thickness of the liquid film increases in the flow direction as more vapor condenses on the film. This is how condensation normally occurs in practice. In *dropwise condensation,* the condensed vapor forms droplets on the surface instead of a continuous film, and the surface is covered by countless droplets of varying diameters. Dropwise condensation is a much more effective mechanism of heat transfer.

10-36C In condensate flow, the wetted perimeter is defined as the length of the surface-condensate interface at a cross-section of condensate flow. It differs from the ordinary perimeter in that the latter refers to the entire circumference of the condensate at some cross-section.

10-37C The modified latent heat of vaporization h^*_{fg} is the amount of heat released as a unit mass of vapor condenses at a specified temperature, plus the amount of heat released as the condensate is cooled further to some average temperature between T_{sat} and T_s. It is defined as $h^*_{fg} = h_{fg} + 0.68C_{pl}(T_{sat} - T_s)$ where C_{pl} is the specific heat of the liquid at the average film temperature.

10-38C During film condensation on a vertical plate, heat flux at the top will be higher since the thickness of the film at the top, and thus its thermal resistance, is lower.

10-39C Setting the heat transfer coefficient relations for a vertical tube of height L and a horizontal tube of diameter D equal to each other yields $L = 2.77D$, which implies that for a tube whose length is 2.77 times its diameter, the average heat transfer coefficient for laminar film condensation will be the *same* whether the tube is positioned horizontally or vertically. For $L = 10D$, the heat transfer coefficient and thus the heat transfer rate will be higher in the horizontal position since $L > 2.77D$ in that case.

10-40C The condensation heat transfer coefficient for the tubes will be the highest for the case of horizontal side by side (case b) since (1) for long tubes, the horizontal position gives the highest heat transfer coefficients, and (2) for tubes in a vertical tier, the average thickness of the liquid film at the lower tubes is much larger as a result of condensate falling on top of them from the tubes directly above, and thus the average heat transfer coefficient at the lower tubes in such arrangements is smaller.

10-41C The presence of noncondensable gases in the vapor has a detrimental effect on condensation heat transfer. Even small amounts of a noncondensable gas in the vapor cause significant drops in heat transfer coefficient during condensation.

10-42 The hydraulic diameter D_h for all 4 cases are expressed in terms of the boundary layer thickness δ as follows:

(*a*) Vertical plate: $D_h = \frac{4A_c}{p} = \frac{4w\delta}{w} = 4\delta$

(*b*) Tilted plate: $D_h = \frac{4A_c}{p} = \frac{4w\delta}{w} = 4\delta$

(*c*)Vertical cylinder: $D_h = \frac{4A_c}{p} = \frac{4\pi D\delta}{\pi D} = 4\delta$

(*d*) Horizontal cylinder: $D_h = \frac{4A_c}{p} = \frac{4(2L\delta)}{2L} = 4\delta$

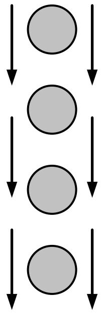
(*e*) Sphere: $D_h = \frac{4A_c}{p} = \frac{4\pi D\delta}{\pi D} = 4\delta$

Therefore, the Reynolds number for all 5 cases can be expressed as

$$\mathrm{Re} = \frac{4\dot{m}}{p\mu_l} = \frac{4A_c\rho_l V_l}{p\mu_l} = \frac{D_h\rho_l V_l}{\mu_l} = \frac{4\delta\rho_l V_l}{\mu_l}$$

10-43 There is film condensation on the outer surfaces of *N* horizontal tubes arranged in a vertical tier. The value of *N* for which the average heat transfer coefficient for the entire tier be equal to half of the value for a single horizontal tube is to be determined.

Assumptions Steady operating conditions exist.



Analysis The relation between the heat transfer coefficients for the two cases is given to be

$$h_{\text{horizontal, N tubes}} = \frac{h_{\text{horizontal, 1 tube}}}{N^{1/4}}$$

Therefore,

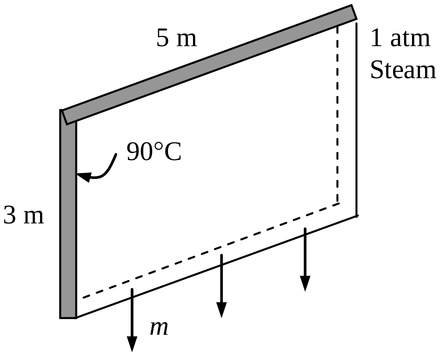
$$\frac{h_{\text{horizontal, N tubes}}}{h_{\text{horizontal,1 tube}}} = \frac{1}{2} = \frac{1}{N^{1/4}} \longrightarrow N = \mathbf{16}$$

10-44 Saturated steam at atmospheric pressure thus at a saturation temperature of T_{sat} = 100°C condenses on a vertical plate which is maintained at 90°C by circulating cooling water through the other side. The rate of heat transfer to the plate and the rate of condensation of steam are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The plate is isothermal. **3** The condensate flow is wavy-laminar over the entire plate (this assumption will be verified). **4** The density of vapor is much smaller than the density of liquid, $\rho_v << \rho_l$.

Properties The properties of water at the saturation temperature of 100°C are $h_{\text{fg}} = 2257\times10^3$ J/kg and ρ_v = 0.60 kg/m^3. The properties of liquid water at the film temperature of $T_f = (T_{\text{sat}} + T_s)/2 = (100 + 90)/2$ = 95°C are (Table A-9),

$$\rho_l = 961.5 \text{ kg/m}^3$$
$$\mu_l = 0.297\times10^{-3} \text{kg/m}\cdot\text{s}$$
$$\nu_l = \mu_l/\rho_l = 0.309\times10^{-6} \text{m}^2/\text{s}$$
$$C_{pl} = 4212 \text{ J/kg}\cdot°\text{C}$$
$$k_l = 0.677 \text{ W/m}\cdot°\text{C}$$



Analysis The modified latent heat of vaporization is

$$h^*_{fg} = h_{fg} + 0.68C_{pl}(T_{\text{sat}} - T_s)$$
$$= 2257\times10^3 \text{ J/kg} + 0.68\times4212 \text{ J/kg}\cdot°\text{C}(100-90)°\text{C} = 2{,}286\times10^3 \text{ J/kg}$$

Assuming wavy-laminar flow, the Reynolds number is determined from

$$\text{Re} = \text{Re}_{\text{vertical,wavy}} = \left[4.81 + \frac{3.70Lk_l(T_{\text{sat}}-T_s)}{\mu_l h^*_{fg}}\left(\frac{g}{\nu_l^2}\right)^{1/3}\right]^{0.820}$$

$$= \left[4.81 + \frac{3.70\times(3\text{ m})\times(0.677\text{ W/m}\cdot°\text{C})\times(100-90)°\text{C}}{(0.297\times10^{-3}\text{ kg/m}\cdot\text{s})(2286\times10^3\text{ J/kg})}\left(\frac{9.8\text{ m/s}^2}{(0.309\times10^{-6}\text{ m}^2/\text{s})^2}\right)^{1/3}\right]^{0.82} = 1112$$

which is between 30 and 1800, and thus our assumption of wavy laminar flow is verified. Then the condensation heat transfer coefficient is determined to be

$$h = h_{\text{vertical,wavy}} = \frac{\text{Re}\,k_l}{1.08\,\text{Re}^{1.22} - 5.2}\left(\frac{g}{\nu_l^2}\right)^{1/3}$$

$$= \frac{1112\times(0.677\text{ W/m}\cdot°\text{C})}{1.08(1112)^{1.22} - 5.2}\left(\frac{9.8\text{ m/s}^2}{(0.309\times10^{-6}\text{ m}^2/\text{s})^2}\right)^{1/3} = 6279\text{ W/m}^2\cdot°\text{C}$$

The heat transfer surface area of the plate is

$$A_s = W\times L = (3\text{ m})(5\text{ m}) = 15\text{ m}^2$$

Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA_s(T_{\text{sat}} - T_s) = (6279\text{ W/m}^2\cdot°\text{C})(15\text{ m}^2)(100-90)°\text{C} = \mathbf{941{,}850\text{ W}}$$

(*b*) The rate of condensation of steam is determined from

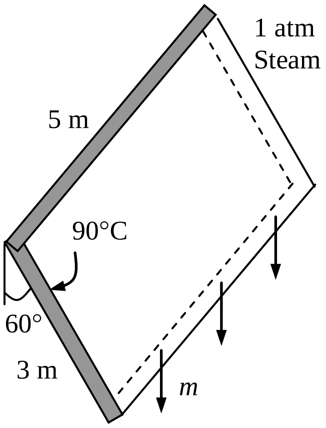
$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h^*_{fg}} = \frac{941{,}850\text{ J/s}}{2286\times10^3\text{ J/kg}} = \mathbf{0.412\text{ kg/s}}$$

10-45 Saturated steam at a saturation temperature of T_{sat} = 100°C condenses on a plate which is tilted 60° from the vertical and maintained at 90°C by circulating cooling water through the other side. The rate of heat transfer to the plate and the rate of condensation of the steam are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The plate is isothermal. **3** The condensate flow is wavy-laminar over the entire plate (this assumption will be verified). **4** The density of vapor is much smaller than the density of liquid, $\rho_v << \rho_l$.

Properties The properties of water at the saturation temperature of 100°C are $h_{fg} = 2257\times10^3$ J/kg and ρ_v = 0.60 kg/m^3. The properties of liquid water at the film temperature of $T_f = (T_{\text{sat}} + T_s)/2 = (100 + 90)/2 =$ 95°C are (Table A-9),

$$\rho_l = 961.5 \text{ kg/m}^3$$
$$\mu_l = 0.297\times10^{-3} \text{ kg/m}\cdot\text{s}$$
$$\nu_l = \mu_l/\rho_l = 0.309\times10^{-6} \text{ m}^2/\text{s}$$
$$C_{pl} = 4212 \text{ J/kg}\cdot°\text{C}$$
$$k_l = 0.677 \text{ W/m}\cdot°\text{C}$$



Analysis The modified latent heat of vaporization is

$$\begin{aligned} h^*_{fg} &= h_{fg} + 0.68C_{pl}(T_{\text{sat}} - T_s) \\ &= 2257\times10^3 \text{ J/kg} + 0.68\times4212 \text{ J/kg}\cdot°\text{C}(100-90)°\text{C} \\ &= 2{,}286\times10^3 \text{ J/kg} \end{aligned}$$

Assuming wavy-laminar flow, the Reynolds number is determined from the vertical plate relation by replacing g by $g\cos\theta$ where θ = 60° to be

$$\begin{aligned} \text{Re} = \text{Re}_{\text{tilted,wavy}} &= \left[4.81 + \frac{3.70Lk_l(T_{\text{sat}} - T_s)}{\mu_l h^*_{fg}}\left(\frac{g\cos 60}{\nu_l^2}\right)^{1/3}\right]^{0.820} \\ &= \left[4.81 + \frac{3.70\times(3\text{ m})\times(0.677 \text{ W/m}\cdot°\text{C})\times(100-90)°\text{C}}{(0.297\times10^{-3} \text{ kg/m}\cdot\text{s})(2286\times10^3 \text{ J/kg})}\left(\frac{(9.8 \text{ m/s}^2)\cos 60}{(0.309\times10^{-6} \text{ m}^2/\text{s})^2}\right)^{1/3}\right]^{0.82} = 950.5 \end{aligned}$$

which is between 30 and 1800, and thus our assumption of wavy laminar flow is verified. Then the condensation heat transfer coefficient is determined from

$$\begin{aligned} h = h_{\text{tilted,wavy}} &= \frac{\text{Re}\,k_l}{1.08\,\text{Re}^{1.22} - 5.2}\left(\frac{g\cos\theta}{\nu_l^2}\right)^{1/3} \\ &= \frac{950.5\times(0.677 \text{ W/m}\cdot°\text{C})}{1.08(950.5)^{1.22} - 5.2}\left(\frac{(9.8 \text{ m/s}^2)\cos 60}{(0.309\times10^{-6} \text{ m}^2/\text{s})^2}\right)^{1/3} = 5159 \text{ W/m}^2\cdot°\text{C} \end{aligned}$$

The heat transfer surface area of the plate is $A_s = W\times L = (3\text{ m})(5\text{ m}) = 15\text{ m}^2$.

Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA_s(T_{\text{sat}} - T_s) = (5159 \text{ W/m}^2\cdot°\text{C})(15\text{ m}^2)(100-90)°\text{C} = \mathbf{773{,}850\ W}$$

(*b*) The rate of condensation of steam is determined from

$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h^*_{fg}} = \frac{773{,}850 \text{ J/s}}{2286\times10^3 \text{ J/kg}} = \mathbf{0.339\ kg/s}$$

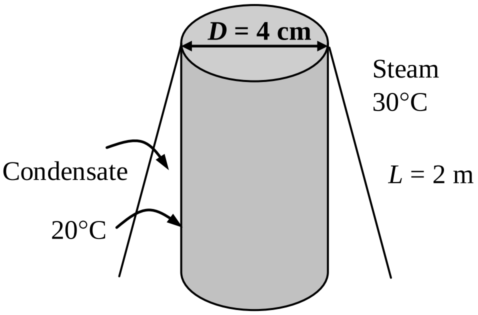
Discussion Using the heat transfer coefficient determined in the previous problem for the vertical plate, we could also determine the heat transfer coefficient from $h_{\text{inclined}} = h_{\text{vert}}(\cos\theta)^{1/4}$. It would give 5280 W/m^2·°C, which is 2.3% different than the value determined above.

10-46 Saturated steam condenses outside of vertical tube. The rate of heat transfer to the coolant, the rate of condensation and the thickness of the condensate layer at the bottom are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The tube is isothermal. **3** The tube can be treated as a vertical plate. **4** The condensate flow is wavy-laminar over the entire tube (this assumption will be verified). **5** Nusselt's analysis can be used to determine the thickness of the condensate film layer. **6** The density of vapor is much smaller than the density of liquid, $\rho_v << \rho_l$.

Properties The properties of water at the saturation temperature of 30°C are $h_{fg} = 2431\times10^3$ J/kg and $\rho_v = 0.03$ kg/m^3. The properties of liquid water at the film temperature of $T_f = (T_{\text{sat}} + T_s)/2 = (30 + 20)/2 =$ 25°C are (Table A-9),

$$\rho_l = 997.0 \text{ kg/m}^3$$
$$\mu_l = 1.002\times10^{-3} \text{kg/m}\cdot\text{s}$$
$$\nu_l = \mu_l/\rho_l = 1.005\times10^{-6} \text{m}^2/\text{s}$$
$$C_{pl} = 4180 \text{ J/kg}\cdot°\text{C}$$
$$k_l = 0.607 \text{ W/m}\cdot°\text{C}$$



Analysis (*a*)The modified latent heat of vaporization is

$$h^*_{fg} = h_{fg} + 0.68C_{pl}(T_{\text{sat}} - T_s)$$
$$= 2431\times10^3 \text{ J/kg} + 0.68\times4180 \text{ J/kg}\cdot°\text{C}(30-20)°\text{C} = 2459\times10^3 \text{ J/kg}$$

Assuming wavy-laminar flow, the Reynolds number is determined from

$$\text{Re} = \text{Re}_{\text{vertical,wavy}} = \left[4.81 + \frac{3.70Lk_l(T_{\text{sat}} - T_s)}{\mu_l h^*_{fg}}\left(\frac{g}{\nu_l^2}\right)^{1/3}\right]^{0.820}$$

$$= \left[4.81 + \frac{3.70\times(2\text{ m})\times(0.607 \text{ W/m}\cdot°\text{C})\times(30-20)°\text{C}}{(1.002\times10^{-3} \text{ kg/m}\cdot\text{s})(2459\times10^3 \text{ J/kg})}\left(\frac{9.8 \text{ m/s}^2}{(1.005\times10^{-6} \text{ m}^2/\text{s})^2}\right)^{1/3}\right]^{0.82} = 133.9$$

which is between 30 and 1800, and thus our assumption of wavy laminar flow is verified. Then the condensation heat transfer coefficient is determined to be

$$h = h_{\text{vertical,wavy}} = \frac{\text{Re}\,k_l}{1.08\,\text{Re}^{1.22} - 5.2}\left(\frac{g}{\nu_l^2}\right)^{1/3}$$

$$= \frac{133.9\times(0.607 \text{ W/m}\cdot°\text{C})}{1.08(133.9)^{1.22} - 5.2}\left(\frac{9.8 \text{ m/s}^2}{(1.005\times10^{-6} \text{ m}^2/\text{s})^2}\right)^{1/3} = 4132 \text{ W/m}^2\cdot°\text{C}$$

The heat transfer surface area of the tube is $A_s = \pi DL = \pi(0.04\text{ m})(2\text{ m}) = 0.2513\text{ m}^2$. Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA_s(T_{\text{sat}} - T_s) = (4132 \text{ W/m}^2\cdot°\text{C})(0.2513\text{ m}^2)(30-20)°\text{C} = \mathbf{10{,}385\ W}$$

(*b*) The rate of condensation of steam is determined from

$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h^*_{fg}} = \frac{10{,}385 \text{ J/s}}{2459\times10^3 \text{ J/kg}} = \mathbf{4.22\times10^{-3}\ kg/s}$$

(*c*) Combining equations $\delta_L = k_l/h_l$ and $h = (4/3)h_L$, the thickness of the liquid film at the bottom of the tube is determined to be

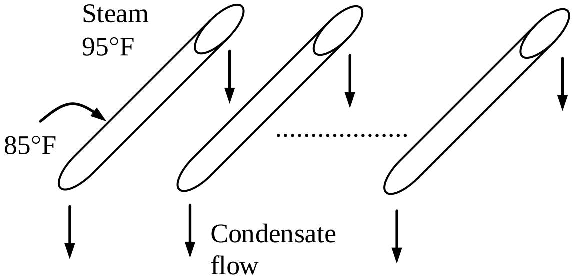
$$\delta_L = \frac{4k_l}{3h} = \frac{4(0.607 \text{ W/m}\cdot°\text{C})}{3(4132 \text{ W/m}^2\cdot°\text{C})} = 0.196\times10^{-3} = \mathbf{0.2\ mm}$$

10-47E Saturated steam at a saturation temperature of T_{sat} = 95°F condenses on the outer surfaces of horizontal pipes which are maintained at 85°F by circulating cooling water. The rate of heat transfer to the cooling water and the rate of condensation per unit length of a single horizontal pipe are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The pipe is isothermal. **3** There is no interference between the pipes (no drip of the condensate from one tube to another).

Properties The properties of water at the saturation temperature of 95°F are h_{fg} = 1040 Btu/lbm and ρ_v = 0.0025 lbm/ft^3. The properties of liquid water at the film temperature of $T_f = (T_{\text{sat}} + T_s)/2 = (95 + 85)/2$ = 90°F are (Table A-9E),

$$\rho_l = 62.12 \text{ lbm/ft}^3$$
$$\mu_l = 1.842 \text{ lbm/ft}\cdot\text{h}$$
$$\nu_l = \mu_l/\rho_l = 0.02965 \text{ ft}^2/\text{h}$$
$$C_{pl} = 0.999 \text{ Btu/lbm}\cdot°\text{F}$$
$$k_l = 0.358 \text{ Btu/h}\cdot\text{ft}\cdot°\text{F}$$



Analysis The modified latent heat of vaporization is

$$\begin{aligned} h^*_{fg} &= h_{fg} + 0.68C_{pl}(T_{\text{sat}} - T_s) \\ &= 1040 \text{ Btu/lbm} + 0.68 \times (0.999 \text{ Btu/lbm}\cdot°\text{F})(95-85)°\text{F} \\ &= 1047 \text{ Btu/lbm} \end{aligned}$$

Noting that we have condensation on a horizontal tube, the heat transfer coefficient is determined from

$$h = h_{\text{horiz}} = 0.729\left[\frac{g\rho_l(\rho_l - \rho_v)h^*_{fg}k_l^3}{\mu_l(T_{\text{sat}} - T_s)D}\right]^{1/4}$$

$$= 0.729\left[\frac{(32.2 \text{ ft/s}^2)(62.12 \text{ lbm/ft}^3)(62.12 - 0.0025 \text{ lbm/ft}^3)(1047 \text{ Btu/lbm})(0.358 \text{ Btu/h}\cdot\text{ft}\cdot°\text{F})^3}{[(1 \text{ h}/3600 \text{ s})^2](1.842 \text{ lbm/ft}\cdot\text{h})(95-85)°\text{F}(1/12 \text{ ft})}\right]^{1/4}$$

$$= 1942 \text{ Btu/h}\cdot\text{ft}^2\cdot°\text{F}$$

The heat transfer surface area of the tube per unit length is

$$A_s = \pi DL = \pi(1/12 \text{ ft})(1 \text{ ft}) = 0.2618 \text{ ft}^2$$

Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA_s(T_{\text{sat}} - T_s) = (1942 \text{ Btu/h}\cdot\text{ft}^2\cdot°\text{F})(0.2618 \text{ ft}^2)(95-85)°\text{F} = \mathbf{5084 \text{ Btu/h}}$$

(*b*) The rate of condensation of steam is determined from

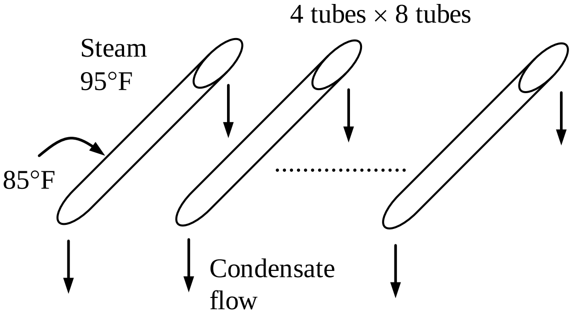
$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h^*_{fg}} = \frac{5084 \text{ Btu/h}}{1047 \text{ Btu/lbm}} = \mathbf{4.856 \text{ lbm/h}}$$

10-48E Saturated steam at a saturation temperature of T_{sat} = 95°F condenses on the outer surfaces of 20 horizontal pipes which are maintained at 85°F by circulating cooling water and arranged in a rectangular array of 4 pipes high and 5 pipes wide. The rate of heat transfer to the cooling water and the rate of condensation per unit length of the pipes are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The pipes are isothermal.

Properties The properties of water at the saturation temperature of 95°F are h_{fg} = 1040 Btu/lbm and ρ_v = 0.0025 lbm/ft^3. The properties of liquid water at the film temperature of $T_f = (T_{\text{sat}} + T_s)/2 = (95 + 85)/2 =$ 90°F are (Table A-9E),

$$\rho_l = 62.12 \text{ lbm/ft}^3$$
$$\mu_l = 1.842 \text{ lbm/ft}\cdot\text{h}$$
$$\nu_l = \mu_l/\rho_l = 0.02965 \text{ ft}^2/\text{h}$$
$$\text{C}_{pl} = 0.999 \text{ Btu/lbm}\cdot°\text{F}$$
$$k_l = 0.358 \text{ Btu/h}\cdot\text{ft}\cdot°\text{F}$$



Analysis The modified latent heat of vaporization is

$$h^*_{fg} = h_{fg} + 0.68C_{pl}(T_{\text{sat}} - T_s)$$
$$= 1040 \text{ Btu/lbm} + 0.68 \times (0.999 \text{ Btu/lbm}\cdot°\text{F})(95-85)°\text{F} = 1047 \text{ Btu/lbm}$$

The heat transfer coefficient for condensation on a single horizontal pipe is

$$h = h_{\text{horiz}} = 0.729\left[\frac{g\rho_l(\rho_l - \rho_v)h^*_{fg}k_l^3}{\mu_l(T_{\text{sat}} - T_s)D}\right]^{1/4}$$
$$= 0.729\left[\frac{(32.2\text{ ft/s}^2)(62.12\text{ lbm/ft}^3)(62.12 - 0.0025\text{ lbm/ft}^3)(1047\text{ Btu/lbm})(0.358\text{ Btu/h}\cdot\text{ft}\cdot°\text{F})^3}{[(1\text{ h}/3600\text{ s})^2](1.842\text{ lbm/ft}\cdot\text{h})(95-85)°\text{F}(1/12\text{ ft})}\right]^{1/4}$$
$$= 1942\text{ Btu/h}\cdot\text{ft}^2\cdot°\text{F}$$

Then the average heat transfer coefficient for a 4-pipe high vertical tier becomes

$$h_{\text{horiz, N tubes}} = \frac{1}{N^{1/4}}h_{\text{horiz, 1 tube}} = \frac{1}{4^{1/4}}(1942 \text{ Btu/h}\cdot\text{ft}^2\cdot°\text{F}) = 1373 \text{ Btu/h}\cdot\text{ft}^2\cdot°\text{F}$$

The surface area for all 32 pipes per unit length of the pipes is

$$A_s = N_{\text{total}}\pi DL = 32\pi(1/12\text{ ft})(1\text{ ft}) = 8.378\text{ ft}^2$$

Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA_s(T_{\text{sat}} - T_s) = (1373\text{ Btu/h.ft}^2\cdot°\text{F})(8.378\text{ ft}^2)(95-85)°\text{F} = \mathbf{115{,}000\text{ Btu/h}}$$

(*b*) The rate of condensation of steam is determined from

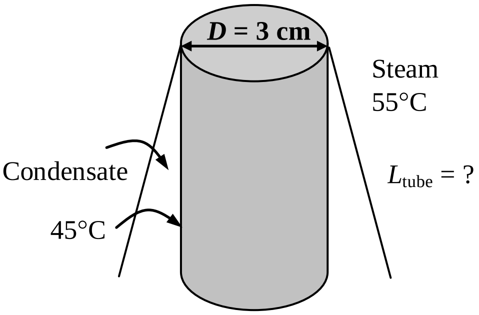
$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h^*_{fg}} = \frac{115{,}000\text{ Btu/h}}{1047\text{ Btu/lbm}} = \mathbf{109.9\text{ lbm/h}}$$

10-49 Saturated steam at a saturation temperature of T_{sat} = 55°C condenses on the outer surface of a vertical tube which is maintained at 45°C. The required tube length to condense steam at a rate of 10 kg/h is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The tube is isothermal. **3** The vertical tube can be treated as a vertical plate. **4** The density of vapor is much smaller than the density of liquid, $\rho_v << \rho_l$.

Properties The properties of water at the saturation temperature of 55°C are $h_{fg} = 2371\times10^3$ J/kg and ρ_v = 0.1045 kg/m^3. The properties of liquid water at the film temperature of $T_f = (T_{\text{sat}} + T_s)/2 = (55 + 45)/2$ = 50°C are (Table A-9),

$$\rho_l = 988.1\ \text{kg/m}^3$$
$$\mu_l = 0.547\times10^{-3}\ \text{kg/m}\cdot\text{s}$$
$$\nu_l = \mu_l/\rho_l = 0.554\times10^{-6}\ \text{m}^2/\text{s}$$
$$\text{C}_{pl} = 4181\ \text{J/kg}\cdot{}^\circ\text{C}$$
$$k_l = 0.644\ \text{W/m}\cdot{}^\circ\text{C}$$



Analysis The modified latent heat of vaporization is

$$h^*_{fg} = h_{fg} + 0.68C_{pl}(T_{\text{sat}} - T_s)$$
$$= 2371\times10^3\ \text{J/kg} + 0.68\times4181\ \text{J/kg}\cdot{}^\circ\text{C}(55-45)^\circ\text{C} = 2399\times10^3\ \text{J/kg}$$

The Reynolds number is determined from its definition to be

$$\text{Re} = \frac{4\dot{m}}{p\mu_l} = \frac{4(10/3600\ \text{kg/s})}{\pi(0.03\ \text{m})(0.547\times10^{-3}\ \text{kg/m}\cdot\text{s})} = 215.5$$

which is between 30 and 1800. Therefore the condensate flow is wavy laminar, and the condensation heat transfer coefficient is determined from

$$h = h_{\text{vertical,wavy}} = \frac{\text{Re}\,k_l}{1.08\,\text{Re}^{1.22} - 5.2}\left(\frac{g}{\nu_l^2}\right)^{1/3}$$
$$= \frac{215.5\times(0.644\ \text{W/m}\cdot{}^\circ\text{C})}{1.08(215.5)^{1.22} - 5.2}\left(\frac{9.8\ \text{m/s}^2}{(0.554\times10^{-6}\ \text{m}^2/\text{s})^2}\right)^{1/3} = 5644\ \text{W/m}^2\cdot{}^\circ\text{C}$$

The rate of heat transfer during this condensation process is

$$\dot{Q} = \dot{m}h^*_{fg} = (10/3600\ \text{kg/s})(2399\times10^3\ \text{J/kg}) = 6{,}664\ \text{W}$$

Heat transfer can also be expressed as

$$\dot{Q} = hA_s(T_{\text{sat}} - T_s) = h(\pi DL)(T_{\text{sat}} - T_s)$$

Then the required length of the tube becomes

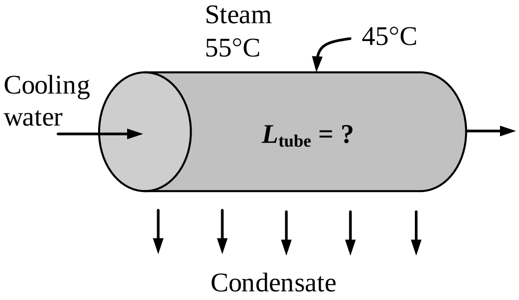
$$L = \frac{\dot{Q}}{h(\pi D)(T_{\text{sat}} - T_s)} = \frac{6664\ \text{W}}{(5844\ \text{W/m}^2\cdot{}^\circ\text{C})\pi(0.03\ \text{m})(55-45)^\circ\text{C}} = \mathbf{1.21\ m}$$

10-50 Saturated steam at a saturation temperature of T_{sat} = 55°C condenses on the outer surface of a horizontal tube which is maintained at 45°C. The required tube length to condense steam at a rate of 10 kg/h is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The tube is isothermal.

Properties The properties of water at the saturation temperature of 55°C are $h_{fg} = 2371\times10^3$ J/kg and $\rho_v = 0.1045$ kg/m^3. The properties of liquid water at the film temperature of $T_f = (T_{sat} + T_s)/2 = (55 + 45)/2$ = 50°C are (Table A-9),

$$\rho_l = 988.1 \text{ kg/m}^3$$
$$\mu_l = 0.547\times10^{-3} \text{ kg/m}\cdot\text{s}$$
$$\nu_l = \mu_l/\rho_l = 0.554\times10^{-6} \text{ m}^2/\text{s}$$
$$C_{pl} = 4181 \text{ J/kg}\cdot°\text{C}$$
$$k_l = 0.644 \text{ W/m}\cdot°\text{C}$$



Analysis The modified latent heat of vaporization is

$$h^*_{fg} = h_{fg} + 0.68C_{pl}(T_{sat} - T_s)$$
$$= 2371\times10^3 \text{ J/kg} + 0.68\times4181 \text{ J/kg}\cdot°\text{C}(55-45)°\text{C} = 2399\times10^3 \text{ J/kg}$$

Noting that the tube is horizontal, the condensation heat transfer coefficient is determined from

$$h = h_{\text{horizontal}} = 0.729\left[\frac{g\rho_l(\rho_l - \rho_v)h^*_{fg}k_l^3}{\mu_l(T_{sat} - T_s)D}\right]^{1/4}$$
$$= 0.729\left[\frac{(9.8 \text{ m/s}^2)(988.1 \text{ kg/m}^3)(988.1 - 0.10 \text{ kg/m}^3)(2399\times10^3 \text{ J/kg})(0.644 \text{ W/m}\cdot°\text{C})^3}{(0.547\times10^{-3} \text{ kg/m}\cdot\text{s})(55-45)°\text{C}(0.03 \text{ m})}\right]^{1/4}$$
$$= 10{,}135 \text{ W/m}^2.°\text{C}$$

The rate of heat transfer during this condensation process is

$$\dot{Q} = \dot{m}h^*_{fg} = (10/3600 \text{ kg/s})(2399\times10^3 \text{ J/kg}) = 6{,}664 \text{ W}$$

Heat transfer can also be expressed as

$$\dot{Q} = hA_s(T_{sat} - T_s) = h(\pi DL)(T_{sat} - T_s)$$

Then the required length of the tube becomes

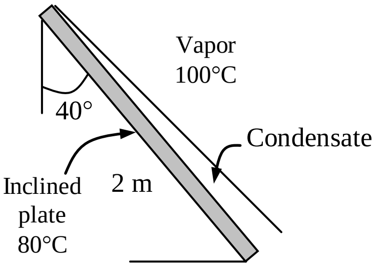
$$L = \frac{\dot{Q}}{h(\pi D)(T_{sat} - T_s)} = \frac{6664 \text{ W}}{(10{,}135 \text{ W/m}^2\cdot°\text{C})\pi(0.03 \text{ m})(55-45)°\text{C}} = \mathbf{0.70 \text{ m}}$$

10-51 Saturated steam at a saturation temperature of T_{sat} = 100°C condenses on a plate which is tilted 40° from the vertical and maintained at 80°C by circulating cooling water through the other side. The rate of heat transfer to the plate and the rate of condensation of the steam are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The plate is isothermal. **3** The condensate flow is wavy-laminar over the entire plate (this assumption will be verified). **4** The density of vapor is much smaller than the density of liquid, $\rho_v << \rho_l$.

Properties The properties of water at the saturation temperature of 100°C are $h_{fg} = 2257\times10^3$ J/kg and ρ_v = 0.60 kg/m^3. The properties of liquid water at the film temperature of $T_f = (T_{sat} + T_s)/2 = (100 + 80)/2 =$ 90°C are (Table A-9),

$$\rho_l = 965.3 \text{ kg/m}^3$$
$$\mu_l = 0.315\times10^{-3} \text{kg/m}\cdot\text{s}$$
$$\nu_l = \mu_l/\rho_l = 0.326\times10^{-6} \text{m}^2/\text{s}$$
$$C_{pl} = 4206 \text{ J/kg}\cdot°\text{C}$$
$$k_l = 0.675 \text{ W/m}\cdot°\text{C}$$



Analysis The modified latent heat of vaporization is

$$h^*_{fg} = h_{fg} + 0.68C_{pl}(T_{sat} - T_s)$$
$$= 2257\times10^3 \text{ J/kg} + 0.68\times4206 \text{ J/kg}\cdot°\text{C}(100-80)°\text{C} = 2{,}314\times10^3 \text{ J/kg}$$

Assuming wavy-laminar flow, the Reynolds number is determined from the vertical plate relation by replacing g by $g\cos\theta$ where θ = 60° to be

$$\text{Re} = \text{Re}_{\text{tilted,wavy}} = \left[4.81 + \frac{3.70Lk_l(T_{sat}-T_s)}{\mu_l h^*_{fg}}\left(\frac{g\cos\theta}{\nu_l^2}\right)^{1/3}\right]^{0.820}$$
$$= \left[4.81 + \frac{3.70\times(2\text{ m})\times(0.675 \text{ W/m}\cdot°\text{C})\times(100-80)°\text{C}}{(0.315\times10^{-3} \text{ kg/m}\cdot\text{s})(2314\times10^3 \text{ J/kg})}\left(\frac{(9.8 \text{ m/s}^2)\cos 40}{(0.326\times10^{-6} \text{ m}^2/\text{s})^2}\right)^{1/3}\right]^{0.82} = 1197$$

which is between 30 and 1800, and thus our assumption of wavy laminar flow is verified. Then the condensation heat transfer coefficient is determined from

$$h = h_{\text{tilted,wavy}} = \frac{\text{Re}\,k_l}{1.08\,\text{Re}^{1.22} - 5.2}\left(\frac{g\cos\theta}{\nu_l^2}\right)^{1/3}$$
$$= \frac{1197\times(0.675 \text{ W/m}\cdot°\text{C})}{1.08(1197)^{1.22} - 5.2}\left(\frac{(9.8 \text{ m/s}^2)\cos 40}{(0.326\times10^{-6} \text{ m}^2/\text{s})^2}\right)^{1/3} = \mathbf{5438 \text{ W/m}^2\cdot°\text{C}}$$

The heat transfer surface area of the plate is: $A = w\times L = (2 \text{ m})(2 \text{ m}) = 4 \text{ m}^2$.

Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA(T_{sat} - T_s) = (5438 \text{ W/m}^2\cdot°\text{C})(4 \text{ m}^2)(100-80)°\text{C} = 435{,}000 \text{ W}$$

(*b*) The rate of condensation of steam is determined from

$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h^*_{fg}} = \frac{435{,}000 \text{ J/s}}{2314\times10^3 \text{ J/kg}} = \mathbf{0.188 \text{ kg/s}}$$

Discussion We could also determine the heat transfer coefficient from $h_{\text{inclined}} = h_{\text{vert}}(\cos\theta)^{1/4}$.

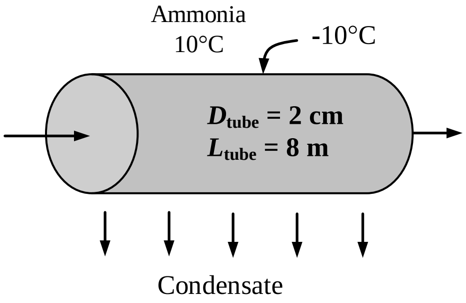
10-53 Saturated ammonia vapor at a saturation temperature of T_{sat} = 10°C condenses on the outer surface of a horizontal tube which is maintained at -10°C. The rate of heat transfer from the ammonia and the rate of condensation of ammonia are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The tube is isothermal.

Properties The properties of ammonia at the saturation temperature of 10°C are $h_{fg} = 1226\times10^3$ J/kg and ρ_v = 4.870 kg/m^3 (Table A-11). The properties of liquid ammonia at the film temperature of $T_f = (T_{sat} + T_s)/2 = (10 + (-10))/2 = 0°\text{C}$ are (Table A-11),

$$\rho_l = 638.6\ \text{kg/m}^3$$
$$\mu_l = 1.896\times10^{-4}\ \text{kg/m}\cdot\text{s}$$
$$\nu_l = 0.2969\times10^{-6}\ \text{m}^2/\text{s}$$
$$C_{pl} = 4617\ \text{J/kg}\cdot°\text{C}$$
$$k_l = 0.5390\ \text{W/m}\cdot°\text{C}$$



Analysis The modified latent heat of vaporization is

$$h^*_{fg} = h_{fg} + 0.68C_{pl}(T_{sat} - T_s)$$
$$= 1226\times10^3\ \text{J/kg} + 0.68\times4617\ \text{J/kg}\cdot°\text{C}[10-(-10)]°\text{C} = 1288\times10^3\ \text{J/kg}$$

Noting that the tube is horizontal, the condensation heat transfer coefficient is determined from

$$h = h_{\text{horizontal}} = 0.729\left[\frac{g\rho_l(\rho_l-\rho_v)h^*_{fg}k_l^3}{\mu_l(T_{sat}-T_s)D}\right]^{1/4}$$
$$= 0.729\left[\frac{(9.81\ \text{m/s}^2)(638.6\ \text{kg/m}^3)(638.6-4.870\ \text{kg/m}^3)(1288\times10^3\ \text{J/kg})(0.5390\ \text{W/m}\cdot°\text{C})^3}{(1.896\times10^{-4}\ \text{kg/m}\cdot\text{s})[10-(-10)]°\text{C}(0.02\ \text{m})}\right]^{1/4}$$
$$= 7390\ \text{W/m}^2.°\text{C}$$

The heat transfer surface area of the tube is

$$A_s = \pi DL = \pi(0.02\ \text{m})(8\ \text{m}) = 0.5027\ \text{m}^2$$

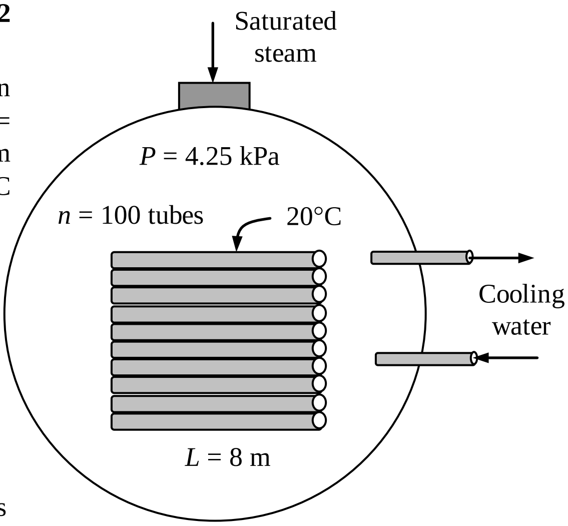
Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA_s(T_{sat}-T_s) = (7390\ \text{W/m}^2.°\text{C})(0.5027\ \text{m}^2)[10-(-10)]°\text{C} = \mathbf{74{,}300\ W}$$

(*b*) The rate of condensation of ammonia is determined from

$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h^*_{fg}} = \frac{74{,}300\ \text{J/s}}{1288\times10^3\ \text{J/kg}} = \mathbf{0.0577\ kg/s}$$

10-54 Saturated steam at a pressure of 4.25 kPa and thus at a saturation temperature of T_{sat} = 30°C (Table A-9) condenses on the outer surfaces of 100 horizontal tubes arranged in a 10×10 square array maintained at 20°C by circulating cooling water. The rate of heat transfer to the cooling water and the rate of condensation of steam on the tubes are to be determined.



Assumptions **1** Steady operating conditions exist. **2** The tubes are isothermal.

Properties The properties of water at the saturation temperature of 30°C are $h_{fg} = 2431\times10^3$ J/kg and ρ_v = 0.030 kg/m^3. The properties of liquid water at the film temperature of $T_f = (T_{\text{sat}} + T_s)/2 = (30 + 20)/2$ = 25°C are (Table A-9),

$$\rho_l = 997.0 \text{ kg/m}^3$$
$$\mu_l = 0.891\times10^{-3} \text{ kg/m}\cdot\text{s}$$
$$\nu_l = \mu_l/\rho_l = 0.894\times10^{-6} \text{ m}^2/\text{s}$$
$$C_{pl} = 4180 \text{ J/kg}\cdot°\text{C}$$
$$k_l = 0.607 \text{ W/m}\cdot°\text{C}$$

Analysis (*a*) The modified latent heat of vaporization is

$$\begin{aligned} h^*_{fg} &= h_{fg} + 0.68C_{pl}(T_{\text{sat}} - T_s) \\ &= 2431\times10^3 \text{ J/kg} + 0.68\times4180 \text{ J/kg}\cdot°\text{C}(30-20)°\text{C} = 2{,}459\times10^3 \text{ J/kg} \end{aligned}$$

The heat transfer coefficient for condensation on a single horizontal tube is

$$h = h_{\text{horizontal}} = 0.729\left[\frac{g\rho_l(\rho_l - \rho_v)h^*_{fg}k_l^3}{\mu_l(T_{\text{sat}} - T_s)D}\right]^{1/4}$$

$$= 0.729\left[\frac{(9.8 \text{ m/s}^2)(997 \text{ kg/m}^3)(997 - 0.03 \text{ kg/m}^3)(2459\times10^3 \text{ J/kg})(0.607 \text{ W/m}\cdot°\text{C})^3}{(0.891\times10^{-3} \text{ kg/m}\cdot\text{s})(30-20)°\text{C}(0.03 \text{ m})}\right]^{1/4}$$

$$= 8674 \text{ W/m}^2.°\text{C}$$

Then the average heat transfer coefficient for a 10-pipe high vertical tier becomes

$$h_{\text{horiz, N tubes}} = \frac{1}{N^{1/4}}h_{\text{horiz, 1 tube}} = \frac{1}{10^{1/4}}(8674 \text{ W/m}^2\cdot°\text{C}) = 4878 \text{ W/m}^2\cdot°\text{C}$$

The surface area for all 100 tubes is

$$A_s = N_{\text{total}}\pi DL = 100\pi(0.03 \text{ m})(8 \text{ m}) = 75.40 \text{ m}^2$$

Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA_s(T_{\text{sat}} - T_s) = (4878 \text{ W/m}^2.°\text{C})(75.40 \text{ m}^2)(30-20)°\text{C} = 3{,}678{,}000 \text{ W} = \mathbf{3678\ kW}$$

(*b*) The rate of condensation of steam is determined from

$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h^*_{fg}} = \frac{3{,}678{,}000 \text{ J/s}}{2459\times10^3 \text{ J/kg}} = \mathbf{1.496\ kg/s}$$

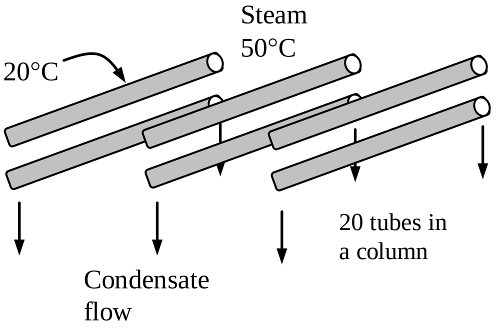
10-56 Saturated steam at a saturation temperature of T_{sat} = 50°C condenses on the outer surfaces of a tube bank with 20 tubes in each column maintained at 20°C. The average heat transfer coefficient and the rate of condensation of steam on the tubes are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The tubes are isothermal.

Properties The properties of water at the saturation temperature of 50°C are $h_{fg} = 2383\times10^3$ J/kg and ρ_v = 0.0831 kg/m^3. The properties of liquid water at the film temperature of $T_f = (T_{sat} + T_s)/2 = (50 + 20)/2$ = 35°C are (Table A-9),



$$\rho_l = 994.0 \text{ kg/m}^3$$
$$\mu_l = 0.720\times10^{-3} \text{kg/m}\cdot\text{s}$$
$$\nu_l = \mu_l/\rho_l = 0.724\times10^{-6} \text{m}^2/\text{s}$$
$$\text{C}_{pl} = 4178 \text{ J/kg}\cdot°\text{C}$$
$$k_l = 0.623 \text{ W/m}\cdot°\text{C}$$

Analysis (*a*) The modified latent heat of vaporization is

$$\begin{aligned} h^*_{fg} &= h_{fg} + 0.68C_{pl}(T_{sat} - T_s) \\ &= 2383\times10^3 \text{ J/kg} + 0.68\times4178 \text{ J/kg}\cdot°\text{C}(50-20)°\text{C} \\ &= 2468\times10^3 \text{ J/kg} \end{aligned}$$

The heat transfer coefficient for condensation on a single horizontal tube is

$$\begin{aligned} h = h_{\text{horizontal}} &= 0.729\left[\frac{g\rho_l(\rho_l-\rho_v)h^*_{fg}k_l^3}{\mu_l(T_{sat}-T_s)D}\right]^{1/4} \\ &= 0.729\left[\frac{(9.8 \text{ m/s}^2)(994 \text{ kg/m}^3)(994-0.08 \text{ kg/m}^3)(2468\times10^3 \text{ J/kg})(0.623 \text{ W/m}\cdot°\text{C})^3}{(0.720\times10^{-3} \text{ kg/m}\cdot\text{s})(50-20)°\text{C}(0.015 \text{ m})}\right]^{1/4} \\ &= 8425 \text{ W/m}^2\cdot°\text{C} \end{aligned}$$

Then the average heat transfer coefficient for a 10-pipe high vertical tier becomes

$$h_{\text{horiz, N tubes}} = \frac{1}{N^{1/4}}h_{\text{horiz, 1 tube}} = \frac{1}{20^{1/4}}(8425 \text{ W/m}^2\cdot°\text{C}) = \mathbf{3984\ W/m^2\cdot°C}$$

The surface area for all 20 tubes per unit length is

$$A_s = N_{\text{total}}\pi DL = 20\pi(0.015 \text{ m})(1 \text{ m}) = 0.9425 \text{ m}^2$$

Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA_s(T_{sat} - T_s) = (2794 \text{ W/m}^2\cdot°\text{C})(0.9425 \text{ m}^2)(50-20)°\text{C} = 112{,}650 \text{ W}$$

(*b*) The rate of condensation of steam is determined from

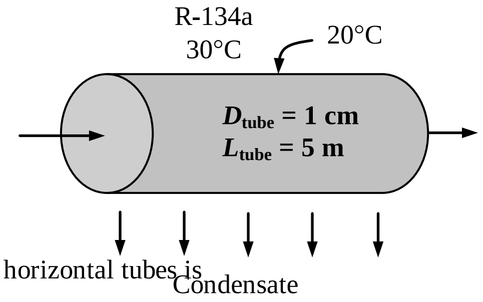
$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h^*_{fg}} = \frac{112{,}650 \text{ J/s}}{2468\times10^3 \text{ J/kg}} = \mathbf{0.0456\ kg/s}$$

10-57 Saturated refrigerant-134a vapor at a saturation temperature of T_{sat} = 30°C condenses inside a horizontal tube which is maintained at 20°C. The fraction of the refrigerant that will condense at the end of the tube is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The tube is isothermal. **3** The vapor velocity is low so that $\text{Re}_{\text{vapor}} < 35{,}000$.

Properties The properties of refrigerant-134a at the saturation temperature of 30°C are $h_{fg} = 173.1\times10^3$ J/kg and ρ_v = 37.53 kg/m^3. The properties of liquid R-134a at the film temperature of $T_f = (T_{\text{sat}} + T_s)/2 = (30 + 20)/2 = 25°\text{C}$ are (Table A-10)

$$\rho_l = 1207\ \text{kg/m}^3$$
$$\mu_l = 2.012\times10^{-4}\ \text{kg/m.s}$$
$$\nu_l = \mu_l/\rho_l = 0.1667\times10^{-6}\ \text{m}^2/\text{s}$$
$$\text{C}_{pl} = 1427\ \text{J/kg.°C}$$
$$k_l = 0.08325\ \text{W/m.°C}$$



Analysis The heat transfer coefficient for condensation inside horizontal tubes is

$$h = h_{\text{internal}} = 0.555\left[\frac{g\rho_l(\rho_l-\rho_v)k_l^3}{\mu_l(T_{\text{sat}}-T_s)}\left(h_{fg}+\frac{3}{8}C_{pl}(T_{\text{sat}}-T_s)\right)\right]^{1/4}$$

$$= 0.555\left[\frac{(9.81\,\text{m/s}^2)(1207\,\text{kg/m}^3)(1207-37.53)\,\text{kg/m}^3)(0.08325\,\text{W/m}\cdot°\text{C})^3}{(2.012\times10^{-4}\ \text{kg/m}\cdot\text{s})(30-20)°\text{C}}\right.$$
$$\left.\times\left(173.1\times10^3\ \text{J/kg}+\frac{3}{8}(1427\ \text{J/kg}\cdot°\text{C})(30-20)°\text{C}\right)\right]^{1/4}$$
$$= 509.2\ \text{W/m}^2\cdot°\text{C}$$

The heat transfer surface area of the pipe is

$$A_s = \pi DL = \pi(0.01\,\text{m})(5\,\text{m}) = 0.1571\,\text{m}^2$$

Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA_s(T_{\text{sat}}-T_s) = (509.2\,\text{W/m}^2\cdot°\text{C})(0.1571\,\text{m}^2)(30-20)°\text{C} = 800.0\,\text{W}$$

The modified latent heat of vaporization in this case is, as indicated in the *h* relation,

$$h_{fg}^* = h_{fg}+\frac{3}{8}C_{pl}(T_{\text{sat}}-T_s) = 173.1\times10^3\ \text{J/kg}+\frac{3}{8}(1427\ \text{J/kg}\cdot°\text{C})(30-20)°\text{C} = 178.5\times10^3\ \text{J/kg}$$

Then the rate of condensation becomes

$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h_{fg}^*} = \frac{800\ \text{J/s}}{178.5\times10^3\ \text{J/kg}} = 0.004482\ \text{kg/s} = 0.2689\ \text{kg/min}$$

Therefore, the fraction of the refrigerant that will condense at the end of the tube is

$$\text{Fraction condensed} = \frac{\dot{m}_{\text{condensed}}}{\dot{m}_{\text{total}}} = \frac{0.2689\ \text{kg/min}}{2.5\ \text{kg/min}} = \mathbf{0.108\ \ (or\ 10.8\%)}$$

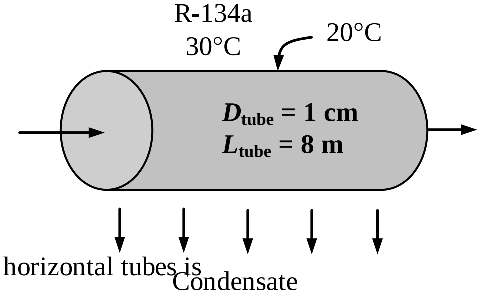
Discussions Note that we used the modified h_{fg}^* instead of just h_{fg} in heat transfer calculations to account for heat transfer due to the cooling of the condensate below the saturation temperature.

10-58 Saturated refrigerant-134a vapor condenses inside a horizontal tube maintained at a uniform temperature. The fraction of the refrigerant that will condense at the end of the tube is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The tube is isothermal. **3** The vapor velocity is low so that $\text{Re}_{\text{vapor}} < 35{,}000$.

Properties The properties of refrigerant-134a at the saturation temperature of 30°C are $h_{fg} = 173.1\times10^3$ J/kg and ρ_v = 37.53 kg/m^3. The properties of liquid R-134a at the film temperature of $T_f = (T_{\text{sat}} + T_s)/2 = (30 + 20)/2 = 25°\text{C}$ are (Table A-10)

$$\rho_l = 1207 \text{ kg/m}^3$$
$$\mu_l = 2.012\times10^{-4} \text{ kg/m.s}$$
$$\nu_l = \mu_l / \rho_l = 0.1667\times10^{-6} \text{ m}^2\text{/s}$$
$$C_{pl} = 1427 \text{ J/kg.°C}$$
$$k_l = 0.08325 \text{ W/m.°C}$$



Analysis The heat transfer coefficient for condensation inside horizontal tubes is

$$h = h_{\text{internal}} = 0.555\left[\frac{g\rho_l(\rho_l-\rho_v)k_l^3}{\mu_l(T_{\text{sat}}-T_s)}\left(h_{fg}+\frac{3}{8}C_{pl}(T_{\text{sat}}-T_s)\right)\right]^{1/4}$$

$$= 0.555\left[\frac{(9.81\text{ m/s}^2)(1207\text{ kg/m}^3)(1207-37.53)\text{ kg/m}^3)(0.08325\text{ W/m}\cdot°\text{C})^3}{(2.012\times10^{-4}\text{ kg/m}\cdot\text{s})(30-20)°\text{C}}\right.$$
$$\left.\times\left(173.1\times10^3\text{ J/kg}+\frac{3}{8}(1427\text{ J/kg}\cdot°\text{C})(30-20)°\text{C}\right)\right]^{1/4}$$

$$= 509.2\text{ W/m}^2\cdot°\text{C}$$

The heat transfer surface area of the pipe is

$$A_s = \pi DL = \pi(0.01\text{ m})(8\text{ m}) = 0.2513\text{ m}^2$$

Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA_s(T_{\text{sat}}-T_s) = (509.2\text{ W/m}^2\cdot°\text{C})(0.2513\text{ m}^2)(30-20)°\text{C} = 1280\text{ W}$$

The modified latent heat of vaporization in this case is, as indicated in the *h* relation,

$$h^*_{fg} = h_{fg}+\frac{3}{8}C_{pl}(T_{\text{sat}}-T_s) = 173.1\times10^3\text{ J/kg}+\frac{3}{8}(1427\text{ J/kg}\cdot°\text{C})(30-20)°\text{C} = 178.5\times10^3\text{ J/kg}$$

Then the rate of condensation becomes

$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h_{fg}} = \frac{1280\text{ J/s}}{178.5\times10^3\text{ J/kg}} = 0.007169\text{ kg/s} = 0.4301\text{ kg/min}$$

Therefore, the fraction of the refrigerant that will condense at the end of the tube is

$$\text{Fraction condensed} = \frac{\dot{m}_{\text{condensed}}}{\dot{m}_{\text{total}}} = \frac{0.4301\text{ kg/min}}{2.5\text{ kg/min}} = \mathbf{0.172\ \ (or\ 17.2\%)}$$

Special Topic: Heat Pipes

10-60C A heat pipe is a simple device with no moving parts which can transfer large quantities of heat over fairly large distances essentially at a constant temperature without requiring any power input. A heat pipe is basically a sealed slender tube containing a wick structure lined on the inner surface and a small amount of fluid such as water at the saturated state. It is composed of three sections: the evaporator section at one and where heat is absorbed and the fluid is vaporized, a condenser section at the other end where the vapor is condensed and heat is rejected, and the adiabatic section in between where the vapor and the liquid phases of the fluid flow in opposite directions through the core and the wick, respectively, to complete the cycle with no significant heat transfer between the fluid and the surrounding medium.

10-61C The boiling and condensation processes are associated with extremely high heat transfer coefficients, and thus it is natural to expect the heat pipe to be an extremely effective heat transfer device since its operation is based on alternate boiling and condensation of the working fluid.

10-62C The non-condensable gases such as air degrade the performance of the heat pipe, and can destroy it in a short time.

10-63C The heat pipes with water as the working fluid are designed to remove heat at temperatures below the boiling temperature of water at atmospheric pressure (i.e., 100°C). Therefore, the pressure inside the heat pipe must be maintained below the atmospheric pressure to provide boiling at such temperatures.

10-64C Liquid motion in the wick depends on the dynamic balance between two opposing effects: the capillary pressure which pumps the liquid through the pores, and the internal resistance to flow due to the friction between the mesh surface and the liquid. Small pores increases the capillary action, but it also increases the friction force opposing the fluid motion. At optimum core size, the difference between the capillary force and the friction force is maximum.

10-65C The orientation of the heat pipe affects its performance. The performance of a heat pipe will be best when the capillary and gravity forces act in the same direction (evaporator end down), and it will be worst when these two forces act in opposite directions (evaporator end up).

10-66C The capillary pressure which creates the suction effect to draw the liquid forces the liquid in a heat pipe to move up against the gravity without a pump. For the heat pipes which work against the gravity, it is better to have fine wicks since the capillary pressure is inversely proportional to the effective capillary radius of the mesh.

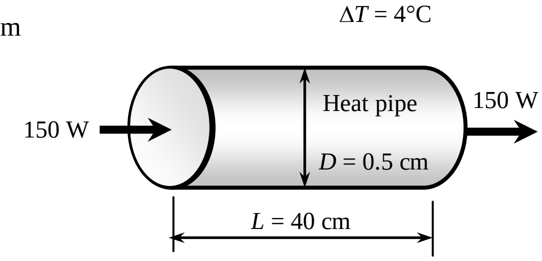
10-67C The most important consideration in the design of a heat pipe is the compatibility of the materials used for the tube, wick and the fluid.

10-68C The major cause for the premature degradation of the performance of some heat pipes is contamination which occurs during the sealing of the ends of the heat pipe tube.

10-69 A 40-cm long cylindrical heat pipe dissipates heat at a rate of 150 W. The diameter and mass of a 40-cm long copper rod that can conduct heat at the same rate are to be determined.

Assumptions Steady operating conditions exist.

Properties The properties of copper at room temperature are ρ = 8950 kg/m^3 and k = 386 W/m.°C.



Analysis The rate of heat transfer through the copper rod can be expressed as

$$\dot{Q} = kA\frac{\Delta T}{L}$$

Solving for the cross-sectional area A and the diameter D gives

$$A = \frac{L}{k\Delta T}\dot{Q} = \frac{0.4\text{ m}}{(386\text{ W/m.°C})(4\text{°C})}(150\text{ W}) = 0.03886\text{ m}^2 = 388.6\text{ cm}^2$$

$$A = \frac{\pi D^2}{4} \longrightarrow D = \sqrt{\frac{4A}{\pi}} = \sqrt{\frac{4(388.6\text{ cm}^2)}{\pi}} = \mathbf{22.2\text{ cm}}$$

The mass of this copper rod is

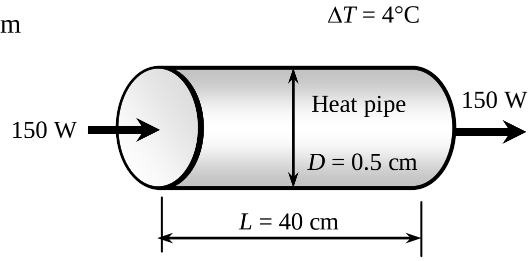
$$m = \rho V = \rho AL = (8950\text{ kg/m}^3)(0.03886\text{ m}^2)(0.4\text{ m}) = \mathbf{139\text{ kg}}$$

10-70 A 40-cm long cylindrical heat pipe dissipates heat at a rate of 150 W. The diameter and mass of a 40-cm long copper rod that can conduct heat at the same rate are to be determined.

Assumptions Steady operating conditions exist.

Properties The properties of copper at room temperature are $\rho = 2702$ kg/m^3 and $k = 237$ W/m.°C.

Analysis The rate of heat transfer through the aluminum rod can be expressed as



$$\dot{Q} = kA\frac{\Delta T}{L}$$

Solving for the cross-sectional area A and the diameter D gives

$$A = \frac{L}{k\Delta T}\dot{Q} = \frac{0.4\text{ m}}{(237\text{ W/m.°C})(4\text{°C})}(150\text{ W}) = 0.06329\text{ m}^2 = 632.9\text{ cm}^2$$

$$A = \frac{\pi D^2}{4} \longrightarrow D = \sqrt{\frac{4A}{\pi}} = \sqrt{\frac{4(632.9\text{ cm}^2)}{\pi}} = \mathbf{28.4\ cm}$$

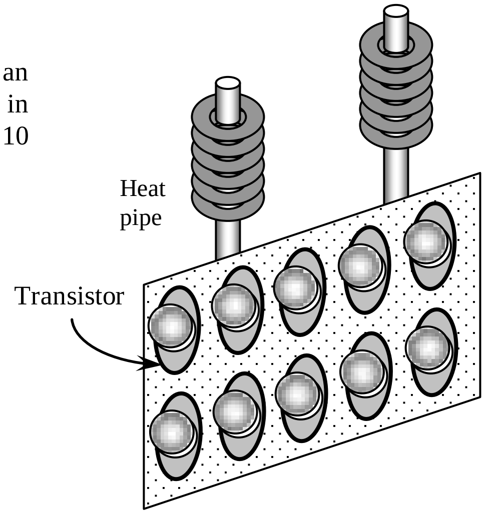
The mass of this aluminum rod is

$$m = \rho V = \rho AL = (2702\text{ kg/m}^3)(0.06329\text{ m}^2)(0.4\text{ m}) = \mathbf{68.4\ kg}$$

10-71E A plate that supports 10 power transistors is to be cooled with heat pipes. The number of pipes need to be attached to this plate is to be determined.

Assumptions Steady operating conditions exist.

Analysis The heat removal rate of heat pipes that have an outside diameter of 0.635 cm and length of 30.5 cm is given in Table 10-5 to be 175 W. The total rate of heat dissipated by 10 transistors each dissipating 35 W is



$$\dot{Q}_{total} = (10)(35\text{ W}) = 350\text{ W}$$

Then the number of heat pipes need to be attached to the plate becomes

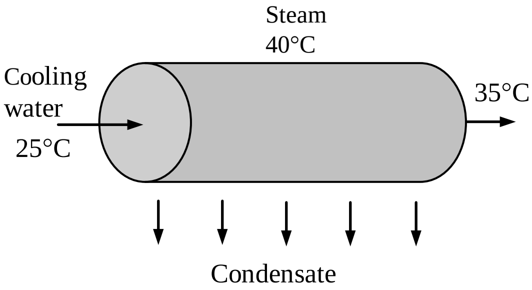
$$n = \frac{\dot{Q}_{total}}{\dot{Q}} = \frac{350\text{ W}}{175\text{ W}} = \mathbf{2}$$

Review Problems

10-72 Steam at a saturation temperature of T_{sat} = 40°C condenses on the outside of a thin horizontal tube. Heat is transferred to the cooling water that enters the tube at 25°C and exits at 35°C. The rate of condensation of steam, the average overall heat transfer coefficient, and the tube length are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The tube can be taken to be isothermal at the bulk mean fluid temperature in the evaluation of the condensation heat transfer coefficient. **3** Liquid flow through the tube is fully developed. **4** The thickness and the thermal resistance of the tube is negligible.

Properties The properties of water at the saturation temperature of 40°C are $h_{\text{fg}} = 2407\times10^3$ J/kg and ρ_v = 0.05 kg/m^3. The properties of liquid water at the film temperature of $T_f = (T_{\text{sat}} + T_s)/2 = (50 + 20)/2$ = 35°C and at the bulk fluid temperature of $T_b = (T_{\text{in}} + T_{\text{out}})/2 = (25 + 35)/2$ = 30°C are (Table A-9),



At 35°C:

$$\rho_l = 994.0 \text{ kg/m}^3$$
$$\mu_l = 0.720\times10^{-3} \text{kg/m}\cdot\text{s}$$
$$C_{pl} = 4178 \text{ J/kg}\cdot°\text{C}$$
$$k_l = 0.623 \text{ W/m}\cdot°\text{C}$$

At 30°C:

$$\rho_l = 996.0 \text{ kg/m}^3$$
$$\nu_l = \mu_l/\rho_l = 0.801\times10^{-6} \text{m}^2\text{/s}$$
$$C_{pl} = 4178 \text{ J/kg}\cdot°\text{C}$$
$$k_l = 0.615 \text{ W/m}\cdot°\text{C}$$
$$\text{Pr} = 5.42$$

Analysis The mass flow rate of water and the rate of heat transfer to the water are

$$\dot{m}_{\text{water}} = \rho V A_c = (996 \text{ kg/m}^3)(2 \text{ m/s})[\pi(0.03 \text{ m})^2/4] = 1.408 \text{ kg/s}$$

$$\dot{Q} = \dot{m}C_p(T_{out} - T_{in}) = (1.408 \text{ kg/s})(4178 \text{ J/kg}\cdot°\text{C})(35-25)°\text{C} = \mathbf{58{,}820\ W}$$

The modified latent heat of vaporization is

$$h^*_{fg} = h_{fg} + 0.68C_{pl}(T_{\text{sat}} - T_s)$$
$$= 2407\times10^3 \text{ J/kg} + 0.68\times4178 \text{ J/kg}\cdot°\text{C}(40-30)°\text{C} = 2435\times10^3 \text{ J/kg}$$

The heat transfer coefficient for condensation on a single horizontal tube is

$$h_o = h_{\text{horizontal}} = 0.729\left[\frac{g\rho_l(\rho_l - \rho_v)h^*_{fg}k_l^3}{\mu_l(T_{\text{sat}} - T_s)D}\right]^{1/4}$$

$$= 0.729\left[\frac{(9.8 \text{ m/s}^2)(994 \text{ kg/m}^3)(994-0.05 \text{ kg/m}^3)(2435\times10^3 \text{ J/kg})(0.623 \text{ W/m}\cdot°\text{C})^3}{(0.720\times10^{-3} \text{ kg/m}\cdot\text{s})(40-30)°\text{C}(0.03 \text{ m})}\right]^{1/4}$$

$$= 9292 \text{ W/m}^2\cdot°\text{C}$$

The average heat transfer coefficient for flow inside the tube is determined as follows:

$$\text{Re} = \frac{V_m D}{\nu} = \frac{(2 \text{ m/s})(0.03 \text{ m})}{0.801\times10^{-6}} = 74{,}906$$

$$\text{Nu} = 0.023\text{Re}^{0.8}\text{Pr}^{0.4} = 0.023(74{,}906)^{0.8}(5.42)^{0.4} = 359$$

$$h_i = \frac{k\text{Nu}}{D} = \frac{(0.615 \text{ W/m}\cdot°\text{C})\times359}{0.03 \text{ m}} = 7357 \text{ W/m}^2\cdot°\text{C}$$

Noting that the thermal resistance of the tube is negligible, the overall heat transfer coefficient becomes

$$U = \frac{1}{1/h_i + 1/h_o} = \frac{1}{1/7357 + 1/9292} = \mathbf{4106\ W/m^2.°C}$$

The logarithmic mean temperature difference is: $\Delta T_{\text{ln}} = \dfrac{\Delta T_i - \Delta T_e}{\ln(\Delta T_i/\Delta T_o)} = \dfrac{15-5}{\ln(15/5)} = 9.10°\text{C}$

The tube length is determined from

$$\dot{Q} = hA_s\Delta T_{\ln} \;\to\; L = \frac{\dot{Q}}{h(\pi D)\Delta T_{\ln}} = \frac{58{,}820\ \text{W}}{(4106\ \text{W/m}^2\cdot{}^\circ\text{C})\pi(0.03\ \text{m})(9.10^\circ\text{C})} = \mathbf{16.7\ m}$$

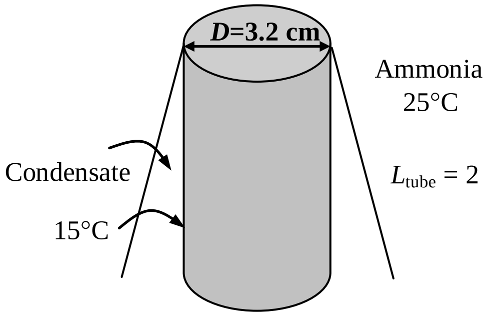
Note that the flow is turbulent, and thus the entry length in this case is *10D* = 0.3 m is much shorter than the total tube length. This verifies our assumption of fully developed flow.

10-73 Saturated ammonia at a saturation temperature of T_{sat} = 25°C condenses on the outer surface of vertical tube which is maintained at 15°C by circulating cooling water. The rate of heat transfer to the coolant and the rate of condensation of ammonia are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The tube is isothermal. **3** The tube can be treated as a vertical plate. **4** The condensate flow is turbulentr over the entire tube (this assumption will be verified). **5** The density of vapor is much smaller than the density of liquid, $\rho_v << \rho_l$.

Properties The properties of ammonia at the saturation temperature of 25°C are $h_{fg} = 1166\times10^3$ J/kg and $\rho_v = 7.809$ kg/m^3. The properties of liquid ammonia at the film temperature of $T_f = (T_{\text{sat}} + T_s)/2 = (25 + 15)/2 = 20$°C are (Table A-11),

$$\begin{aligned}
\rho_l &= 610.2\ \text{kg/m}^3\\
\mu_l &= 1.519\times10^{-4}\ \text{kg/m}\cdot\text{s}\\
\nu_l &= \mu_l/\rho_l = 0.2489\times10^{-6}\ \text{m}^2/\text{s}\\
\text{C}_{pl} &= 4745\ \text{J/kg}\cdot°\text{C}\\
k_l &= 0.4927\ \text{W/m}\cdot°\text{C}\\
\text{Pr}_l &= 1.463
\end{aligned}$$



Analysis (*a*) The modified latent heat of vaporization is

$$\begin{aligned}
h^*_{fg} &= h_{fg} + 0.68C_{pl}(T_{\text{sat}} - T_s)\\
&= 1166\times10^3\ \text{J/kg} + 0.68\times4745\ \text{J/kg}\cdot°\text{C}(25-15)°\text{C} = 1198\times10^3\ \text{J/kg}
\end{aligned}$$

Assuming turbulent flow, the Reynolds number is determined from

$$\begin{aligned}
\text{Re} = \text{Re}_{\text{vertical,turb}} &= \frac{\text{Re}\,k_l}{8750 + 58\,\text{Pr}^{-0.5}(\text{Re}^{0.75} - 253)\mu_l h^*_{fg}}\left(\frac{g}{\nu_l^2}\right)^{1/3}\\
&= \frac{2149\times(0.4827\ \text{W/m}\cdot°\text{C})}{8750 + 58\times1.463^{-0.5}(2149^{0.75} - 253)(1.519\times10^{-4}\ \text{kg/m.s})(1198\times10^3\ \text{J/kg})}\left(\frac{9.81\ \text{m/s}^2}{(0.2489\times10^{-6}\ \text{m}^2/\text{s})^2}\right)^{1/3}\\
&= 2140
\end{aligned}$$

which is greater than 1800, and thus our assumption of turbulent flow is verified. Then the condensation heat transfer coefficient is determined from

$$\begin{aligned}
h = h_{\text{vertical,turbulent}} &= \frac{\text{Re}\,k_l}{8750 + 58\,\text{Pr}^{-0.5}(\text{Re}^{0.75} - 253)}\left(\frac{g}{\nu_l^2}\right)^{1/3}\\
&= \frac{2149\times(0.4827\ \text{W/m}\cdot°\text{C})}{8750 + 58\times1.463^{-0.5}(2149^{0.75} - 253)}\left(\frac{9.81\ \text{m/s}^2}{(0.2489\times10^{-6}\ \text{m}^2/\text{s})^2}\right)^{1/3} = 4871\ \text{W/m}^2\cdot°\text{C}
\end{aligned}$$

The heat transfer surface area of the tube is $A_s = \pi DL = \pi(0.032\ \text{m})(2\ \text{m}) = 0.2011\ \text{m}^2$. Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA_s(T_{\text{sat}} - T_s) = (4871\ \text{W/m}^2\cdot°\text{C})(0.2011\ \text{m}^2)(25-15)°\text{C} = \mathbf{9794\ W}$$

(*b*) The rate of condensation of ammonia is determined from

$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h^*_{fg}} = \frac{9794\ \text{J/s}}{1198\times10^3\ \text{J/kg}} = \mathbf{8.175\times10^{-3}\ kg/s}$$

10-74 There is film condensation on the outer surfaces of 8 horizontal tubes arranged in a horizontal or vertical tier. The ratio of the condensation rate for the cases of the tubes being arranged in a horizontal tier versus in a vertical tier is to be determined.

Assumptions Steady operating conditions exist.

Analysis The heat transfer coefficients for the two cases are related to the heat transfer coefficient on a single horizontal tube by

Horizontal tier: $h_{\text{horizontal tier of N tubes}} = h_{\text{horizontal, 1 tube}}$

Vertical tier: $h_{\text{vertical tier of N tubes}} = \dfrac{h_{\text{horizontal, 1 tube}}}{N^{1/4}}$

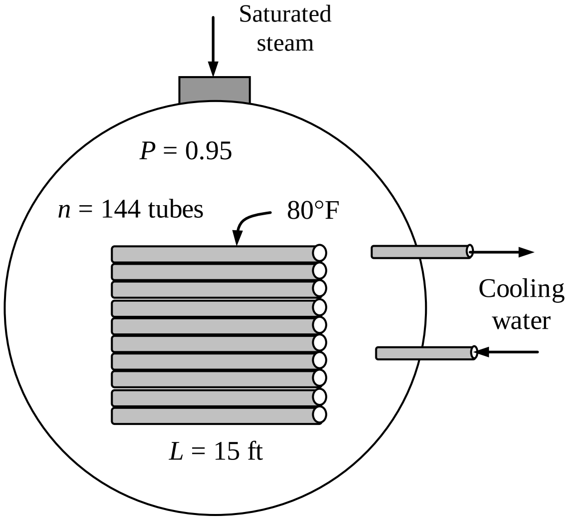
Horizontal tier

Vertical tier

Therefore,

$$\begin{aligned}\text{Ratio} &= \frac{\dot{m}_{\text{horizontal tier of N tubes}}}{\dot{m}_{\text{vertical tier of N tubes}}}\\ &= \frac{h_{\text{horizontal tier of N tubes}}}{h_{\text{vertical tier of N tubes}}}\\ &= \frac{h_{\text{horizontal,1 tube}}}{h_{\text{horizontal,1 tube}} / N^{1/4}}\\ &= N^{1/4}\\ &= 8^{1/4} = \mathbf{1.68}\end{aligned}$$

10-75E Saturated steam at a saturation pressure of 0.95 psia and thus at a saturation temperature of T_{sat} = 100°F (Table A-9E) condenses on the outer surfaces of 144 horizontal tubes which are maintained at 80°F by circulating cooling water and arranged in a 12 × 12 square array. The rate of heat transfer to the cooling water and the rate of condensation of steam are to be determined.



Assumptions **1** Steady operating conditions exist. **2** The tubes are isothermal.

Properties The properties of water at the saturation temperature of 100°F are h_{fg} = 1037 Btu/lbm and ρ_v = 0.00286 lbm/ft^3. The properties of liquid water at the film temperature of $T_f = (T_{sat} + T_s)/2 = (100 + 80)/2 = 90°F$ are (Table A-9E),

$$\rho_l = 62.12 \text{ lbm/ft}^3$$
$$\mu_l = 1.842 \text{ lbm/ft}\cdot\text{h}$$
$$\nu_l = \mu_l / \rho_l = 0.02965 \text{ ft}^2/\text{h}$$
$$C_{pl} = 0.999 \text{ Btu/lbm}\cdot°\text{F}$$
$$k_l = 0.358 \text{ Btu/h}\cdot\text{ft}\cdot°\text{F}$$

Analysis (*a*) The modified latent heat of vaporization is

$$\begin{aligned} h^*_{fg} &= h_{fg} + 0.68C_{pl}(T_{sat} - T_s) \\ &= 1037 \text{ Btu/lbm} + 0.68 \times (0.999 \text{ Btu/lbm}\cdot°\text{F})(100 - 80)°\text{F} \\ &= 1051 \text{ Btu/lbm} \end{aligned}$$

The heat transfer coefficient for condensation on a single horizontal tube is

$$h = h_{horiz} = 0.729\left[\frac{g\rho_l(\rho_l - \rho_v)h^*_{fg}k_l^3}{\mu_l(T_{sat} - T_s)D}\right]^{1/4}$$

$$= 0.729\left[\frac{(32.2 \text{ ft/s}^2)(62.12 \text{ lbm/ft}^3)(62.12 - 0.00286 \text{ lbm/ft}^3)(1051 \text{ Btu/lbm})(0.358 \text{ Btu/h}\cdot\text{ft}\cdot°\text{F})^3}{[(1 \text{ h}/3600 \text{ s})^2](1.842 \text{ lbm/ft}\cdot\text{h})(100 - 80)°\text{F}(1.2/12 \text{ ft})}\right]^{1/4}$$

$$= 1562 \text{ Btu/h}\cdot\text{ft}^2\cdot°\text{F}$$

Then the average heat transfer coefficient for a 4-tube high vertical tier becomes

$$h_{\text{horiz, N tubes}} = \frac{1}{N^{1/4}}h_{\text{horiz, 1 tube}} = \frac{1}{12^{1/4}}(1562 \text{ Btu/h}\cdot\text{ft}^2\cdot°\text{F}) = 839 \text{ Btu/h}\cdot\text{ft}^2\cdot°\text{F}$$

The surface area for all 144 tubes is

$$A_s = N_{total}\pi DL = 144\pi(1.2/12 \text{ ft})(15 \text{ ft}) = 678.6 \text{ ft}^2$$

Then the rate of heat transfer during this condensation process becomes

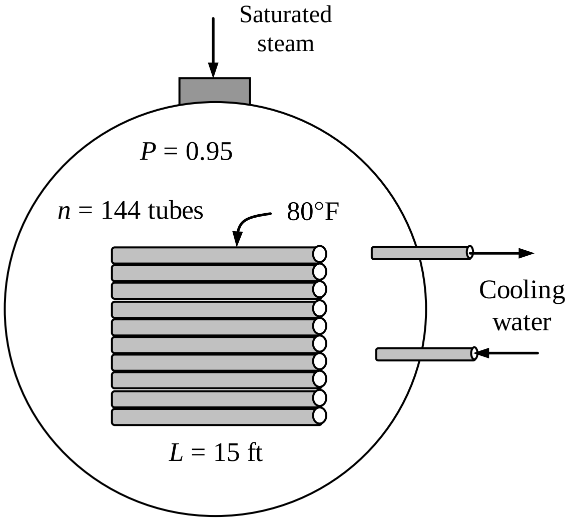
$$\dot{Q} = hA_s(T_{sat} - T_s) = (839 \text{ Btu/h.ft}^2\cdot°\text{F})(678.6 \text{ ft}^2)(100 - 80)°\text{F} = \mathbf{11{,}387{,}000 \text{ Btu/h}}$$

(*b*) The rate of condensation of steam is determined from

$$\dot{m}_{condensation} = \frac{\dot{Q}}{h^*_{fg}} = \frac{11{,}387{,}000 \text{ Btu/h}}{1051 \text{ Btu/lbm}} = \mathbf{10{,}830 \text{ lbm/h}}$$

10-76E Saturated steam at a saturation pressure of 0.95 psia and thus at a saturation temperature of T_{sat} = 100°F (Table A-9E) condenses on the outer surfaces of 144 horizontal tubes which are maintained at 80°F by circulating cooling water and arranged in a 12 × 12 square array. The rate of heat transfer to the cooling water and the rate of condensation of steam are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The tubes are isothermal.



Properties The properties of water at the saturation temperature of 10°F are h_{fg} = 1037 Btu/lbm and ρ_v = 0.00286 lbm/ft^3. The properties of liquid water at the film temperature of $T_f = (T_{\text{sat}} + T_s)/2 = (100 + 80)/2 = 90°\text{F}$ are (Table A-9E),

$$\rho_l = 62.12 \text{ lbm/ft}^3$$
$$\mu_l = 1.842 \text{ lbm/ft}\cdot\text{h}$$
$$\nu_l = \mu_l/\rho_l = 0.02965 \text{ ft}^2/\text{h}$$
$$\text{C}_{pl} = 0.999 \text{ Btu/lbm}\cdot°\text{F}$$
$$k_l = 0.358 \text{ Btu/h}\cdot\text{ft}\cdot°\text{F}$$

Analysis (*a*) The modified latent heat of vaporization is

$$\begin{aligned} h^*_{fg} &= h_{fg} + 0.68C_{pl}(T_{\text{sat}} - T_s) \\ &= 1037 \text{ Btu/lbm} + 0.68 \times (0.999 \text{ Btu/lbm}\cdot°\text{F})(100-80)°\text{F} \\ &= 1051 \text{ Btu/lbm} \end{aligned}$$

The heat transfer coefficient for condensation on a single horizontal tube is

$$h = h_{\text{horiz}} = 0.729\left[\frac{g\rho_l(\rho_l - \rho_v)h^*_{fg}k_l^3}{\mu_l(T_{\text{sat}} - T_s)D}\right]^{1/4}$$

$$= 0.729\left[\frac{(32.2 \text{ ft/s}^2)(62.12 \text{ lbm/ft}^3)(62.12 - 0.00286 \text{ lbm/ft}^3)(1051 \text{ Btu/lbm})(0.358 \text{ Btu/h}\cdot\text{ft}\cdot°\text{F})^3}{[(1 \text{ h}/3600 \text{ s})^2](1.842 \text{ lbm/ft}\cdot\text{h})(100-80)°\text{F}(2.0/12 \text{ ft})}\right]^{1/4}$$

$$= 1374 \text{ Btu/h}\cdot\text{ft}^2\cdot°\text{F}$$

Then the average heat transfer coefficient for a 4-tube high vertical tier becomes

$$h_{\text{horiz, N tubes}} = \frac{1}{N^{1/4}}h_{\text{horiz, 1 tube}} = \frac{1}{12^{1/4}}(1374 \text{ Btu/h}\cdot\text{ft}^2\cdot°\text{F}) = 739 \text{ Btu/h}\cdot\text{ft}^2\cdot°\text{F}$$

The surface area for all 144 tubes is

$$A_s = N_{\text{total}}\pi DL = 144\pi(2/12 \text{ ft})(15 \text{ ft}) = 1131 \text{ ft}^2$$

Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA_s(T_{\text{sat}} - T_s) = (739 \text{ Btu/h.ft}^2\cdot°\text{F})(1131 \text{ ft}^2)(100-80)°\text{F} = \mathbf{16{,}716{,}000\ Btu/h}$$

(*b*) The rate of condensation of steam is determined from

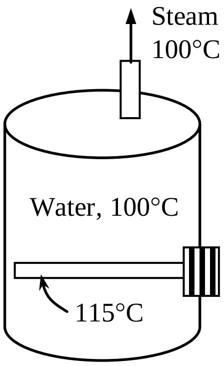
$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h^*_{fg}} = \frac{16{,}716{,}000 \text{ Btu/h}}{1051 \text{ Btu/lbm}} = \mathbf{15{,}900\ lbm/h}$$

10-77 Water is boiled at T_{sat} = 100°C by a chemically etched stainless steel electric heater whose surface temperature is maintained at T_s = 115°C. The rate of heat transfer to the water, the rate of evaporation of water, and the maximum rate of evaporation are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat losses from the heater and the boiler are negligible.

Properties The properties of water at the saturation temperature of 100°C are (Tables 10-1 and A-9)

$$\rho_l = 957.9 \text{ kg/m}^3 \qquad h_{fg} = 2257\times10^3 \text{ J/kg}$$
$$\rho_v = 0.60 \text{ kg/m}^3 \qquad \mu_l = 0.282\times10^{-3} \text{ kg}\cdot\text{m/s}$$
$$\sigma = 0.0589 \text{ N/m} \qquad C_{pl} = 4217 \text{ J/kg}\cdot°\text{C}$$
$$\text{Pr}_l = 1.75$$



Also, $C_{sf} = 0.0130$ and n = 1.0 for the boiling of water on a chemically etched stainless steel surface (Table 10-3). Note that we expressed the properties in units specified under Eq. 10-2 in connection with their definitions in order to avoid unit manipulations.

Analysis (*a*) The excess temperature in this case is $\Delta T = T_s - T_{\text{sat}} = 115 - 100 = 15°\text{C}$ which is relatively low (less than 30°C). Therefore, nucleate boiling will occur. The heat flux in this case can be determined from Rohsenow relation to be

$$\dot{q}_{\text{nucleate}} = \mu_l h_{fg}\left[\frac{g(\rho_l-\rho_v)}{\sigma}\right]^{1/2}\left(\frac{C_{p,l}(T_s-T_{\text{sat}})}{C_{sf}h_{fg}\,\text{Pr}_l^n}\right)^3$$
$$= (0.282\times10^{-3})(2257\times10^3)\left[\frac{9.8(957.9-0.60)}{0.0589}\right]^{1/2}\left(\frac{4217(115-100)}{0.0130(2257\times10^3)1.75}\right)^3$$
$$= 474{,}900 \text{ W/m}^2$$

The surface area of the bottom of the heater is $A_s = \pi DL = \pi(0.002\text{ m})(0.8\text{ m}) = 0.005027\text{ m}^2$.

Then the rate of heat transfer during nucleate boiling becomes

$$\dot{Q}_{\text{boiling}} = A_s\dot{q}_{\text{nucleate}} = (0.005027\text{ m}^2)(474{,}900\text{ W/m}^2) = \mathbf{2387\text{ W}}$$

The rate of evaporation of water is determined from

$$\dot{m}_{\text{evaporation}} = \frac{\dot{Q}_{\text{boiling}}}{h_{fg}} = \frac{2387\text{ J/s}}{2257\times10^3\text{ J/kg}} = \mathbf{1.058\times10^{-3}\text{ kg/s} = 3.81\text{ kg/h}}$$

(*b*) For a horizontal heating wire, the coefficient C_{cr} is determined from Table 10-4 to be

$$L^* = L\left(\frac{g(\rho_l-\rho_v)}{\sigma}\right)^{1/2} = (0.001)\left(\frac{9.8(957.9-0.60}{0.0589}\right)^{1/2} = 0.399 < 1.2$$
$$C_{cr} = 0.12L^{*-0.25} = 0.12(0.399)^{-0.25} = 0.151$$

Then the maximum or critical heat flux is determined from

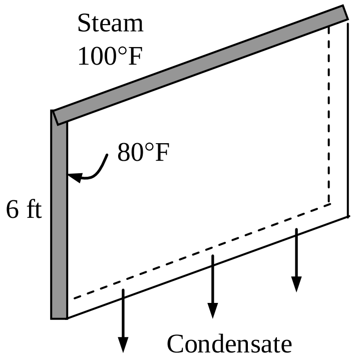
$$\dot{q}_{\max} = C_{cr}h_{fg}[\sigma g\rho_v^2(\rho_l-\rho_v)]^{1/4} = 0.151(2257\times10^3)[0.0589\times9.8\times(0.6)^2(957.9-0.60)]^{1/4}$$
$$= \mathbf{1{,}280{,}000\text{ W/m}^2}$$

10-78E Steam at a saturation temperature of T_{sat} = 100°F condenses on a vertical plate which is maintained at 80°C. The rate of heat transfer to the plate and the rate of condensation of steam per ft width of the plate are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The plate is isothermal. **3** The condensate flow is wavy-laminar over the entire plate (this assumption will be verified). **4** The density of vapor is much smaller than the density of liquid, $\rho_v << \rho_l$.

Properties The properties of water at the saturation temperature of 100°F are h_{fg} = 1037 Btu/lbm and ρ_v = 0.00286 lbm/ft^3. The properties of liquid water at the film temperature of $T_f = (T_{\text{sat}} + T_s)/2 = (100 + 80)/2 = 90$°F are (Table A-9E),

$$\rho_l = 62.12 \text{ lbm/ft}^3$$
$$\mu_l = 1.842 \text{ lbm/ft}\cdot\text{h}$$
$$\nu_l = \mu_l/\rho_l = 0.02965 \text{ ft}^2/\text{h}$$
$$C_{pl} = 0.999 \text{ Btu/lbm}\cdot{}^\circ\text{F}$$
$$k_l = 0.358 \text{ Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}$$



Analysis The modified latent heat of vaporization is

$$\begin{aligned} h^*_{fg} &= h_{fg} + 0.68C_{pl}(T_{\text{sat}} - T_s) \\ &= 1037 \text{ Btu/lbm} + 0.68 \times (0.999 \text{ Btu/lbm}\cdot{}^\circ\text{F})(100-80)^\circ\text{F} \\ &= 1051 \text{ Btu/lbm} \end{aligned}$$

Assuming wavy-laminar flow, the Reynolds number is determined from

$$\text{Re} = \text{Re}_{\text{vertical,wavy}} = \left[4.81 + \frac{3.70Lk_l(T_{\text{sat}} - T_s)}{\mu_l h^*_{fg}}\left(\frac{g}{\nu_l^2}\right)^{1/3}\right]^{0.820}$$

$$= \left[4.81 + \frac{3.70 \times (6 \text{ ft}) \times (0.358 \text{ Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}) \times (100-80)^\circ\text{F}}{(1.842 \text{ lbm/ft}\cdot\text{h})(1051 \text{ Btu/lbm})}\left(\frac{32.2 \text{ ft/s}^2}{(0.02965 \text{ ft}^2/\text{h})^2}\frac{(3600 \text{ s})^2}{(1 \text{ h})^2}\right)^{1/3}\right]^{0.82} = 201$$

which is between 30 and 1800, and thus our assumption of wavy laminar flow is verified. Then the condensation heat transfer coefficient is determined from

$$h = h_{\text{vertical,wavy}} = \frac{\text{Re}\, k_l}{1.08\,\text{Re}^{1.22} - 5.2}\left(\frac{g}{\nu_l^2}\right)^{1/3}$$

$$= \frac{201 \times (0.358 \text{ Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F})}{1.08(201)^{1.22} - 5.2}\left(\frac{32.2 \text{ ft/s}^2}{(0.02965 \text{ ft}^2/\text{h})^2}\frac{(3600 \text{ s})^2}{(1 \text{ h})^2}\right)^{1/3} = 813 \text{ Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$$

The heat transfer surface area of the plate is

$$A_s = W \times L = (6 \text{ ft})(1 \text{ ft}) = 6 \text{ ft}^2$$

Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA_s(T_{\text{sat}} - T_s) = (813 \text{ Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F})(6 \text{ ft}^2)(100-80)^\circ\text{F} = \mathbf{97{,}530 \text{ Btu/h}}$$

The rate of condensation of steam is determined from

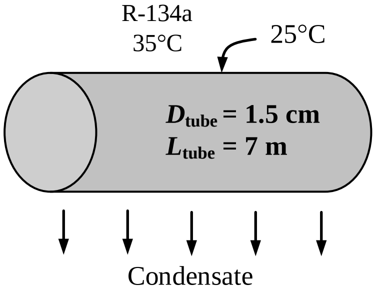
$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h^*_{fg}} = \frac{97{,}530 \text{ Btu/h}}{1051 \text{ Btu/lbm}} = \mathbf{92.8 \text{ lbm/h}}$$

10-79 Saturated refrigerant-134a vapor condenses on the outside of a horizontal tube maintained at a specified temperature. The rate of condensation of the refrigerant is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The tube is isothermal.

Properties The properties of refrigerant-134a at the saturation temperature of 35°C are $h_{fg} = 168.2\times10^3$ J/kg and $\rho_v = 43.41$ kg/m^3. The properties of liquid R-134a at the film temperature of $T_f = (T_{\text{sat}} + T_s)/2 = (35 + 25)/2 = 30$°C are (Table A-10),

$$\begin{aligned}
\rho_l &= 1188 \text{ kg/m}^3 \\
\mu_l &= 1.888\times10^{-4} \text{ kg/m.s} \\
\nu_l &= \mu_l/\rho_l = 0.1590\times10^{-6} \text{ m}^2\text{/s} \\
\text{C}_{pl} &= 1448 \text{ J/kg.°C} \\
k_l &= 0.0808 \text{ W/m.°C}
\end{aligned}$$



Analysis The modified latent heat of vaporization is

$$\begin{aligned}
h^*_{fg} &= h_{fg} + 0.68C_{pl}(T_{\text{sat}} - T_s) \\
&= 168.2\times10^3 \text{ J/kg} + 0.68\times1448 \text{ J/kg}\cdot\text{°C}(35-25)\text{°C} = 178.0\times10^3 \text{ J/kg}
\end{aligned}$$

The heat transfer coefficient for condensation on a single horizontal tube is

$$\begin{aligned}
h = h_{\text{horizontal}} &= 0.729\left[\frac{g\rho_l(\rho_l-\rho_v)h^*_{fg}k_l^3}{\mu_l(T_{\text{sat}}-T_s)D}\right]^{1/4} \\
&= 0.729\left[\frac{(9.81\text{ m/s}^2)(1188\text{ kg/m}^3)(1188-43.41\text{ kg/m}^3)(178.0\times10^3\text{ J/kg})(0.0808\text{ W/m}\cdot\text{°C})^3}{(1.888\times10^{-4}\text{ kg/m}\cdot\text{s})(35-25)\text{°C}(0.015\text{ m})}\right]^{1/4} \\
&= 1880 \text{ W/m}^2\cdot\text{°C}
\end{aligned}$$

The heat transfer surface area of the pipe is

$$A_s = \pi DL = \pi(0.015\text{ m})(7\text{ m}) = 0.3299\text{ m}^2$$

Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA_s(T_{\text{sat}} - T_s) = (1880\text{ W/m}^2\cdot\text{°C})(0.3299\text{ m}^2)(35-25)\text{°C} = 6200\text{ W}$$

The rate of condensation of steam is determined from

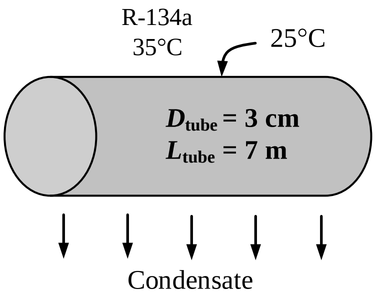
$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h^*_{fg}} = \frac{6200\text{ J/s}}{178.0\times10^3\text{ J/kg}} = 0.0348\text{ kg/s} = \mathbf{2.09\text{ kg/min}}$$

10-80 Saturated refrigerant-134a vapor condenses on the outside of a horizontal tube maintained at a specified temperature. The rate of condensation of the refrigerant is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The tube is isothermal.

Properties The properties of refrigerant-134a at the saturation temperature of 35°C are $h_{fg} = 168.2\times10^3$ J/kg and $\rho_v = 43.41$ kg/m^3. The properties of liquid R-134a at the film temperature of $T_f = (T_{sat} + T_s)/2 = (35 + 25)/2 = 30$°C are (Table A-10),

$$\rho_l = 1188\text{ kg/m}^3$$
$$\mu_l = 1.888\times10^{-4}\text{ kg/m.s}$$
$$\nu_l = \mu_l/\rho_l = 0.1590\times10^{-6}\text{ m}^2\text{/s}$$
$$C_{pl} = 1448\text{ J/kg.°C}$$
$$k_l = 0.0808\text{ W/m.°C}$$



Analysis The modified latent heat of vaporization is

$$h^*_{fg} = h_{fg} + 0.68C_{pl}(T_{sat} - T_s)$$
$$= 168.2\times10^3\text{ J/kg} + 0.68\times1448\text{ J/kg}\cdot\text{°C}(35-25)\text{°C} = 178.0\times10^3\text{ J/kg}$$

The heat transfer coefficient for condensation on a single horizontal tube is

$$h = h_{horizontal} = 0.729\left[\frac{g\rho_l(\rho_l - \rho_v)h^*_{fg}k_l^3}{\mu_l(T_{sat} - T_s)D}\right]^{1/4}$$
$$= 0.729\left[\frac{(9.81\text{ m/s}^2)(1188\text{ kg/m}^3)(1188-43.41\text{ kg/m}^3)(178.0\times10^3\text{ J/kg})(0.0808\text{ W/m}\cdot\text{°C})^3}{(1.888\times10^{-4}\text{ kg/m}\cdot\text{s})(35-25)\text{°C}(0.03\text{ m})}\right]^{1/4}$$
$$= 1581\text{ W/m}^2\cdot\text{°C}$$

The heat transfer surface area of the pipe is

$$A_s = \pi DL = \pi(0.03\text{ m})(7\text{ m}) = 0.6597\text{ m}^2$$

Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA_s(T_{sat} - T_s) = (1581\text{ W/m}^2\cdot\text{°C})(0.6597\text{ m}^2)(35-25)\text{°C} = 10{,}428\text{ W}$$

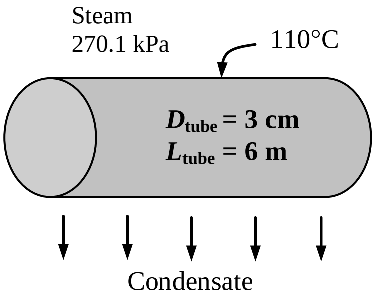
The rate of condensation of steam is determined from

$$\dot{m}_{condensation} = \frac{\dot{Q}}{h^*_{fg}} = \frac{10{,}428\text{ J/s}}{178.0\times10^3\text{ J/kg}} = 0.05858\text{ kg/s} = \mathbf{3.52\text{ kg/min}}$$

10-81 Saturated steam at 270 kPa pressure and thus at a saturation temperature of T_{sat} = 130°C (Table A-9) condenses inside a horizontal tube which is maintained at 110°C. The average heat transfer coefficient and the rate of condensation of steam are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The tube is isothermal. **3** The vapor velocity is low so that $\text{Re}_{\text{vapor}} < 35{,}000$.

Properties The properties of water at the saturation temperature of 130°C are $h_{fg} = 2174\times10^3$ J/kg and ρ_v = 1.50 kg/m^3. The properties of liquid water at the film temperature of $T_f = (T_{\text{sat}} + T_s)/2 = (130 + 110)/2$ = 120°C are (Table A-9),



$$\rho_l = 943.4 \text{ kg/m}^3$$
$$\mu_l = 0.232\times10^{-3}\text{ kg/m.s}$$
$$\nu_l = \mu_l/\rho_l = 0.246\times10^{-6}\text{ m}^2/\text{s}$$
$$\text{C}_{pl} = 4244 \text{ J/kg.°C}$$
$$k_l = 0.683 \text{ W/m.°C}$$

Analysis The condensation heat transfer coefficient is determined from

$$h = h_{\text{internal}} = 0.555\left[\frac{g\rho_l(\rho_l-\rho_v)k_l^3}{\mu_l(T_{\text{sat}}-T_s)}\left(h_{fg}+\frac{3}{8}C_{pl}(T_{\text{sat}}-T_s)\right)\right]^{1/4}$$
$$= 0.555\left[\frac{(9.8\text{ m/s}^2)(943.4\text{ kg/m}^3)(943.4-1.50)\text{ kg/m}^3)(0.683\text{ W/m}\cdot\text{°C})^3}{(0.232\times10^{-3}\text{ kg/m}\cdot\text{s})(130-110)\text{°C}}\right.$$
$$\left.\times\left(2174\times10^3\text{ J/kg}+\frac{3}{8}(4244\text{ kJ/kg}\cdot\text{°C})(130-110)\text{°C}\right)\right]^{1/4}$$
$$= \mathbf{3345\ W/m^2\cdot°C}$$

The heat transfer surface area of the pipe is

$$A_s = \pi DL = \pi(0.03\text{ m})(6\text{ m}) = 0.5655\text{ m}^2$$

Then the rate of heat transfer during this condensation process becomes

$$\dot{Q} = hA_s(T_{\text{sat}}-T_s) = (3345\text{ W/m}^2\cdot\text{°C})(0.5655\text{ m}^2)(130-110)\text{°C} = 37{,}831\text{ W}$$

The rate of condensation of steam is determined from

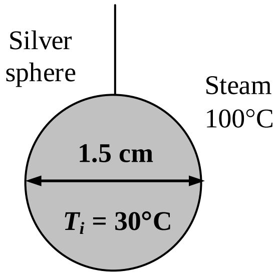
$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h_{fg}} = \frac{37{,}831\text{ J/s}}{2174\times10^3\text{ J/kg}} = \mathbf{0.0174\ kg/s}$$

10-82 Saturated steam condenses on a suspended silver sphere which is initially at 30°C. The time needed for the temperature of the sphere to rise to 50°C and the amount of steam condenses are to be determined.

Assumptions **1** The temperature of the sphere changes uniformly and thus the lumped system analysis is applicable. **2** The average condensation heat transfer coefficient evaluated for the average temperature can be used for the entire process. **3** Constant properties at room temperature can be used for the silver ball.

Properties The properties of water at the saturation temperature of 100°C are $h_{fg} = 2257\times10^3$ J/kg and $\rho_v = 0.60$ kg/m^3. The properties of the silver ball at room temperature and the properties of liquid water at the average film temperature of $T_f = (T_{\text{sat}} + T_{s,ave})/2 = (100 + 40)/2 = 70°\text{C}$ are (Tables A-3 and A-9),

Silver Ball:	**Liquid Water:**
$\rho = 10{,}500 \text{ kg/m}^3$	$\rho_l = 977.5 \text{ kg/m}^3$
$\alpha = 174\times10^{-6} \text{m}^2/\text{s}$	$\mu_l = 0.404\times10^{-3}\text{kg/m}\cdot\text{s}$
$\text{C}_p = 235 \text{ J/kg}\cdot°\text{C}$	$\text{C}_{pl} = 4190 \text{ J/kg}\cdot°\text{C}$
$k_l = 429 \text{ W/m}\cdot°\text{C}$	$k_l = 0.663 \text{ W/m}\cdot°\text{C}$



Analysis The modified latent heat of vaporization is

$$\begin{aligned} h^*_{fg} &= h_{fg} + 0.68C_{pl}(T_{\text{sat}} - T_s) \\ &= 2257\times10^3 \text{ J/kg} + 0.68\times4190 \text{ J/kg}\cdot°\text{C}(100-40)°\text{C} = 2428\times10^3 \text{ J/kg} \end{aligned}$$

Noting that the tube is horizontal, the condensation heat transfer coefficient is determined from

$$\begin{aligned} h = h_{\text{sph}} &= 0.813\left[\frac{g\rho_l(\rho_l-\rho_v)h^*_{fg}k_l^3}{\mu_l(T_{\text{sat}}-T_s)D}\right]^{1/4} \\ &= 0.813\left[\frac{(9.8 \text{ m/s}^2)(977.5 \text{ kg/m}^3)(977.5-0.60 \text{ kg/m}^3)(2428\times10^3 \text{ J/kg})(0.663 \text{ W/m}\cdot°\text{C})^3}{(0.404\times10^{-3} \text{ kg/m}\cdot\text{s})(100-40)°\text{C}(0.015 \text{ m})}\right]^{1/4} \\ &= 9445 \text{ W/m}^2\cdot°\text{C} \end{aligned}$$

The characteristic length and the Biot number for the lumped system analysis is (see Chap. 4)

$$L_c = \frac{V}{A} = \frac{\pi D^3/6}{\pi D^2} = \frac{D}{6} = \frac{0.015 \text{ m}}{6} = 0.0025 \text{ m}$$

$$Bi = \frac{hL_c}{k} = \frac{(9445 \text{ W/m}^2\cdot°\text{C})(0.0025 \text{ m})}{(429 \text{ W/m}\cdot°\text{C})} = 0.055 \; < 0.1$$

The lumped system analysis is applicable since Bi < 0.1. Then the time needed for the temperature of the sphere to rise from 30 to 50°C is determined to be

$$b = \frac{hA_s}{\rho C_p V} = \frac{h}{\rho C_p L_c} = \frac{9445 \text{ W/m}^2\cdot°\text{C}}{(10{,}500 \text{ kg/m}^3)(235 \text{ J/kg}\cdot°\text{C})(0.0025 \text{ m})} = 1.531 \text{s}^{-1}$$

$$\frac{T(t)-T_\infty}{T_i - T_\infty} = e^{-bt} \longrightarrow \frac{50-100}{30-100} = e^{-1.531t} \longrightarrow t = \mathbf{0.22\,s}$$

The total heat transfer to the ball and the amount of steam that condenses become

$$m_{\text{sphere}} = \rho V = \rho\frac{\pi D^3}{6} = (10{,}500 \text{ kg/m}^3)\frac{\pi(0.015 \text{ m})^3}{6} = 0.0186 \text{ kg}$$

$$Q = mC_p[T(t) - T_i]_{\text{sphere}} = (0.0186 \text{ kg})(235 \text{ J/kg}\cdot°\text{C})(50-30)°\text{C} = 87.2 \text{ J}$$

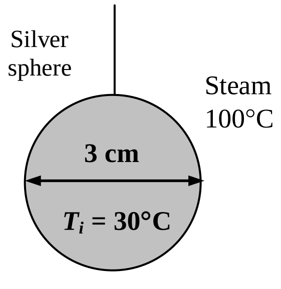
$$\dot{m}_{\text{condensation}} = \frac{\dot{Q}}{h^*_{fg}} = \frac{87.2 \text{ J/s}}{2428\times10^3 \text{ J/kg}} = \mathbf{0.0359\times10^{-3}\ kg/s}$$

10-83 Steam at a saturation temperature of T_{sat} = 100°C condenses on a suspended silver sphere which is initially at 30°C. The time needed for the temperature of the sphere to rise to 50°C and the amount of steam condenses during this process are to be determined.

Assumptions **1** The temperature of the sphere changes uniformly and thus the lumped system analysis is applicable. **2** The average condensation heat transfer coefficient evaluated for the average temperature can be used for the entire process. **3** Constant properties at room temperature can be used for the silver ball.

Properties The properties of water at the saturation temperature of 100°C are $h_{\mathrm{fg}} = 2257\times10^3$ J/kg and ρ_v = 0.60 kg/m^3. The properties of the silver ball at room temperature and the properties of liquid water at the average film temperature of $T_f = (T_{\mathrm{sat}} + T_{s,ave})/2 = (100 + 40)/2 = 70°\mathrm{C}$ are (Tables A-3 and A-9),

Silver Ball:	**Liquid Water:**
$\rho = 10{,}500\ \mathrm{kg/m^3}$	$\rho_l = 977.5\ \mathrm{kg/m^3}$
$\alpha = 174\times10^{-6}\ \mathrm{m^2/s}$	$\mu_l = 0.404\times10^{-3}\ \mathrm{kg/m\cdot s}$
$C_p = 235\ \mathrm{J/kg\cdot°C}$	$C_{pl} = 4190\ \mathrm{J/kg\cdot°C}$
$k_l = 429\ \mathrm{W/m\cdot°C}$	$k_l = 0.663\ \mathrm{W/m\cdot°C}$



Analysis The modified latent heat of vaporization is

$$h^*_{fg} = h_{fg} + 0.68C_{pl}(T_{\mathrm{sat}} - T_s)$$
$$= 2257\times10^3\ \mathrm{J/kg} + 0.68\times4190\ \mathrm{J/kg\cdot°C}(100-40)°\mathrm{C} = 2428\times10^3\ \mathrm{J/kg}$$

Noting that the tube is horizontal, the condensation heat transfer coefficient is determined from

$$h = h_{\mathrm{sph}} = 0.813\left[\frac{g\rho_l(\rho_l-\rho_v)h^*_{fg}k_l^3}{\mu_l(T_{\mathrm{sat}}-T_s)D}\right]^{1/4}$$
$$= 0.813\left[\frac{(9.8\ \mathrm{m/s^2})(977.5\ \mathrm{kg/m^3})(977.5-0.60\ \mathrm{kg/m^3})(2428\times10^3\ \mathrm{J/kg})(0.663\ \mathrm{W/m\cdot°C})^3}{(0.404\times10^{-3}\ \mathrm{kg/m\cdot s})(100-40)°\mathrm{C}(0.03\ \mathrm{m})}\right]^{1/4}$$
$$= 7942\ \mathrm{W/m^2\cdot°C}$$

The characteristic length and the Biot number for the lumped system analysis is (see Chap. 4)

$$L_c = \frac{V}{A_s} = \frac{\pi D^3/6}{\pi D^2} = \frac{D}{6} = \frac{0.03\ \mathrm{m}}{6} = 0.005\ \mathrm{m}$$
$$Bi = \frac{hL_c}{k} = \frac{(7942\ \mathrm{W/m^2\cdot°C})(0.005\ \mathrm{m})}{(429\ \mathrm{W/m\cdot°C})} = 0.093 < 0.1$$

The lumped system analysis is applicable since Bi < 0.1. Then the time needed for the temperature of the sphere to rise from 30 to 50°C is determined to be

$$b = \frac{hA_s}{\rho C_p V} = \frac{h}{\rho C_p L_c} = \frac{7942\ \mathrm{W/m^2\cdot°C}}{(10{,}500\ \mathrm{kg/m^3})(235\ \mathrm{J/kg\cdot°C})(0.005\ \mathrm{m})} = 0.644\ \mathrm{s^{-1}}$$
$$\frac{T(t)-T_\infty}{T_i - T_\infty} = e^{-bt} \longrightarrow \frac{50-100}{30-100} = e^{-0.644t} \longrightarrow t = \mathbf{0.52\ s}$$

The total heat transfer to the ball and the amount of steam that condenses become

$$m_{\mathrm{sphere}} = \rho V = \rho\frac{\pi D^3}{6} = (10{,}500\ \mathrm{kg/m^3})\frac{\pi(0.03\ \mathrm{m})^3}{6} = 0.148\ \mathrm{kg}$$
$$Q = mC_p[T(t) - T_i]_{\mathrm{sphere}} = (0.148\ \mathrm{kg})(235\ \mathrm{J/kg\cdot°C})(50-30)°\mathrm{C} = 698\ \mathrm{J}$$
$$\dot{m}_{\mathrm{condensation}} = \frac{\dot{Q}}{h^*_{fg}} = \frac{698\ \mathrm{J/s}}{2428\times10^3\ \mathrm{J/kg}} = \mathbf{0.287\times10^{-3}\ kg/s}$$

10-84 Saturated steam at a saturation temperature of T_{sat} = 95°C (Table A-9) condenses on a canned drink at 5°C in a dropwise manner. The heat transfer coefficient for this dropwise condensation is to be determined.

Steam
95°C
Drink
5°C

Assumptions The heat transfer coefficient relation for dropwise condensation that was developed for copper surfaces is also applicable for aluminum surfaces.

Analysis Noting that the saturation temperature is less than 100°C, the heat transfer coefficient for dropwise condensation can be determined from Griffith's relation to be

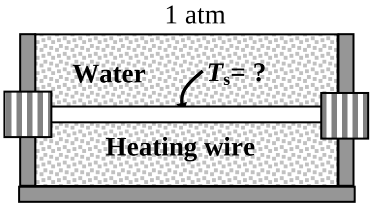
$$h = h_{\text{dropwise}} = 51{,}104 + 2044T_{\text{sat}} = 51{,}104 + 2044 \times 95 = \mathbf{245{,}284\ W/m^2{\cdot}°C}$$

10-85 Water is boiled at 1 atm pressure and thus at a saturation temperature of T_{sat} = 100°C by a nickel electric heater whose diameter is 2 mm. The highest temperature at which this heater can operate without burnout is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat losses from the water are negligible.

Properties The properties of water at the saturation temperature of 100°C are (Tables 10-1 and A-9)

$\rho_l = 957.9\ \text{kg/m}^3$
$\rho_v = 0.60\ \text{kg/m}^3$
$\sigma = 0.0589\ \text{N/m}$
$\text{Pr}_l = 1.75$
$h_{fg} = 2257 \times 10^3\ \text{J/kg}$
$\mu_l = 0.282 \times 10^{-3}\ \text{kg}\cdot\text{m/s}$
$C_{pl} = 4217\ \text{J/kg}\cdot°\text{C}$



Also, $C_{sf} = 0.0060$ and n = 1.0 for the boiling of water on a nickel surface (Table 10-3).

Analysis The maximum rate of heat transfer without the burnout is simply the critical heat flux. For a horizontal heating wire, the coefficient C_{cr} is determined from Table 10-4 to be

$$L^* = L\left(\frac{g(\rho_l - \rho_v)}{\sigma}\right)^{1/2} = (0.001)\left(\frac{9.8(957.9 - 0.60}{0.0589}\right)^{1/2} = 0.399 < 1.2$$

$$C_{cr} = 0.12L^{*-0.25} = 0.12(0.399)^{-0.25} = 0.151$$

Then the maximum or critical heat flux is determined from

$$\dot{q}_{\max} = C_{cr}h_{fg}[\sigma g\rho_v^2(\rho_l - \rho_v)]^{1/4} = 0.151(2257 \times 10^3)[0.0589 \times 9.8 \times (0.6)^2(957.9 - 0.60)]^{1/4}$$
$$= 1{,}280{,}000\ \text{W/m}^2$$

Rohsenow relation which gives the nucleate boiling heat flux for a specified surface temperature can also be used to determine the surface temperature when the heat flux is given. Substituting the maximum heat flux into Rohsenow relation together with other properties gives

$$\dot{q}_{\text{nucleate}} = \mu_l h_{fg}\left[\frac{g(\rho_l - \rho_v)}{\sigma}\right]^{1/2}\left(\frac{C_{p,l}(T_s - T_{\text{sat}})}{C_{sf}h_{fg}\,\text{Pr}_l^n}\right)^3$$

$$1{,}280{,}000 = (0.282 \times 10^{-3})(2257 \times 10^3)\left[\frac{9.8(957.9\text{ - }0.60)}{0.0589}\right]^{1/2}\left(\frac{4217(T_s - 100)}{0.0060(2257 \times 10^3)1.75}\right)^3$$

It gives the maximum temperature to be: $T_s = \mathbf{109.6°C}$

10-86 ... 10-93 Design and Essay Problems

Chapter 11

FUNDAMENTALS OF THERMAL RADIATION

Electromagnetic and Thermal Radiation

11-1C Electromagnetic waves are caused by accelerated charges or changing electric currents giving rise to electric and magnetic fields. Sound waves are caused by disturbances. Electromagnetic waves can travel in vacuum, sound waves cannot.

11-2C Electromagnetic waves are characterized by their frequency v and wavelength λ. These two properties in a medium are related by $\lambda = c/v$ where c is the speed of light in that medium.

11-3C Visible light is a kind of electromagnetic wave whose wavelength is between 0.40 and 0.76 μm. It differs from the other forms of electromagnetic radiation in that it triggers the sensation of seeing in the human eye.

11-4C Infrared radiation lies between 0.76 and 100 μm whereas ultraviolet radiation lies between the wavelengths 0.01 and 0.40 μm. The human body does not emit any radiation in the ultraviolet region since bodies at room temperature emit radiation in the infrared region only.

11-5C Thermal radiation is the radiation emitted as a result of vibrational and rotational motions of molecules, atoms and electrons of a substance, and it extends from about 0.1 to 100 μm in wavelength. Unlike the other forms of electromagnetic radiation, thermal radiation is emitted by bodies because of their temperature.

11-6C Light (or visible) radiation consists of narrow bands of colors from violet to red. The color of a surface depends on its ability to reflect certain wavelength. For example, a surface that reflects radiation in the wavelength range 0.63-0.76 μm while absorbing the rest appears red to the eye. A surface that reflects all the light appears white while a surface that absorbs the entire light incident on it appears black. The color of a surface at room temperature is not related to the radiation it emits.

11-7C Radiation in opaque solids is considered surface phenomena since only radiation emitted by the molecules in a very thin layer of a body at the surface can escape the solid.

11-8C Because the snow reflects almost all of the visible and ultraviolet radiation, and the skin is exposed to radiation both from the sun and from the snow.

11-9C Microwaves in the range of 10^2 to 10^5 μm are very suitable for use in cooking as they are reflected by metals, transmitted by glass and plastics and absorbed by food (especially water) molecules. Thus the electric energy converted to radiation in a microwave oven eventually becomes part of the internal energy of the food with no conduction and convection thermal resistances involved. In conventional cooking, on the other hand, conduction and convection thermal resistances slow down the heat transfer, and thus the heating process.

11-10 Electricity is generated and transmitted in power lines at a frequency of 60 Hz. The wavelength of the electromagnetic waves is to be determined.

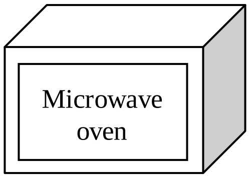
Analysis The wavelength of the electromagnetic waves is

$$\lambda = \frac{c}{v} = \frac{2.998\times10^8 \text{ m/s}}{60 \text{ Hz}(1/\text{s})} = \mathbf{4.997\times10^6 \text{ m}}$$

Power lines

11-11 A microwave oven operates at a frequency of 2.8×10^9 Hz. The wavelength of these microwaves and the energy of each microwave are to be determined.

Analysis The wavelength of these microwaves is



$$\lambda = \frac{c}{v} = \frac{2.998\times10^8 \text{ m/s}}{2.8\times10^9 \text{ Hz}(1/\text{s})} = 0.107 \text{ m} = \mathbf{107 \text{ mm}}$$

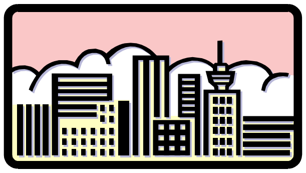
Then the energy of each microwave becomes

$$e = hv = \frac{hc}{\lambda} = \frac{(6.625\times10^{-34} \text{ Js})(2.998\times10^8 \text{ m/s})}{0.107 \text{ m}} = \mathbf{1.86\times10^{-24} \text{ J}}$$

11-12 A radio station is broadcasting radiowaves at a wavelength of 200 m. The frequency of these waves is to be determined.

Analysis The frequency of the waves is determined from

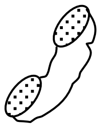
$$\lambda = \frac{c}{v} \longrightarrow v = \frac{c}{\lambda} = \frac{2.998\times10^8 \text{ m/s}}{200 \text{ m}} = \mathbf{1.5\times10^6 \text{ Hz}}$$



11-13 A cordless telephone operates at a frequency of 8.5×10^8 Hz. The wavelength of these telephone waves is to be determined.

Analysis The wavelength of the telephone waves is

$$\lambda = \frac{c}{v} = \frac{2.998\times10^8 \text{ m/s}}{8.5\times10^8 \text{ Hz}(1/\text{s})} = 0.35 \text{ m} = \mathbf{350 \text{ mm}}$$



Blackbody Radiation

11-14C A blackbody is a perfect emitter and absorber of radiation. A blackbody does not actually exist. It is an idealized body that emits the maximum amount of radiation that can be emitted by a surface at a given temperature.

11-15C *Spectral blackbody emissive power* is the amount of radiation energy emitted by a blackbody at an absolute temperature T per unit time, per unit surface area and per unit wavelength about wavelength λ. The integration of the spectral blackbody emissive power over the entire wavelength spectrum gives the *total blackbody emissive power*,

$$E_b(T) = \int_0^\infty E_{b\lambda}(T)d\lambda = \sigma T^4$$

The spectral blackbody emissive power varies with wavelength, the total blackbody emissive power does not.

11-16C We defined the blackbody radiation function f_λ because the integration $\int_0^\infty E_{b\lambda}(T)d\lambda$ cannot be performed. The blackbody radiation function f_λ represents the fraction of radiation emitted from a blackbody at temperature *T* in the wavelength range from $\lambda = 0$ to λ. This function is used to determine the fraction of radiation in a wavelength range between λ_1 and λ_2.

11-17C The larger the temperature of a body , the larger the fraction of the radiation emitted in shorter wavelengths. Therefore, the body at 1500 K will emit more radiation in the shorter wavelength region. The body at 1000 K emits more radiation at $20\ \mu m$ than the body at 1500 K since $\lambda T = \text{constant}$.

11-18 An isothermal cubical body is suspended in the air. The rate at which the cube emits radiation energy and the spectral blackbody emissive power are to be determined.

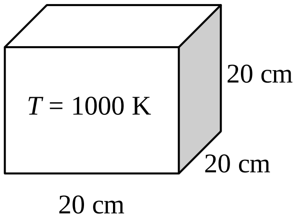
Assumptions The body behaves as a black body.

Analysis (*a*) The total blackbody emissive power is determined from Stefan-Boltzman Law to be

$$A_s = 6a^2 = 6(0.2^2) = 0.24\ \text{m}^2$$

$$E_b(T) = \sigma T^4 A_s = (5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)(1000\ \text{K})^4(0.24\ \text{m}^2) = \mathbf{1.36\times10^4\ W}$$

(*b*) The spectral blackbody emissive power at a wavelength of 4 μ*m* is determined from Plank's distribution law,



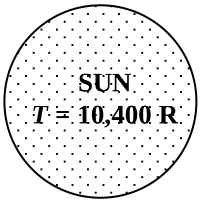
$$E_{b\lambda} = \frac{C_1}{\lambda^5\left[\exp\left(\dfrac{C_2}{\lambda T}\right)-1\right]} = \frac{3.743\times10^8\ \text{W}\cdot\mu\text{m}^4/\text{m}^2}{(4\ \mu\text{m})^5\left[\exp\left(\dfrac{1.4387\times10^4\ \mu\text{m}\cdot\text{K}}{(4\ \mu\text{m})(1000\ \text{K})}\right)-1\right]}$$

$$= \mathbf{10.3\ kW/m^2\cdot\mu m}$$

11-19E The sun is at an effective surface temperature of 10,372 R. The rate of infrared radiation energy emitted by the sun is to be determined.

Assumptions The sun behaves as a black body.

Analysis Noting that *T* = 10,400 R = 5778 K, the blackbody radiation functions corresponding to $\lambda_1 T$ and $\lambda_2 T$ are determined from Table 11-2 to be



$$\lambda_1 T = (0.76\ \mu\text{m})(5778\ \text{K}) = 4391.3\ \mu\text{mK} \longrightarrow \text{f}_{\lambda_1} = 0.547370$$

$$\lambda_2 T = (100\ \mu\text{m})(5778\ \text{K}) = 577{,}800\ \mu\text{mK} \longrightarrow \text{f}_{\lambda_2} = 1.0$$

Then the fraction of radiation emitted between these two wavelengths becomes

$$f_{\lambda_2} - f_{\lambda_1} = 1.0 - 0.547 = 0.453 \qquad \text{(or 45.3\%)}$$

The total blackbody emissive power of the sun is determined from Stefan-Boltzman Law to be

$$E_b = \sigma T^4 = (0.1714\times10^{-8}\ \text{Btu/h.ft}^2.\text{R}^4)(10{,}400\ \text{R})^4 = 2.005\times10^7\ \text{Btu/h.ft}^2$$

Then,

$$E_{\text{infrared}} = (0.451)E_b = (0.453)(2.005\times10^7\ \text{Btu/h.ft}^2) = \mathbf{9.08\times10^6\ Btu/h.ft^2}$$

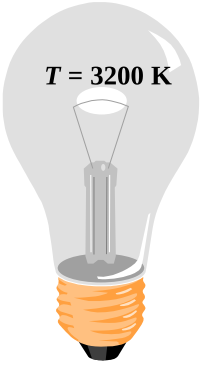
11-21 The temperature of the filament of an incandescent light bulb is given. The fraction of visible radiation emitted by the filament and the wavelength at which the emission peaks are to be determined.

Assumptions The filament behaves as a black body.

Analysis The visible range of the electromagnetic spectrum extends from $\lambda_1 = 0.40\ \mu\text{m}$ to $\lambda_2 = 0.76\ \mu\text{m}$. Noting that $T = 3200$ K, the blackbody radiation functions corresponding to $\lambda_1 T$ and $\lambda_2 T$ are determined from Table 11-2 to be



$$\lambda_1 T = (0.40\ \mu\text{m})(3200\ \text{K}) = 1280\ \mu\text{mK} \longrightarrow \text{f}_{\lambda_1} = 0.0043964$$

$$\lambda_2 T = (0.76\ \mu\text{m})(3200\ \text{K}) = 2432\ \mu\text{mK} \longrightarrow \text{f}_{\lambda_2} = 0.147114$$

Then the fraction of radiation emitted between these two wavelengths becomes

$$f_{\lambda_2} - f_{\lambda_1} = 0.14711424 - 0.0043964 = \mathbf{0.142718} \qquad \text{(or 14.3\%)}$$

The wavelength at which the emission of radiation from the filament is maximum is

$$(\lambda T)_{\text{max power}} = 2897.8\ \mu\text{m}\cdot\text{K} \longrightarrow \lambda_{\text{max power}} = \frac{2897.8\ \mu\text{m}\cdot\text{K}}{3200\ \text{K}} = \mathbf{0.905\ mm}$$

11-23 An incandescent light bulb emits 15% of its energy at wavelengths shorter than 1 μm. The temperature of the filament is to be determined.

Assumptions The filament behaves as a black body.

Analysis From the Table 11-2 for the fraction of the radiation, we read

$$f_\lambda = 0.15 \longrightarrow \lambda T = 2445\ \mu\text{mK}$$

For the wavelength range of $\lambda_1 = 0.0$ μm to $\lambda_2 = 1.0$ μm

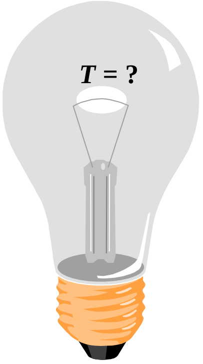
$$\lambda = 1\ \mu\text{m} \longrightarrow \lambda T = 2445\ \mu\text{mK} \longrightarrow T = \mathbf{2445\ K}$$

11-24 Radiation emitted by a light source is maximum in the blue range. The temperature of this light source and the fraction of radiation it emits in the visible range are to be determined.

Assumptions The light source behaves as a black body.

Analysis The temperature of this light source is

$$(\lambda T)_{\text{max power}} = 2897.8\ \mu\text{m}\cdot\text{K} \longrightarrow T = \frac{2897.8\ \mu\text{m}\cdot\text{K}}{0.47\ \mu\text{m}} = \mathbf{6166\ K}$$



The visible range of the electromagnetic spectrum extends from $\lambda_1 = 0.40\ \mu\text{m}$ to $\lambda_2 = 0.76\ \mu\text{m}$. Noting that T = 6166 K, the blackbody radiation functions corresponding to $\lambda_1 T$ and $\lambda_2 T$ are determined from Table 11-2 to be

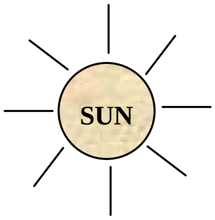
$$\lambda_1 T = (0.40\ \mu\text{m})(6166\ \text{K}) = 2466\ \mu\text{mK} \longrightarrow \text{f}_{\lambda_1} = 0.15444$$

$$\lambda_2 T = (0.76\ \mu\text{m})(6166\ \text{K}) = 4686\ \mu\text{mK} \longrightarrow \text{f}_{\lambda_2} = 0.59141$$

Then the fraction of radiation emitted between these two wavelengths becomes

$$f_{\lambda_2} - f_{\lambda_1} = 0.59141 - 0.15444 \cong \mathbf{0.437} \qquad \text{(or 43.7\%)}$$

11-25 A glass window transmits 90% of the radiation in a specified wavelength range and is opaque for radiation at other wavelengths. The rate of radiation transmitted through this window is to be determined for two cases.



Assumptions The sources behave as a black body.

Analysis The surface area of the glass window is

$$A_s = 4\ \text{m}^2$$

(*a*) For a blackbody source at 5800 K, the total blackbody radiation emission is

$$E_b(T) = \sigma T^4 A_s = (5.67\times10^{-8}\ \text{kW/m}^2.\text{K})^4(5800\ \text{K})^4(4\ \text{m}^2) = 2.567\times10^5\ \text{kW}$$

The fraction of radiation in the range of 0.3 to 3.0 μm is

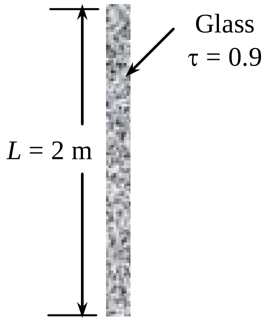
$$\lambda_1 T = (0.30\ \mu\text{m})(5800\ \text{K}) = 1740\ \mu\text{mK} \longrightarrow \text{f}_{\lambda_1} = 0.03345$$

$$\lambda_2 T = (3.0\ \mu\text{m})(5800\ \text{K}) = 17{,}400\ \mu\text{mK} \longrightarrow \text{f}_{\lambda_2} = 0.97875$$

$$\Delta f = f_{\lambda_2} - f_{\lambda_1} = 0.97875 - 0.03345 = 0.9453$$

Noting that 90% of the total radiation is transmitted through the window,

$$E_{\text{transmit}} = 0.90\Delta f E_b(T)$$
$$= (0.90)(0.9453)(2.567\times10^5\ \text{kW}) = \mathbf{2.184\times10^5\ kW}$$



(*b*) For a blackbody source at 1000 K, the total blackbody emissive power is

$$E_b(T) = \sigma T^4 A_s = (5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)(1000\ \text{K})^4(4\ \text{m}^2) = 226.8\ \text{kW}$$

The fraction of radiation in the visible range of 0.3 to 3.0 μm is

$$\lambda_1 T = (0.30\ \mu\text{m})(1000\ \text{K}) = 300\ \mu\text{mK} \longrightarrow f_{\lambda_1} = 0.0000$$

$$\lambda_2 T = (3.0\ \mu\text{m})(1000\ \text{K}) = 3000\ \mu\text{mK} \longrightarrow f_{\lambda_2} = 0.273232$$

$$\Delta f = f_{\lambda_2} - f_{\lambda_1} = 0.273232 - 0$$

and

$$E_{\text{transmit}} = 0.90\Delta f E_b(T) = (0.90)(0.273232)(226.8\ \text{kW}) = \mathbf{55.8\ kW}$$

Radiation Intensity

11-26C A solid angle represents an opening in space, whereas a plain angle represents an opening in a plane. For a sphere of unit radius, the solid angle about the origin subtended by a given surface on the sphere is equal to the area of the surface. For a cicle of unit radius, the plain angle about the origin subtended by a given arc is equal to the length of the arc. The value of a solid angle associated with a sphere is 4π.

11-27C The intensity of emitted radiation $I_e(\theta, \phi)$ is defined as the rate at which radiation energy $d\dot{Q}_e$ is emitted in the (θ, ϕ) direction per unit area normal to this direction and per unit solid angle about this direction. For a diffusely emitting surface, the emissive power is related to the intensity of emitted radiation by $E = \pi I_e$ (or $E_\lambda = \pi I_{\lambda,e}$ for spectral quantities).

11-28C Irradiation *G* is the radiation flux incident on a surface from all directions. For diffusely incident radiation, irradiation on a surface is related to the intensity of incident radiation by $G = \pi I_i$ (or $G_\lambda = \pi I_{\lambda,i}$ for spectral quantities).

11-29C Radiosity *J* is the rate at which radiation energy leaves a unit area of a surface by emission and reflection in all directions.. For a diffusely emitting and reflecting surface, radiosity is related to the intensity of emitted and reflected radiation by $J = \pi I_{e+r}$ (or $J_\lambda = \pi I_{\lambda,e+r}$ for spectral quantities).

11-30C When the variation of a spectral radiation quantity with wavelength is known, the correcponding total quantity is determined by integrating that quantity with respect to wavelength from λ = 0 to λ = ∞.

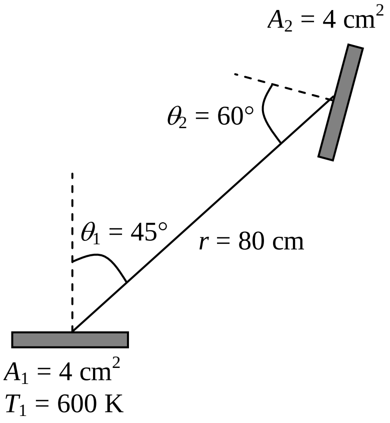
11-31 A surface is subjected to radiation emitted by another surface. The solid angle subtended and the rate at which emitted radiation is received are to be determined.

Assumptions **1** Surface A_1 emits diffusely as a blackbody. **2** Both A_1 and A_2 can be approximated as differential surfaces since both are very small compared to the square of the distance between them.

Analysis Approximating both A_1 and A_2 as differential surfaces, the solid angle subtended by A_2 when viewed from A_1 can be determined from Eq. 11-12 to be

$$\omega_{2-1} \cong \frac{A_{n,2}}{r^2} = \frac{A_2 \cos\theta_2}{r^2} = \frac{(4\,\text{cm}^2)\cos 60°}{(80\,\text{cm})^2} = \mathbf{3.125\times 10^{-4}\ sr}$$

since the normal of A_2 makes 60° with the direction of viewing. Note that solid angle subtended by A_2 would be maximum if A_2 were positioned normal to the direction of viewing. Also, the point of viewing on A_1 is taken to be a point in the middle, but it can be any point since A_1 is assumed to be very small.



The radiation emitted by A_1 that strikes A_2 is equivalent to the radiation emitted by A_1 through the solid angle ω_{2-1}. The intensity of the radiation emitted by A_1 is

$$I_1 = \frac{E_b(T_1)}{\pi} = \frac{\sigma T_1^4}{\pi} = \frac{(5.67\times 10^{-8}\ \text{W/m}^2\cdot\text{K}^4)(800\,\text{K})^4}{\pi} = 7393\,\text{W/m}^2\cdot\text{sr}$$

This value of intensity is the same in all directions since a blackbody is a diffuse emitter. Intensity represents the rate of radiation emission per unit area normal to the direction of emission per unit solid angle. Therefore, the rate of radiation energy emitted by A_1 in the direction of θ_1 through the solid angle ω_{2-1} is determined by multiplying I_1 by the area of A_1 normal to θ_1 and the solid angle ω_{2-1}. That is,

$$\begin{aligned}\dot{Q}_{1-2} &= I_1(A_1\cos\theta_1)\omega_{2-1}\\ &= (7393\,\text{W/m}^2\cdot\text{sr})(4\times 10^{-4}\cos 45°\,\text{m}^2)(3.125\times 10^{-4}\ \text{sr})\\ &= \mathbf{6.534\times 10^{-4}\ W}\end{aligned}$$

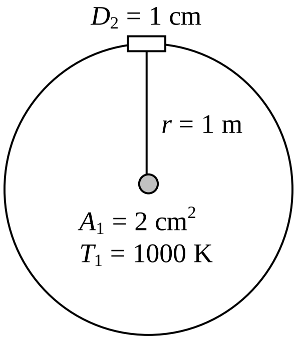
Therefore, the radiation emitted from surface A_1 will strike surface A_2 at a rate of 6.534×10^{-4} W.

If A_2 were directly above A_1 at a distance 80 cm, θ_1 = 0° and the rate of radiation energy emitted by A_1 becomes zero.

11-32 Radiation is emitted from a small circular surface located at the center of a sphere. Radiation energy streaming through a hole located on top of the sphere and the side of sphere are to be determined.

Assumptions **1** Surface A_1 emits diffusely as a blackbody. **2** Both A_1 and A_2 can be approximated as differential surfaces since both are very small compared to the square of the distance between them.

Analysis (*a*) Approximating both A_1 and A_2 as differential surfaces, the solid angle subtended by A_2 when viewed from A_1 can be determined from Eq. 11-12 to be



$$\omega_{2-1} \cong \frac{A_{n,2}}{r^2} = \frac{A_2}{r^2} = \frac{\pi(0.005\,\text{m})^2}{(1\,\text{m})^2} = 7.854\times10^{-5}\text{ sr}$$

since A_2 were positioned normal to the direction of viewing.

The radiation emitted by A_1 that strikes A_2 is equivalent to the radiation emitted by A_1 through the solid angle $\omega_{2\text{-}1}$. The intensity of the radiation emitted by A_1 is

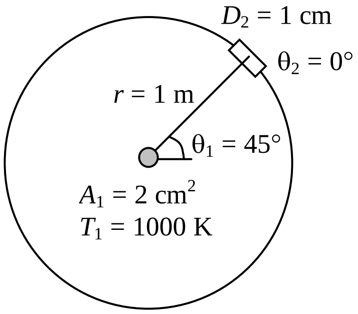
$$I_1 = \frac{E_b(T_1)}{\pi} = \frac{\sigma T_1^4}{\pi} = \frac{(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)(1000\text{ K})^4}{\pi} = 18{,}048\text{ W/m}^2\cdot\text{sr}$$

This value of intensity is the same in all directions since a blackbody is a diffuse emitter. Intensity represents the rate of radiation emission per unit area normal to the direction of emission per unit solid angle. Therefore, the rate of radiation energy emitted by A_1 in the direction of θ_1 through the solid angle $\omega_{2\text{-}1}$ is determined by multiplying I_1 by the area of A_1 normal to θ_1 and the solid angle $\omega_{2\text{-}1}$. That is,

$$\begin{aligned}\dot{Q}_{1-2} &= I_1(A_1\cos\theta_1)\omega_{2-1}\\ &= (18{,}048\text{ W/m}^2\cdot\text{sr})(2\times10^{-4}\cos0^\circ\text{ m}^2)(7.854\times10^{-5}\text{ sr})\\ &= \mathbf{2.835\times10^{-4}\ W}\end{aligned}$$

where θ_1 = 0°. Therefore, the radiation emitted from surface A_1 will strike surface A_2 at a rate of 2.835×10^{-4} W.

(*b*) In this orientation, θ_1 = 45° and θ_2 = 0°. Repeating the calculation we obtain the rate of radiation to be

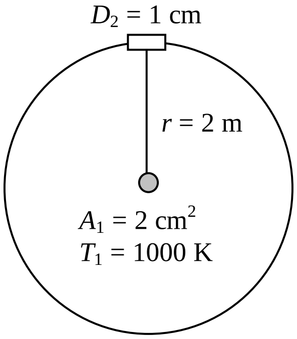


$$\begin{aligned}\dot{Q}_{1-2} &= I_1(A_1\cos\theta_1)\omega_{2-1}\\ &= (18{,}048\text{ W/m}^2\cdot\text{sr})(2\times10^{-4}\cos45^\circ\text{ m}^2)(7.854\times10^{-5}\text{ sr})\\ &= \mathbf{2.005\times10^{-4}\ W}\end{aligned}$$

11-33 Radiation is emitted from a small circular surface located at the center of a sphere. Radiation energy streaming through a hole located on top of the sphere and the side of sphere are to be determined.

Assumptions **1** Surface A_1 emits diffusely as a blackbody. **2** Both A_1 and A_2 can be approximated as differential surfaces since both are very small compared to the square of the distance between them.

Analysis (*a*) Approximating both A_1 and A_2 as differential surfaces, the solid angle subtended by A_2 when viewed from A_1 can be determined from Eq. 11-12 to be



$$\omega_{2-1} \cong \frac{A_{n,2}}{r^2} = \frac{A_2}{r^2} = \frac{\pi(0.005\text{ m})^2}{(2\text{ m})^2} = 1.963\times10^{-5}\text{ sr}$$

since A_2 were positioned normal to the direction of viewing.

The radiation emitted by A_1 that strikes A_2 is equivalent to the radiation emitted by A_1 through the solid angle $\omega_{2\text{-}1}$. The intensity of the radiation emitted by A_1 is

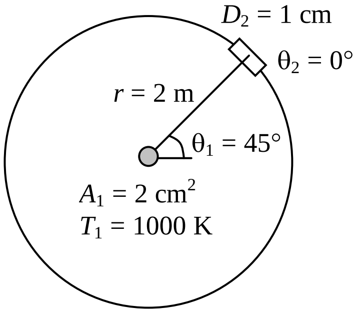
$$I_1 = \frac{E_b(T_1)}{\pi} = \frac{\sigma T_1^4}{\pi} = \frac{(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)(1000\text{ K})^4}{\pi} = 18{,}048\text{ W/m}^2\cdot\text{sr}$$

This value of intensity is the same in all directions since a blackbody is a diffuse emitter. Intensity represents the rate of radiation emission per unit area normal to the direction of emission per unit solid angle. Therefore, the rate of radiation energy emitted by A_1 in the direction of θ_1 through the solid angle $\omega_{2\text{-}1}$ is determined by multiplying I_1 by the area of A_1 normal to θ_1 and the solid angle $\omega_{2\text{-}1}$. That is,

$$\begin{aligned}\dot{Q}_{1-2} &= I_1(A_1\cos\theta_1)\omega_{2-1}\\ &= (18{,}048\text{ W/m}^2\cdot\text{sr})(2\times10^{-4}\cos0°\text{ m}^2)(1.963\times10^{-5}\text{ sr})\\ &= \mathbf{7.087\times10^{-5}\ W}\end{aligned}$$

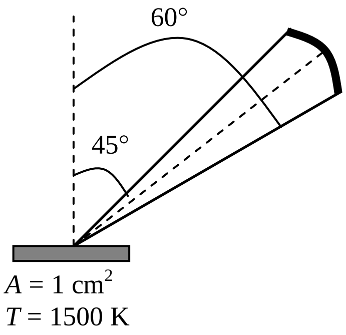
where θ_1 = 0°. Therefore, the radiation emitted from surface A_1 will strike surface A_2 at a rate of 2.835×10^{-4} W.

(*b*) In this orientation, θ_1 = 45° and θ_2 = 0°. Repeating the calculation we obtain the rate of radiation as



$$\begin{aligned}\dot{Q}_{1-2} &= I_1(A_1\cos\theta_1)\omega_{2-1}\\ &= (18{,}048\text{ W/m}^2\cdot\text{sr})(2\times10^{-4}\cos45°\text{ m}^2)(1.963\times10^{-5}\text{ sr})\\ &= \mathbf{5.010\times10^{-5}\ W}\end{aligned}$$

11-34 A small surface emits radiation. The rate of radiation energy emitted through a band is to be determined.



Assumptions Surface *A* emits diffusely as a blackbody.

Analysis The rate of radiation emission from a surface per unit surface area in the direction (θ,ϕ) is given as

$$dE=\frac{d\dot{Q}_e}{dA}=I_e(\theta,\phi)\cos\theta\sin\theta d\theta d\phi$$

The total rate of radiation emission through the band between 60° and 45° can be expressed as

$$E=\int_{\phi=0}^{2\pi}\int_{\theta=45}^{60}I_e(\theta,\phi)\cos\theta\sin\theta\ d\theta\ d\phi=I_b\frac{\pi}{4}=\frac{\sigma T^4}{\pi}\frac{\pi}{4}=\frac{\sigma T^4}{4}$$

since the blackbody radiation intensity is constant (I_b = constant), and

$$\int_{\phi=0}^{2\pi}\int_{\theta=45}^{60}\cos\theta\sin\theta\ d\theta\ d\phi=2\pi\int_{\theta=45}^{60}\cos\theta\sin\theta\ d\theta=\pi(\sin^2 60-\sin^2 45)=\pi/4$$

Approximating a small area as a differential area, the rate of radiation energy emitted from an area of 1 cm^2 in the specified band becomes

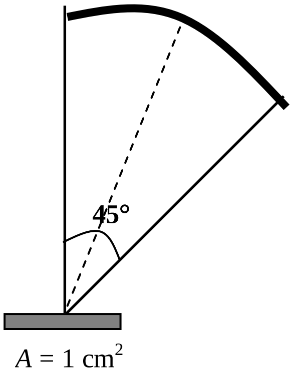
$$\dot{Q}_e=EdA=\frac{\sigma T^4}{4}dA=\frac{(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)(1500\ \text{K})^4}{4}(1\times10^{-4}\ \text{m}^2)=\mathbf{7.18\ W}$$

11-35 A small surface is subjected to uniform incident radiation. The rates of radiation emission through two specified bands are to be determined.

Assumptions The intensity of incident radiation is constant.

Analysis (*a*) The rate at which radiation is incident on a surface per unit surface area in the direction (θ,ϕ) is given as

$$dG = \frac{d\dot{Q}_i}{dA} = I_i(\theta,\phi)\cos\theta\sin\theta d\theta d\phi$$



The total rate of radiation emission through the band between 0° and 45° can be expressed as

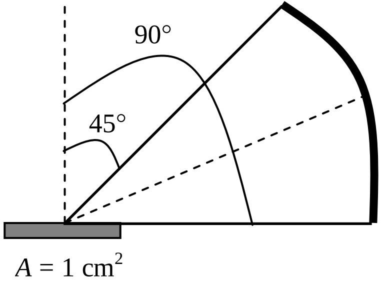
$$G_1 = \int_{\phi=0}^{2\pi}\int_{\theta=0}^{45} I_i(\theta,\phi)\cos\theta\sin\theta\ d\theta\ d\phi = I_i\frac{\pi}{2}$$

since the incident radiation is constant (I_i = constant), and

$$\int_{\phi=0}^{2\pi}\int_{\theta=0}^{45}\cos\theta\sin\theta\ d\theta\ d\phi = 2\pi\int_{\theta=0}^{45}\cos\theta\sin\theta\ d\theta = \pi(\sin^2 45 - \sin^2 0) = \pi/2$$

Approximating a small area as a differential area, the rate of radiation energy emitted from an area of 1 cm^2 in the specified band becomes

$$\dot{Q}_{i,1} = G_1 dA = 0.5\pi I_i dA = 0.5\pi(2.2\times10^4\ \text{W/m}^2\cdot\text{sr})(1\times10^{-4}\ \text{m}^2) = \mathbf{3.46\ W}$$



(*b*) Similarly, the total rate of radiation emission through the band between 45° and 90° can be expressed as

$$G_1 = \int_{\phi=0}^{2\pi}\int_{\theta=45}^{90} I_i(\theta,\phi)\cos\theta\sin\theta\ d\theta\ d\phi = I_i\frac{\pi}{2}$$

since

$$\int_{\phi=0}^{2\pi}\int_{\theta=45}^{90}\cos\theta\sin\theta\ d\theta\ d\phi = 2\pi\int_{\theta=45}^{90}\cos\theta\sin\theta\ d\theta = \pi(\sin^2 90 - \sin^2 45) = \pi/2$$

and

$$\dot{Q}_{i,2} = G_2 dA = 0.5\pi I_i dA = 0.5\pi(2.2\times10^4\ \text{W/m}^2\cdot\text{sr})(1\times10^{-4}\ \text{m}^2) = \mathbf{3.46\ W}$$

Discussion Note that the viewing area for the band 0° - 45° is much smaller, but the radiation energy incident through it is equal to the energy streaming through the remaining area.

Radiation Properties

11-36C The emissivity ε is the ratio of the radiation emitted by the surface to the radiation emitted by a blackbody at the same temperature. The fraction of radiation absorbed by the surface is called the absorptivity α,

$$\varepsilon(T) = \frac{E(T)}{E_b(T)} \quad \text{and} \quad \alpha = \frac{\text{absorbed radiation}}{\text{incident radiation}} = \frac{G_{abs}}{G}$$

When the surface temperature is equal to the temperature of the source of radiation, the total hemispherical emissivity of a surface at temperature T is equal to its total hemispherical absorptivity for radiation coming from a blackbody at the same temperature $\varepsilon_\lambda(T) = \alpha_\lambda(T)$.

11-37C The fraction of irradiation reflected by the surface is called reflectivity ρ and the fraction transmitted is called the transmissivity τ

$$\rho = \frac{G_{ref}}{G} \quad \text{and} \quad \tau = \frac{G_{tr}}{G}$$

Surfaces are assumed to reflect in a perfectly spectral or diffuse manner for simplicity. In spectral (or mirror like) reflection, the angle of reflection equals the angle of incidence of the radiation beam. In diffuse reflection, radiation is reflected equally in all directions.

11-38C A body whose surface properties are independent of wavelength is said to be a graybody. The emissivity of a blackbody is one for all wavelengths, the emissivity of a graybody is between zero and one.

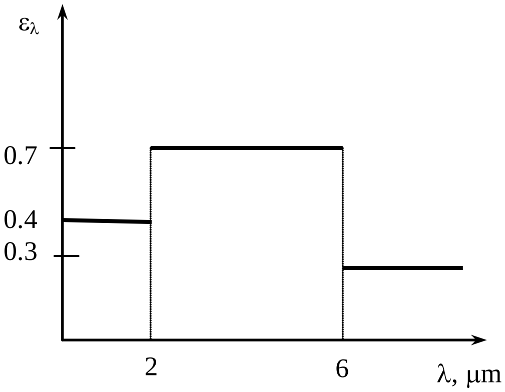
11-39C The heating effect which is due to the non-gray characteristic of glass, clear plastic, or atmospheric gases is known as the greenhouse effect since this effect is utilized primarily in greenhouses. The combustion gases such as CO_2 and water vapor in the atmosphere transmit the bulk of the solar radiation but absorb the infrared radiation emitted by the surface of the earth, acting like a heat trap. There is a concern that the energy trapped on earth will eventually cause global warming and thus drastic changes in weather patterns.

11-40C Glass has a transparent window in the wavelength range 0.3 to 3 μm and it is not transparent to the radiation which has wavelength range greater than 3 μm. Therefore, because the microwaves are in the range of 10^2 to 10^5 μm, the harmful microwave radiation cannot escape from the glass door.

11-41 The variation of emissivity of a surface at a specified temperature with wavelength is given. The average emissivity of the surface and its emissive power are to be determined.

Analysis The average emissivity of the surface can be determined from

$$\varepsilon(T)=\frac{\varepsilon_1\int_0^{\lambda_1}E_{b_\lambda}(T)d\lambda}{\sigma T^4}+\frac{\varepsilon_2\int_{\lambda_1}^{\lambda_2}E_{b_\lambda}(T)d\lambda}{\sigma T^4}+\frac{\varepsilon_3\int_{\lambda_2}^{\infty}E_{b_\lambda}(T)d\lambda}{\sigma T^4}$$
$$=\varepsilon_1 f_{0\text{-}\lambda_1}+\varepsilon_2 f_{\lambda_1\text{-}\lambda_2}+\varepsilon_3 f_{\lambda_2\text{-}\infty}$$
$$=\varepsilon_1 f_{\lambda_1}+\varepsilon_2(f_{\lambda_2}-f_{\lambda_1})+\varepsilon_3(1-f_{\lambda_2})$$



where f_{λ_1} and f_{λ_2} are blackbody radiation functions corresponding to $\lambda_1 T$ and $\lambda_2 T$, determined from

$$\lambda_1 T=(2\ \mu\text{m})(1000\ \text{K})=2000\ \mu\text{mK}\longrightarrow f_{\lambda_1}=0.066728$$
$$\lambda_2 T=(6\ \mu\text{m})(1000\ \text{K})=6000\ \mu\text{mK}\longrightarrow f_{\lambda_2}=0.737818$$

$f_{0-\lambda_1}=f_{\lambda 1}-f_0=f_{\lambda_1}$ since $f_0=0$ and $f_{\lambda_2-\infty}=f_\infty-f_{\lambda_2}$ since $f_\infty=1$.

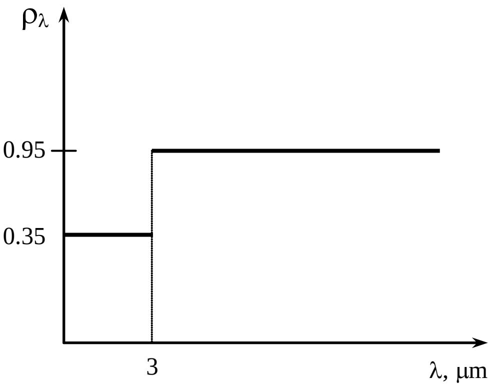
and,

$$\varepsilon=(0.4)0.066728+(0.7)(0.737818-0.066728)+(0.3)(1-0.737818)=\mathbf{0.575}$$

Then the emissive power of the surface becomes

$$E=\varepsilon\sigma T^4=0.575(5.67\times10^{-8}\ \text{W/m}^2\text{.K}^4)(1000\ \text{K})^4=\mathbf{32.6\ kW/m^2}$$

11-42 The variation of reflectivity of a surface with wavelength is given. The average reflectivity, emissivity, and absorptivity of the surface are to be determined for two source temperatures.



Analysis The average reflectivity of this surface for solar radiation (T = 5800 K) is determined to be

$$\lambda T = (3\ \mu\text{m})(5800\ \text{K}) = 17400\ \mu\text{mK} \to \text{f}_\lambda = 0.978746$$

$$\begin{aligned}\rho(T) &= \rho_1 f_{0-\lambda_1}(T) + \rho_2 f_{\lambda_1-\infty}(T)\\ &= \rho_1 f_{\lambda_1} + \rho_2(1 - f_{\lambda_1})\\ &= (0.35)(0.978746) + (0.95)(1 - 0.978746)\\ &= \mathbf{0.362}\end{aligned}$$

Noting that this is an opaque surface, $\tau = 0$

At T = 5800 K: $\alpha + \rho = 1 \longrightarrow \alpha = 1 - \rho = 1 - 0.362 = \mathbf{0.638}$

Repeating calculations for radiation coming from surfaces at T = 300 K,

$$\lambda T = (3\ \mu\text{m})(300\ \text{K}) = 900\ \mu\text{mK} \longrightarrow \text{f}_{\lambda_1} = 0.0001685$$

$$\rho(T) = (0.35)(0.0001685) + (0.95)(1 - 0.0001685) = \mathbf{0.95}$$

At T = 300 K: $\alpha + \rho = 1 \longrightarrow \alpha = 1 - \rho = 1 - 0.95 = \mathbf{0.05}$

and $\varepsilon = \alpha = \mathbf{0.05}$

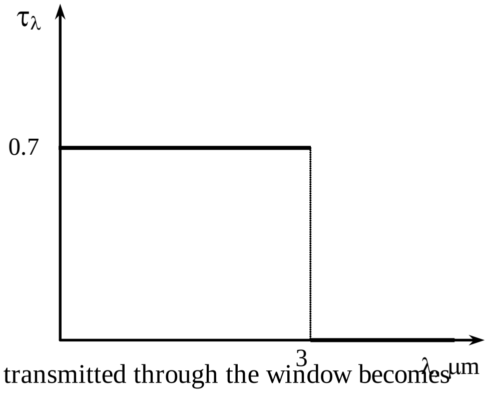
The temperature of the aluminum plate is close to room temperature, and thus emissivity of the plate will be equal to its absorptivity at room temperature. That is,

$$\varepsilon = \varepsilon_{room} = 0.05$$
$$\alpha = \alpha_s = 0.638$$

which makes it suitable as a solar collector. ($\alpha_s = 1$ and $\varepsilon_{\text{room}} = 0$ for an ideal solar collector)

11-43 The variation of transmissivity of the glass window of a furnace at a specified temperature with wavelength is given. The fraction and the rate of radiation coming from the furnace and transmitted through the window are to be determined.

Assumptions The window glass behaves as a black body.



Analysis The fraction of radiation at wavelengths smaller than 3 μm is

$$\lambda T = (3\ \mu\text{m})(1200\ \text{K}) = 3600\ \mu\text{mK} \longrightarrow \text{f}_\lambda = 0.403607$$

The fraction of radiation coming from the furnace and transmitted through the window is

$$\begin{aligned}\tau(T) &= \tau_1 f_\lambda + \tau_2(1 - f_\lambda)\\ &= (0.7)(0.403607) + (0)(1 - 0.403607)\\ &= \mathbf{0.283}\end{aligned}$$

Then the rate of radiation coming from the furnace and transmitted through the window becomes

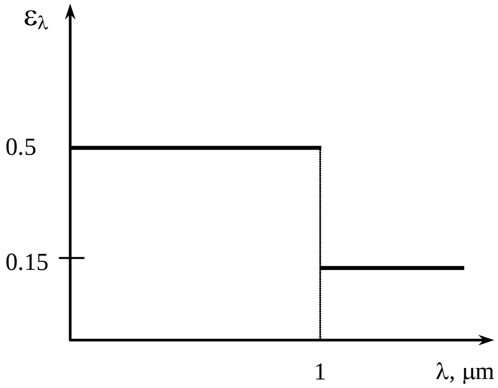
$$G_{tr} = \tau A \sigma T^4 = 0.283(0.25 \times 0.25\ \text{m}^2)(5.67 \times 10^{-8}\ \text{W/m}^2.\text{K}^4)(1200\ \text{K})^4 = \mathbf{2076\ W}$$

11-44 The variation of emissivity of a tungsten filament with wavelength is given. The average emissivity, absorptivity, and reflectivity of the filament are to be determined for two temperatures.

Analysis (*a*) T = 2000 K

$$\lambda_1 T = (1\,\mu\text{m})(2000\text{ K}) = 2000\ \mu\text{mK} \longrightarrow \text{f}_{\lambda_1} = 0.066728$$

The average emissivity of this surface is



$$\begin{aligned}\varepsilon(T) &= \varepsilon_1 f_{\lambda_1} + \varepsilon_2(1 - f_{\lambda_1})\\ &= (0.5)(0.066728) + (0.15)(1 - 0.066728)\\ &= \mathbf{0.173}\end{aligned}$$

From Kirchhoff's law,

$$\varepsilon = \alpha = \mathbf{0.173} \quad \text{(at 2000 K)}$$

and

$$\alpha + \rho = 1 \longrightarrow \rho = 1 - \alpha = 1 - 0.173 = \mathbf{0.827}$$

(*b*) T = 3000 K

$$\lambda_1 T = (1\ \mu\text{m})(3000\text{ K}) = 3000\ \mu\text{mK} \longrightarrow \text{f}_{\lambda_1} = 0.273232$$

Then

$$\begin{aligned}\varepsilon(T) &= \varepsilon_1 f_{\lambda_1} + \varepsilon_2(1 - f_{\lambda_1})\\ &= (0.5)(0.273232) + (0.15)(1 - 0.273232)\\ &= \mathbf{0.246}\end{aligned}$$

From Kirchhoff's law,

$$\varepsilon = \alpha = \mathbf{0.246} \quad \text{(at 3000 K)}$$

and

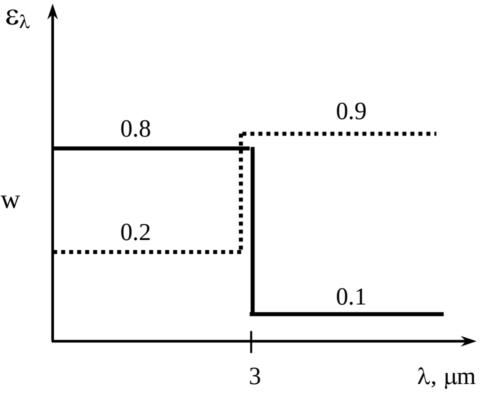
$$\alpha + \rho = 1 \longrightarrow \rho = 1 - \alpha = 1 - 0.246 = \mathbf{0.754}$$

11-45 The variations of emissivity of two surfaces are given. The average emissivity, absorptivity, and reflectivity of each surface are to be determined at the given temperature.

Analysis For the first surface:

$$\lambda_1 T = (3\ \mu\text{m})(3000\ \text{K}) = 9000\ \mu\text{mK} \longrightarrow f_{\lambda_1} = 0.890029$$

The average emissivity of this surface is



$$\begin{aligned}\varepsilon(T) &= \varepsilon_1 f_{\lambda_1} + \varepsilon_2 (1 - f_{\lambda_1}) \\ &= (0.2)(0.890029) + (0.9)(1 - 0.890029) \\ &= \mathbf{0.28}\end{aligned}$$

The absorptivity and reflectivity are determined from Kirchhoff's law

$$\varepsilon = \alpha = \mathbf{0.28} \quad \text{(at 3000 K)}$$

$$\alpha + \rho = 1 \longrightarrow \rho = 1 - \alpha = 1 - 0.28 = \mathbf{0.72}$$

For the second surface:

$$\lambda_1 T = (3\ \mu\text{m})(3000\ \text{K}) = 9000\ \mu\text{mK} \longrightarrow f_{\lambda_1} = 0.890029$$

The average emissivity of this surface is

$$\begin{aligned}\varepsilon(T) &= \varepsilon_1 f_{\lambda_1} + \varepsilon_2 (1 - f_{\lambda_1}) \\ &= (0.8)(0.890029) + (0.1)(1 - 0.890029) \\ &= \mathbf{0.72}\end{aligned}$$

Then,

$$\varepsilon = \alpha = \mathbf{0.72} \quad \text{(at 3000 K)}$$

$$\alpha + \rho = 1 \rightarrow \rho = 1 - \alpha = 1 - 0.72 = \mathbf{0.28}$$

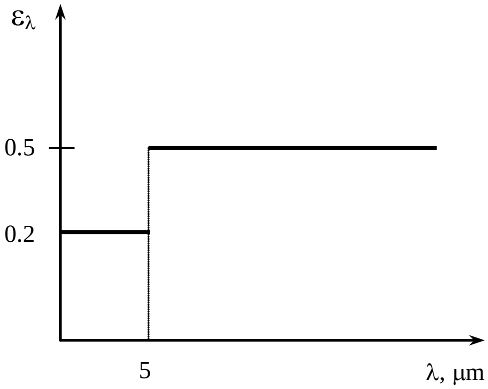
Discussion The second surface is more suitable to serve as a solar absorber since its absorptivity for short wavelength radiation (typical of radiation emitted by a high-temperature source such as the sun) is high, and its emissivity for long wavelength radiation (typical of emitted radiation from the absorber plate) is low.

11-46 The variation of emissivity of a surface with wavelength is given. The average emissivity and absorptivity of the surface are to be determined for two temperatures.

Analysis (*a*) For T = 5800 K:

$$\lambda_1 T = (5\ \mu\text{m})(5800\ \text{K}) = 29{,}000\ \mu\text{mK} \longrightarrow f_{\lambda_1} = 0.99534$$

The average emissivity of this surface is



$$\begin{aligned}\varepsilon(T) &= \varepsilon_1 f_{\lambda_1} + \varepsilon_2(1 - f_{\lambda_1})\\ &= (0.2)(0.99534) + (0.9)(1 - 0.99534)\\ &= \mathbf{0.203}\end{aligned}$$

(*b*) For T = 300 K:

$$\lambda_1 T = (5\mu\text{m})(300\ \text{K}) = 1500\ \mu\text{mK} \longrightarrow f_{\lambda_1} = 0.013754$$

and

$$\begin{aligned}\varepsilon(T) &= \varepsilon_1 f_{\lambda_1} + \varepsilon_2(1 - f_{\lambda_1})\\ &= (0.2)(0.013754) + (0.9)(1 - 0.013754)\\ &= \mathbf{0.89}\end{aligned}$$

The absorptivities of this surface for radiation coming from sources at 5800 K and 300 K are, from Kirchhoff's law,

$\alpha = \varepsilon = \mathbf{0.203}$ (at 5800 K)

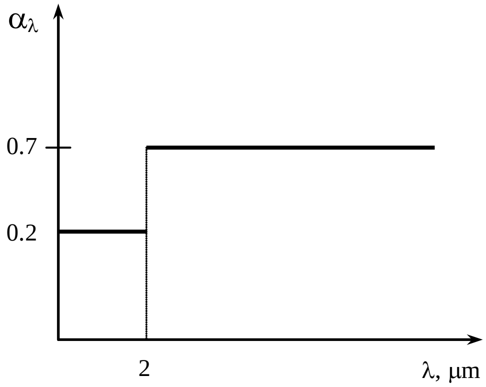
$\alpha = \varepsilon = \mathbf{0.89}$ (at 300 K)

11-47 The variation of absorptivity of a surface with wavelength is given. The average absorptivity, reflectivity, and emissivity of the surface are to be determined at given temperatures.

Analysis For T = 2500 K:

$$\lambda_1 T = (2\ \mu\text{m})(2500\ \text{K}) = 5000\ \mu\text{mK} \longrightarrow f_{\lambda_1} = 0.633747$$

The average absorptivity of this surface is



$$\begin{aligned}\alpha(T) &= \alpha_1 f_{\lambda_1} + \alpha_2(1 - f_{\lambda_1})\\ &= (0.2)(0.633747) + (0.7)(1 - 0.633747)\\ &= \mathbf{0.38}\end{aligned}$$

Then the reflectivity of this surface becomes

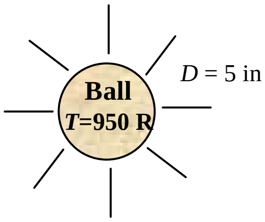
$$\alpha + \rho = 1 \longrightarrow \rho = 1 - \alpha = 1 - 0.38 = \mathbf{0.62}$$

Using Kirchhoff's law, $\alpha = \varepsilon$, the average emissivity of this surface at T = 3000 K is determined to be

$$\lambda T = (2\mu\text{m})(3000\ \text{K}) = 6000\ \mu\text{mK} \longrightarrow f_{\lambda} = 0.737818$$

$$\begin{aligned}\varepsilon(T) &= \varepsilon_1 f_{\lambda_1} + \varepsilon_2(1 - f_{\lambda_1})\\ &= (0.2)(0.737818) + (0.7)(1 - 0.737818)\\ &= \mathbf{0.33}\end{aligned}$$

11-48E A spherical ball emits radiation at a certain rate. The average emissivity of the ball is to be determined at the given temperature.



Analysis The surface area of the ball is

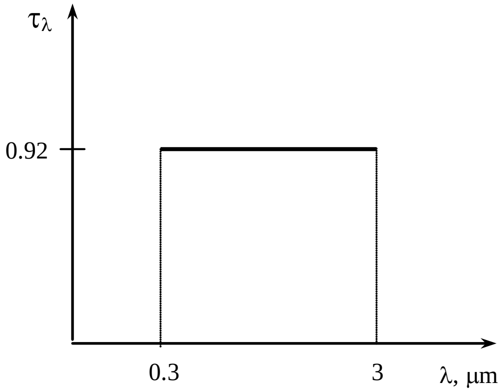
$$A = \pi D^2 = \pi(5/12\text{ ft})^2 = 0.5454\text{ ft}^2$$

Then the average emissivity of the ball at this temperature is determined to be

$$E = \varepsilon A\sigma T^4 \longrightarrow \varepsilon = \frac{E}{A\sigma T^4} = \frac{120\text{ Btu/h}}{(0.5454\text{ ft}^2)(0.1714\times10^{-8}\text{ Btu/h.ft}^2\cdot\text{R}^4)(950\text{ R})^4} = \mathbf{0.158}$$

11-49 The variation of transmissivity of a glass is given. The average transmissivity of the pane at two temperatures and the amount of solar radiation transmitted through the pane are to be determined.

Analysis For T=5800 K:



$$\lambda_1 T_1 = (0.3\ \mu\text{m})(5800\text{ K}) = 1740\ \mu\text{mK} \longrightarrow f_{\lambda_1} = 0.035$$

$$\lambda_2 T_1 = (3\ \mu\text{m})(5800\text{ K}) = 17{,}400\ \mu\text{mK} \longrightarrow f_{\lambda_2} = 0.977$$

The average transmissivity of this surface is

$$\tau(T) = \tau_1(f_{\lambda_2} - f_{\lambda_1}) = (0.9)(0.977 - 0.035) = \mathbf{0.848}$$

For T=300 K:

$$\lambda_1 T_2 = (0.3\ \mu\text{m})(300\text{ K}) = 90\ \mu\text{mK} \longrightarrow f_{\lambda_1} = 0.0$$

$$\lambda_2 T_2 = (3\ \mu\text{m})(300\text{ K}) = 900\ \mu\text{mK} \longrightarrow f_{\lambda_2} = 0.0001685$$

Then,

$$\tau(T) = \tau_1(f_{\lambda_2} - f_{\lambda_1}) = (0.9)(0.0001685 - 0.0) = \mathbf{0.00015 \approx 0}$$

The amount of solar radiation transmitted through this glass is

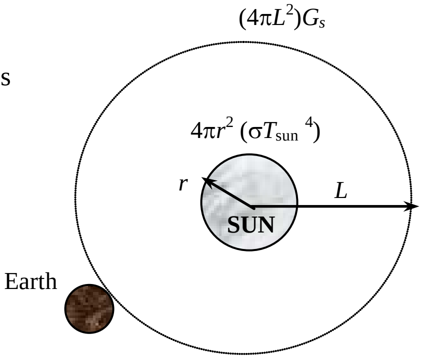
$$G_{\text{tr}} = \tau G_{\text{incident}} = 0.848(650\text{ W/m}^2) = \mathbf{551\ W/m^2}$$

Atmospheric and Solar Radiation

11-50C The solar constant represents the rate at which solar energy is incident on a surface normal to sun's rays at the outer edge of the atmosphere when the earth is at its mean distance from the sun. It value is $G_s = 1353\ \text{W/m}^2$. The solar constant is used to estimate the effective surface temperature of the sun from the requirement that

$$(4\pi L^2)G_{s1} = (4\pi r^2)\sigma T_{sun}{}^4$$

where L is the mean distance between the sun and the earth and r is the radius of the sun. If the distance between the earth and the sun doubled, the value of G_s drops to one-fourth since



$$4\pi(2L)^2 G_{s2} = (4\pi r^2)\sigma T_{sun}{}^4$$

$$16\pi L^2 G_{s2} = (4\pi r^2)\sigma T_{sun}{}^4$$

$$16\pi L^2 G_{s2} = 4\pi L^2 G_{s1} \longrightarrow \mathbf{G_{s2} = \frac{G_{s1}}{4}}$$

11-51C The amount of solar radiation incident on earth will decrease by a factor of

$$\text{Reduction factor} = \frac{\sigma T_{sun}{}^4}{\sigma T_{sun,new}{}^4} = \frac{5762^4}{2000^4} = 68.9$$

(or to 1.5% of what it was). Also, the fraction of radiation in the visible range would be much smaller.

11-52C Air molecules scatter blue light much more than they do red light. This molecular scattering in all directions is what gives the sky its bluish color. At sunset, the light travels through a thicker layer of atmosphere, which removes much of the blue from the natural light, letting the red dominate.

11-53C The reason for different seasons is the tilt of the earth which causes the solar radiation to travel through a longer path in the atmosphere in winter, and a shorter path in summer. Therefore, the solar radiation is attenuated much more strongly in winter.

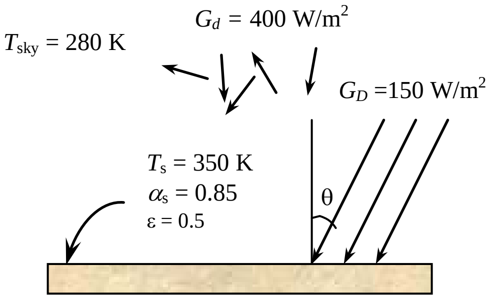
11-54C The gas molecules and the suspended particles in the atmosphere emit radiation as well as absorbing it. Although this emission is far from resembling the distribution of radiation from a blackbody, it is found convenient in radiation calculations to treat the atmosphere as a blackbody at some lower fictitious temperature that emits an equivalent amount of radiation energy. This fictitious temperature is called the effective sky temperature T_{sky}.

11-55C There is heat loss from both sides of the bridge (top and bottom surfaces of the bridge) which reduces temperature of the bridge surface to very low values. The relatively warm earth under a highway supply heat to the surface continuously, making the water on it less likely to freeze.

11-56C Due to its nearly horizontal orientation, windshield exchanges heat with the sky that is at very low temperature. Side windows on the other hand exchange heat with surrounding surfaces that are at relatively high temperature.

11-57C Because of different wavelengths of solar radiation and radiation originating from surrounding bodies, the surfaces usually have quite different absorptivities. Solar radiation is concentrated in the short wavelength region and the surfaces in the infrared region.

11-58 A surface is exposed to solar and sky radiation. The net rate of radiation heat transfer is to be determined.



Properties The solar absorptivity and emissivity of the surface are given to $\alpha_s = 0.85$ and $\varepsilon = 0.5$.

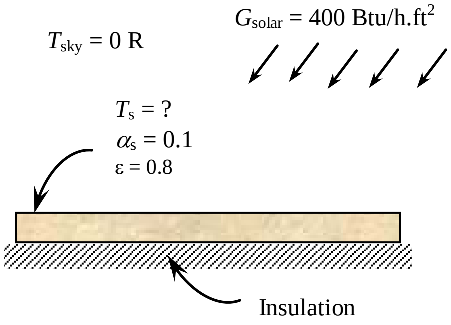
Analysis The total solar energy incident on the surface is

$$\begin{aligned} G_{solar} &= G_D \cos\theta + G_d \\ &= (350\ \text{W/m}^2)\cos 30° + (400\ \text{W/m}^2) \\ &= 703.1\ \text{W/m}^2 \end{aligned}$$

Then the net rate of radiation heat transfer in this case becomes

$$\begin{aligned} \dot{q}_{net,rad} &= \alpha_s G_{solar} - \varepsilon\sigma(T_s{}^4 - T_{sky}{}^4) \\ &= 0.85(703.1\ \text{W/m}^2) - 0.5(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)\left[(350\ \text{K})^4 - (280\ \text{K})^4\right] \\ &= \mathbf{347\ W/m^2}\ \ \text{(to the surface)} \end{aligned}$$

11-59E A surface is exposed to solar and sky radiation. The equilibrium temperature of the surface is to be determined.

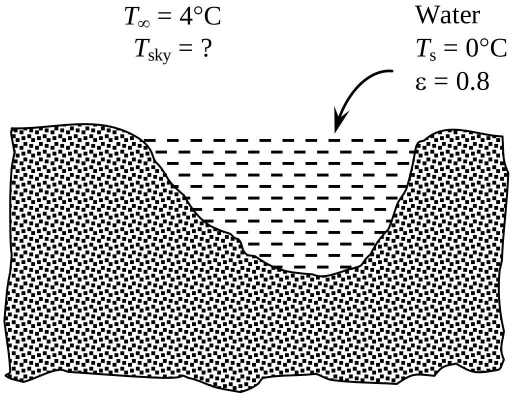


Properties The solar absorptivity and emissivity of the surface are given to $\alpha_s = 0.10$ and $\varepsilon = 0.8$.

Analysis The equilibrium temperature of the surface in this case is

$$\begin{aligned} \dot{q}_{net,rad} &= \alpha_s G_{solar} - \varepsilon\sigma(T_s{}^4 - T_{sky}{}^4) = 0 \\ \alpha_s G_{solar} &= \varepsilon\sigma(T_s{}^4 - T_{sky}{}^4) \\ 0.1(400\ \text{Btu/h.ft}^2) &= 0.8(0.1714\times10^{-8}\ \text{Btu/h.ft}^2\cdot\text{R}^4)\left[T_s{}^4 - (0\ \text{R})^4\right] \\ T_s &= \mathbf{413.3\ R} \end{aligned}$$

11-60 Water is observed to have frozen one night while the air temperature is above freezing temperature. The effective sky temperature is to be determined.



Properties The emissivity of water is ε = 0.95 (Table A-21).

Analysis Assuming the water temperature to be 0°C, the value of the effective sky temperature is determined from an energy balance on water to be

$$h(T_{air} - T_{surface}) = \varepsilon\sigma(T_s^{\,4} - T_{sky}^{\,4})$$

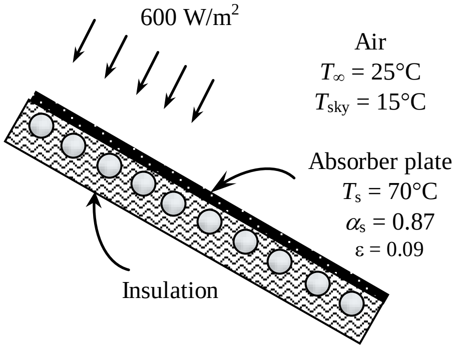
and

$$(18\ \text{W/m}^2\cdot°\text{C})(4°\text{C} - 0°\text{C}) = 0.95(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)\left[(273\ \text{K})^4 - T_{sky}^{\,4}\right]$$

$$\longrightarrow T_{sky} = \mathbf{254.8\ K}$$

Therefore, the effective sky temperature must have been below 255 K.

11-61 The absorber plate of a solar collector is exposed to solar and sky radiation. The net rate of solar energy absorbed by the absorber plate is to be determined.



Properties The solar absorptivity and emissivity of the surface are given to $\alpha_s = 0.87$ and ε = 0.09.

Analysis The net rate of solar energy delivered by the absorber plate to the water circulating behind it can be determined from an energy balance to be

$$\dot{q}_{net} = \dot{q}_{gain} - \dot{q}_{loss}$$

$$\dot{q}_{net} = \alpha_s G_{solar} - \left[\varepsilon\sigma(T_s^{\,4} - T_{sky}^{\,4}) + h(T_s - T_{air})\right]$$

Then,

$$\begin{aligned}\dot{q}_{net} &= 0.87(600\ \text{W/m}^2) - 0.09(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)\left[(70+273\ \text{K})^4 - (15+273\ \text{K})^4\right]\\ &\quad -(10\ \text{W/m}^2\cdot\text{K})(70°\text{C} - 25°\text{C})\\ &= \mathbf{36.5\ W/m^2}\end{aligned}$$

Therefore, heat is gained by the plate and transferred to water at a rate of 36.5 W per m^2 surface area.

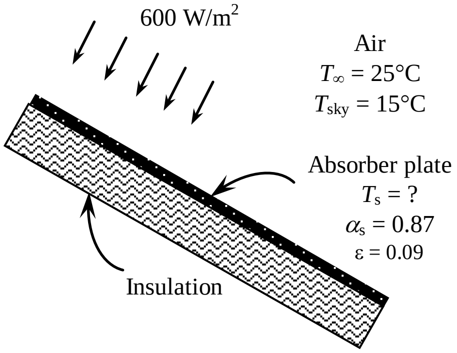
α_s
$\dot{q}_{net}$ [W/m^2]

11-63 The absorber surface of a solar collector is exposed to solar and sky radiation. The equilibrium temperature of the absorber surface is to be determined if the backside of the plate is insulated.



Properties The solar absorptivity and emissivity of the surface are given to $\alpha_s = 0.87$ and $\varepsilon = 0.09$.

Analysis The backside of the absorbing plate is insulated (instead of being attached to water tubes), and thus

$$\dot{q}_{net} = 0$$

$$\alpha_s G_{solar} = \varepsilon\sigma(T_s^{\ 4} - T_{sky}^{\ 4}) + h(T_s - T_{air})$$

$$(0.87)(600\ \text{W/m}^2) = (0.09)(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)\left[(T_s)^4 - (288\ \text{K})^4\right] + (10\ \text{W/m}^2\cdot\text{K})(T_s - 298\ \text{K})$$

$$T_s = \mathbf{346\ K}$$

Special Topic: Solar Heat Gain Through Windows

11-64C (*a*) The spectral distribution of solar radiation beyond the earth's atmosphere resembles the energy emitted by a black body at 5982°C, with about 39 percent in the visible region (0.4 to 0.7 μm), and the 52 percent in the near infrared region (0.7 to 3.5 μm). (*b*) At a solar altitude of 41.8°, the total energy of direct solar radiation incident at sea level on a clear day consists of about 3 percent ultraviolet, 38 percent visible, and 59 percent infrared radiation.

11-65C A window that transmits visible part of the spectrum while absorbing the infrared portion is ideally suited for minimizing the air-conditioning load since such windows provide maximum daylighting and minimum solar heat gain. The ordinary window glass approximates this behavior remarkably well.

11-66C The **solar heat gain coefficient (**SHGC) is defined as the fraction of incident solar radiation that enters through the glazing. The solar heat gain of a glazing relative to the solar heat gain of a reference glazing, typically that of a standard 3 mm (1/8 in) thick double-strength clear window glass sheet whose SHGC is 0.87, is called the **shading coefficient**. They are related to each other by

$$\text{SC} = \frac{\text{Solar heat gain of product}}{\text{Solar heat gain of reference glazing}} = \frac{\text{SHGC}}{\text{SHGC}_{\text{ref}}} = \frac{\text{SHGC}}{0.87} = 1.15\times\text{SHGC}$$

For single pane clear glass window, SHGC = 0.87 and SC = 1.0.

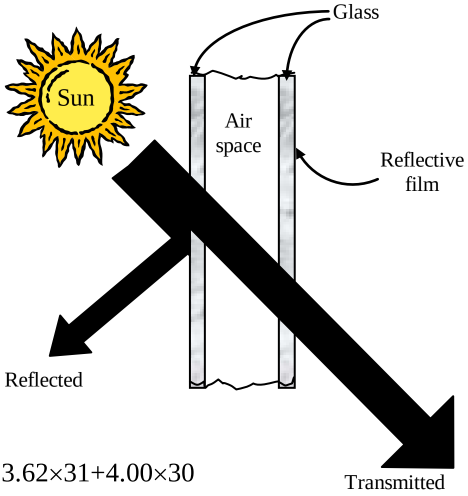
11-67C The SC (shading coefficient) of a device represents the solar heat gain relative to the solar heat gain of a reference glazing, typically that of a standard 3 mm (1/8 in) thick double-strength clear window glass sheet whose SHGC is 0.87. The shading coefficient of a 3-mm thick *clear glass* is SC = 1.0 whereas SC = 0.88 for 3-mm thick *heat absorbing glass*.

11-68C A device that blocks solar radiation and thus reduces the solar heat gain is called a shading device. External shading devices are more effective in reducing the solar heat gain since they intercept sun's rays before they reach the glazing. The solar heat gain through a window can be reduced by as much as 80 percent by exterior shading. *Light colored* shading devices maximize the back reflection and thus minimize the solar gain. *Dark colored* shades, on the other hand, minimize the back refection and thus maximize the solar heat gain.

11-69C A low-e coating on the inner surface of a window glass reduces both the (*a*) heat loss in winter and (*b*) heat gain in summer. This is because the radiation heat transfer to or from the window is proportional to the emissivity of the inner surface of the window. In winter, the window is colder and thus radiation heat loss from the room to the window is low. In summer, the window is hotter and the radiation transfer from the window to the room is low.

11-70C Glasses coated with reflective films on the outer surface of a window glass reduces solar heat both in summer and in winter.

11-71 The net annual cost savings due to installing reflective coating on the West windows of a building and the simple payback period are to be determined.



Assumptions **1** The calculations given below are for an average year. **2** The unit costs of electricity and natural gas remain constant.

Analysis Using the daily averages for each month and noting the number of days of each month, the total solar heat flux incident on the glazing during summer and winter months are determined to be

$$Q_{\text{solar, summer}} = 4.24\times30 + 4.16\times31 + 3.93\times31 + 3.48\times30$$
$$= 482 \text{ kWh/year}$$

$$Q_{\text{solar, winter}} = 2.94\times31 + 2.33\times30 + 2.07\times31 + 2.35\times31 + 3.03\times28 + 3.62\times31 + 4.00\times30$$
$$= 615 \text{ kWh/year}$$

Then the decrease in the annual cooling load and the increase in the annual heating load due to reflective film become

$$\text{Cooling load decrease} = Q_{\text{solar, summer}} A_{\text{glazing}} (\text{SHGC}_{\text{without film}} - \text{SHGC}_{\text{with film}})$$
$$= (482 \text{ kWh/year})(60 \text{ m}^2)(0.766-0.261)$$
$$= 14{,}605 \text{ kWh/year}$$

$$\text{Heating load increase} = Q_{\text{solar, winter}} A_{\text{glazing}} (\text{SHGC}_{\text{without film}} - \text{SHGC}_{\text{with film}})$$
$$= (615 \text{ kWh/year})(60 \text{ m}^2)(0.766-0.261)$$
$$= 18{,}635 \text{ kWh/year} = 635.8 \text{ therms/year}$$

since 1 therm = 29.31 kWh. The corresponding decrease in cooling costs and increase in heating costs are

Decrease in cooling costs = (Cooling load decrease)(Unit cost of electricity)/COP

= (14,605 kWh/year)($0.09/kWh)/3.2 = $411/year

Increase in heating costs = (Heating load increase)(Unit cost of fuel)/Efficiency

= (635.8 therms/year)($0.45/therm)/0.80 = $358/year

Then the net annual cost savings due to reflective films become

Cost Savings = Decrease in cooling costs - Increase in heating costs = $411 - 358 = **$53/year**

The implementation cost of installing films is

$$\text{Implementation Cost} = (\$20/\text{m}^2)(60 \text{ m}^2) = \$1200$$

This gives a simple payback period of

$$\text{Simple payback period} = \frac{\text{Implementation cost}}{\text{Annual cost savings}} = \frac{\$1200}{\$53/\text{year}} = \mathbf{23\ years}$$

Discussion The reflective films will pay for themselves in this case in about 23 years, which is unacceptable to most manufacturers since they are not usually interested in any energy conservation measure which does not pay for itself within 3 years.

11-72 A house located at 40º N latitude has ordinary double pane windows. The total solar heat gain of the house at 9:00, 12:00, and 15:00 solar time in July and the total amount of solar heat gain per day for an average day in January are to be determined.

Assumptions The calculations are performed for an average day in a given month.

Properties The shading coefficient of a double pane window with 6-mm thick glasses is SC = 0.82 (Table 11-5). The incident radiation at different windows at different times are given as (Table 11-4)

Month	Time	Solar radiation incident on the surface, W/m^2			
		North	East	South	West
July	9:00	117	701	190	114
July	12:00	138	149	395	149
July	15:00	117	114	190	701
January	Daily total	446	1863	5897	1863

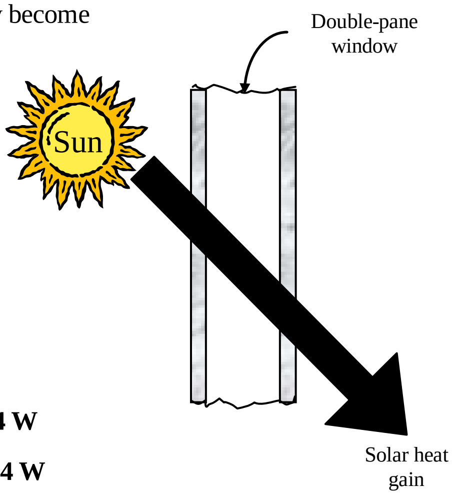
Analysis The solar heat gain coefficient (SHGC) of the windows is determined from Eq.11-57 to be

$$\text{SHGC} = 0.87\times\text{SC} = 0.87\times0.82 = 0.7134$$

The rate of solar heat gain is determined from

$$\dot{Q}_{\text{solar gain}} = SHGC\times A_{\text{glazing}}\times\dot{q}_{\text{solar, incident}} = 0.7134\times A_{\text{glazing}}\times\dot{q}_{\text{solar, incident}}$$

Then the rates of heat gain at the 4 walls at 3 different times in July become



North wall:

$$\dot{Q}_{\text{solar gain, 9:00}} = 0.7134\times(4\text{ m}^2)\times(117\text{ W/m}^2) = \mathbf{334\ W}$$
$$\dot{Q}_{\text{solar gain,12:00}} = 0.7134\times(4\text{ m}^2)\times(138\text{ W/m}^2) = \mathbf{394\ W}$$
$$\dot{Q}_{\text{solar gain, 15:00}} = 0.7134\times(4\text{ m}^2)\times(117\text{ W/m}^2) = \mathbf{334\ W}$$

East wall:

$$\dot{Q}_{\text{solar gain, 9:00}} = 0.7134\times(6\text{ m}^2)\times(701\text{ W/m}^2) = \mathbf{3001\ W}$$
$$\dot{Q}_{\text{solar gain,12:00}} = 0.7134\times(6\text{ m}^2)\times(149\text{ W/m}^2) = \mathbf{638\ W}$$
$$\dot{Q}_{\text{solar gain, 15:00}} = 0.7134\times(6\text{ m}^2)\times(114\text{ W/m}^2) = \mathbf{488\ W}$$

South wall:

$$\dot{Q}_{\text{solar gain, 9:00}} = 0.7134\times(8\text{ m}^2)\times(190\text{ W/m}^2) = \mathbf{1084\ W}$$
$$\dot{Q}_{\text{solar gain,12:00}} = 0.7134\times(8\text{ m}^2)\times(395\text{ W/m}^2) = \mathbf{2254\ W}$$
$$\dot{Q}_{\text{solar gain, 15:00}} = 0.7134\times(8\text{ m}^2)\times(190\text{ W/m}^2) = \mathbf{1084\ W}$$

West wall:

$$\dot{Q}_{\text{solar gain, 9:00}} = 0.7134\times(6\text{ m}^2)\times(114\text{ W/m}^2) = \mathbf{488\ W}$$
$$\dot{Q}_{\text{solar gain,12:00}} = 0.7134\times(6\text{ m}^2)\times(149\text{ W/m}^2) = \mathbf{638\ W}$$
$$\dot{Q}_{\text{solar gain, 15:00}} = 0.7134\times(6\text{ m}^2)\times(701\text{ W/m}^2) = \mathbf{3001\ W}$$

Similarly, the solar heat gain of the house through all of the windows in January is determined to be

January:

$$\dot{Q}_{\text{solar gain, North}} = 0.7134\times(4\text{ m}^2)\times(446\text{ Wh/m}^2\cdot\text{day}) = 1273\text{ Wh/day}$$
$$\dot{Q}_{\text{solar gain,East}} = 0.7134\times(6\text{ m}^2)\times(1863\text{ Wh/m}^2\cdot\text{day}) = 7974\text{ Wh/day}$$
$$\dot{Q}_{\text{solar gain, South}} = 0.7134\times(8\text{ m}^2)\times(5897\text{ Wh/m}^2\cdot\text{day}) = 33{,}655\text{ Wh/day}$$
$$\dot{Q}_{\text{solar gain,West}} = 0.7134\times(6\text{ m}^2)\times(1863\text{ Wh/m}^2\cdot\text{day}) = 7974\text{ Wh/day}$$

Therefore, for an average day in January,

$$\dot{Q}_{\text{solar gain per day}} = 446+1863+5897+1863 = 58{,}876\text{ Wh/day} \cong \mathbf{58.9\ kWh/day}$$

11-73 A house located at 40° N latitude has gray-tinted double pane windows. The total solar heat gain of the house at 9:00, 12:00, and 15:00 solar time in July and the total amount of solar heat gain per day for an average day in January are to be determined.

Assumptions The calculations are performed for an average day in a given month.

Properties The shading coefficient of a gray-tinted double pane window with 6-mm thick glasses is SC = 0.58 (Table 11-5). The incident radiation at different windows at different times are given as (Table 11-4)

Month	Time	Solar radiation incident on the surface, W/m^2			
		North	East	South	West
July	9:00	117	701	190	114
July	12:00	138	149	395	149
July	15:00	117	114	190	701
January	Daily total	446	1863	5897	1863

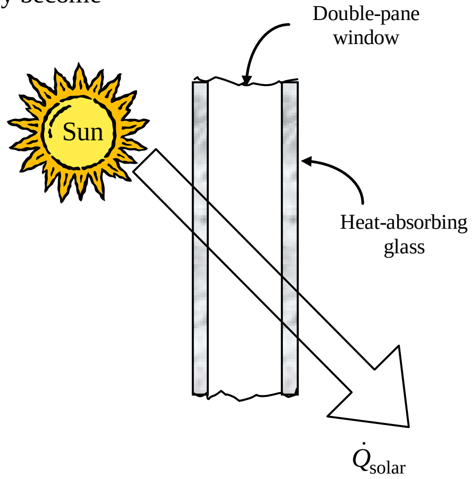
Analysis The solar heat gain coefficient (SHGC) of the windows is determined from Eq.11-57 to be

$$\text{SHGC} = 0.87\times\text{SC} = 0.87\times 0.58 = 0.5046$$

The rate of solar heat gain is determined from

$$\dot{Q}_{\text{solar gain}} = SHGC\times A_{\text{glazing}}\times \dot{q}_{\text{solar, incident}} = 0.5046\times A_{\text{glazing}}\times \dot{q}_{\text{solar, incident}}$$

Then the rates of heat gain at the 4 walls at 3 different times in July become



North wall:

$$\dot{Q}_{\text{solar gain, 9:00}} = 0.5046\times(4\text{ m}^2)\times(117\text{ W/m}^2) = \mathbf{236\text{ W}}$$
$$\dot{Q}_{\text{solar gain,12:00}} = 0.5046\times(4\text{ m}^2)\times(138\text{ W/m}^2) = \mathbf{279\text{ W}}$$
$$\dot{Q}_{\text{solar gain, 15:00}} = 0.5046\times(4\text{ m}^2)\times(117\text{ W/m}^2) = \mathbf{236\text{ W}}$$

East wall:

$$\dot{Q}_{\text{solar gain, 9:00}} = 0.5046\times(6\text{ m}^2)\times(701\text{ W/m}^2) = \mathbf{2122\text{ W}}$$
$$\dot{Q}_{\text{solar gain,12:00}} = 0.5046\times(6\text{ m}^2)\times(149\text{ W/m}^2) = \mathbf{461\text{ W}}$$
$$\dot{Q}_{\text{solar gain, 15:00}} = 0.5046\times(6\text{ m}^2)\times(114\text{ W/m}^2) = \mathbf{345\text{ W}}$$

South wall:

$$\dot{Q}_{\text{solar gain, 9:00}} = 0.5046\times(8\text{ m}^2)\times(190\text{ W/m}^2) = \mathbf{7674\text{ W}}$$
$$\dot{Q}_{\text{solar gain,12:00}} = 0.5046\times(8\text{ m}^2)\times(395\text{ W/m}^2) = \mathbf{1595\text{ W}}$$
$$\dot{Q}_{\text{solar gain, 15:00}} = 0.5046\times(8\text{ m}^2)\times(190\text{ W/m}^2) = \mathbf{767\text{ W}}$$

West wall:

$$\dot{Q}_{\text{solar gain, 9:00}} = 0.5046\times(6\text{ m}^2)\times(114\text{ W/m}^2) = \mathbf{345\text{ W}}$$
$$\dot{Q}_{\text{solar gain,12:00}} = 0.5046\times(6\text{ m}^2)\times(149\text{ W/m}^2) = \mathbf{451\text{ W}}$$
$$\dot{Q}_{\text{solar gain, 15:00}} = 0.5046\times(6\text{ m}^2)\times(701\text{ W/m}^2) = \mathbf{2122\text{ W}}$$

Similarly, the solar heat gain of the house through all of the windows in January is determined to be

January:

$$\dot{Q}_{\text{solar gain, North}} = 0.5046\times(4\text{ m}^2)\times(446\text{ Wh/m}^2\cdot\text{day}) = 900\text{ Wh/day}$$
$$\dot{Q}_{\text{solar gain,East}} = 0.5046\times(6\text{ m}^2)\times(1863\text{ Wh/m}^2\cdot\text{day}) = 5640\text{ Wh/day}$$
$$\dot{Q}_{\text{solar gain, South}} = 0.5046\times(8\text{ m}^2)\times(5897\text{ Wh/m}^2\cdot\text{day}) = 23{,}805\text{ Wh/day}$$
$$\dot{Q}_{\text{solar gain,West}} = 0.5046\times(6\text{ m}^2)\times(1863\text{ Wh/m}^2\cdot\text{day}) = 5640\text{ Wh/day}$$

Therefore, for an average day in January,

$$\dot{Q}_{\text{solar gain per day}} = 900+5640+23{,}805+5640 = 35{,}985\text{ Wh/day} = \mathbf{35.895\text{ kWh/day}}$$

11-74 A building at 40° N latitude has double pane heat absorbing type windows that are equipped with light colored venetian blinds. The total solar heat gains of the building through the south windows at solar noon in April for the cases of with and without the blinds are to be determined.

Assumptions The calculations are performed for an "average" day in April, and may vary from location to location.

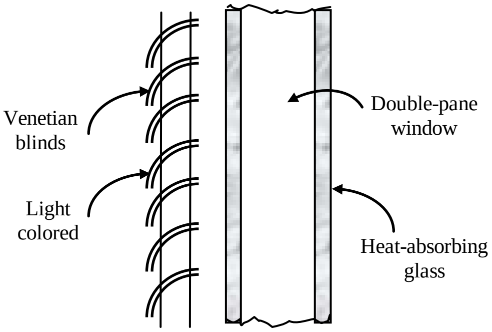
Properties The shading coefficient of a double pane heat absorbing type windows is SC = 0.58 (Table 11-5). It is given to be SC = 0.30 in the case of blinds. The solar radiation incident at a South-facing surface at 12:00 noon in April is 559 W/m^2 (Table 11-4).

Analysis The solar heat gain coefficient (SHGC) of the windows without the blinds is determined from Eq.11-57 to be

$$\text{SHGC} = 0.87\times\text{SC} = 0.87\times0.58 = 0.5046$$

Then the rate of solar heat gain through the window becomes

$$\begin{aligned}\dot{Q}_{\text{solar gain, no blinds}} &= SHGC\times A_{\text{glazing}}\times\dot{q}_{\text{solar, incident}}\\ &= 0.5046(200\ \text{m}^2)(559\ \text{W/m}^2)\\ &= \mathbf{56{,}414\ W}\end{aligned}$$



In the case of windows equipped with venetian blinds, the SHGC and the rate of solar heat gain become

$$\text{SHGC} = 0.87\times\text{SC} = 0.87\times0.30 = 0.261$$

Then the rate of solar heat gain through the window becomes

$$\begin{aligned}\dot{Q}_{\text{solar gain, no blinds}} &= SHGC\times A_{\text{glazing}}\times\dot{q}_{\text{solar, incident}}\\ &= 0.261(200\ \text{m}^2)(559\ \text{W/m}^2)\\ &= \mathbf{29{,}180\ W}\end{aligned}$$

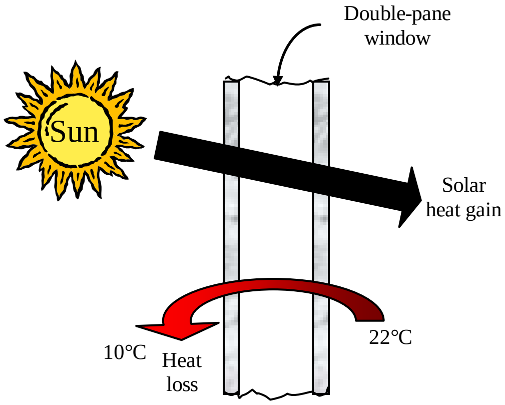
Discussion Note that light colored venetian blinds significantly reduce the solar heat, and thus air-conditioning load in summers.

11-75 A house has double door type windows that are double pane with 6.4 mm of air space and aluminum frames and spacers. It is to be determined if the house is losing more or less heat than it is gaining from the sun through an east window in a typical day in January.

Assumptions **1** The calculations are performed for an "average" day in January. **2** Solar data at 40° latitude can also be used for a location at 39° latitude.

Properties The shading coefficient of a double pane window with 3-mm thick clear glass is SC = 0.88 (Table 11-5). The overall heat transfer coefficient for double door type windows that are double pane with 6.4 mm of air space and aluminum frames and spacers is 4.55 W/m^2.°C. (Table 9-6). The total solar radiation incident at an East-facing surface in January during a typical day is 1863 Wh/m^2 (Table 11-4).

Analysis The solar heat gain coefficient (SHGC) of the windows is determined from Eq.11-57 to be



$$\text{SHGC} = 0.87\times\text{SC} = 0.87\times 0.88 = 0.7656$$

Then the solar heat gain through the window per unit area becomes

$$\begin{aligned} Q_{\text{solar gain}} &= SHGC\times A_{\text{glazing}}\times q_{\text{solar, daily total}} \\ &= 0.7656(1\,\text{m}^2)(1863\,\text{Wh/m}^2) \\ &= \mathbf{1426\ Wh = 1.426\ kWh} \end{aligned}$$

The heat loss through a unit area of the window during a 24-h period is

$$\begin{aligned} Q_{\text{loss, window}} &= \dot{Q}_{\text{loss, window}}\Delta t = U_{\text{window}} A_{\text{window}}(T_i - T_{0,\text{ave}})(1\,\text{day}) \\ &= (4.55\,\text{W/m}^2\cdot{}^\circ\text{C})(1\,\text{m}^2)(22-10)^\circ\text{C}(24\,\text{h}) \\ &= \mathbf{1310\ Wh = 1.31\ kWh} \end{aligned}$$

Therefore, the house is **gaining** more heat than it is loosing through the East windows during a typical day in January.

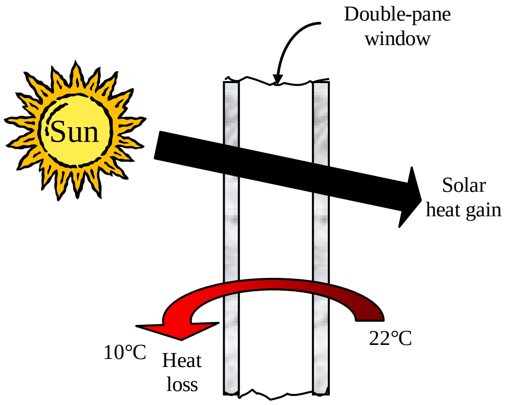
11-76 A house has double door type windows that are double pane with 6.4 mm of air space and aluminum frames and spacers. It is to be determined if the house is losing more or less heat than it is gaining from the sun through a South window in a typical day in January.

Assumptions **1** The calculations are performed for an "average" day in January. **2** Solar data at 40° latitude can also be used for a location at 39° latitude.

Properties The shading coefficient of a double pane window with 3-mm thick clear glass is SC = 0.88 (Table 11-5). The overall heat transfer coefficient for double door type windows that are double pane with 6.4 mm of air space and aluminum frames and spacers is 4.55 W/m^2.°C (Table 9-6). The total solar radiation incident at a South-facing surface in January during a typical day is 5897 Wh/m^2 (Table 11-5).

Analysis The solar heat gain coefficient (SHGC) of the windows is determined from Eq.11-57 to be

$$\text{SHGC} = 0.87\times\text{SC} = 0.87\times0.88 = 0.7656$$



Then the solar heat gain through the window per unit area becomes

$$\begin{aligned} Q_{\text{solar gain}} &= SHGC\times A_{\text{glazing}}\times q_{\text{solar, daily total}} \\ &= 0.7656(1\,\text{m}^2)(5897\ \text{Wh/m}^2) \\ &= \mathbf{4515\ Wh = 4.515\ kWh} \end{aligned}$$

The heat loss through a unit area of the window during a 24-h period is

$$\begin{aligned} Q_{\text{loss, window}} &= \dot{Q}_{\text{loss, window}}\Delta t = U_{\text{window}}A_{\text{window}}(T_i - T_{0,\text{ave}})(1\,\text{day}) \\ &= (4.55\ \text{W/m}^2\cdot°\text{C})(1\,\text{m}^2)(22-10)°\text{C}(24\,\text{h}) \\ &= \mathbf{1310\ Wh = 1.31\,kWh} \end{aligned}$$

Therefore, the house is **gaining** much more heat than it is loosing through the South windows during a typical day in January.

11-77E A house has 1/8-in thick single pane windows with aluminum frames on a West wall. The rate of net heat gain (or loss) through the window at 3 PM during a typical day in January is to be determined.

Assumptions **1** The calculations are performed for an "average" day in January. **2** The frame area relative to glazing area is small so that the glazing area can be taken to be the same as the window area.

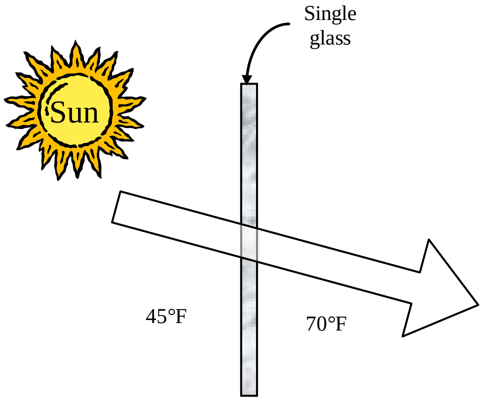
Properties The shading coefficient of a 1/8-in thick single pane window is SC = 1.0 (Table 11-5). The overall heat transfer coefficient for 1/8-in thick single pane windows with aluminum frames is 6.63 $\text{W/m}^2.°\text{C} = 1.17\ \text{Btu/h.ft}^2.°\text{F}$ (Table 9-6). The total solar radiation incident at a West-facing surface at 3 PM in January during a typical day is $557\ \text{W/m}^2 = 177\ \text{Btu/h.ft}^2$ (Table 11-4).

Analysis The solar heat gain coefficient (SHGC) of the windows is determined from Eq.11-57 to be

$$\text{SHGC} = 0.87\times\text{SC} = 0.87\times1.0 = 0.87$$

The window area is: $A_{\text{window}} = (9\ \text{ft})(15\ \text{ft}) = 135\ \text{ft}^2$

Then the rate of solar heat gain through the window at 3 PM becomes



$$\begin{aligned}\dot{Q}_{\text{solar gain, 3 PM}} &= SHGC\times A_{\text{glazing}}\times\dot{q}_{\text{solar, 3 PM}}\\ &= 0.87(135\ \text{ft}^2)(177\ \text{Btu/h.ft}^2)\\ &= 20{,}789\ \text{Btu/h}\end{aligned}$$

The rate of heat loss through the window at 3 PM is

$$\begin{aligned}\dot{Q}_{\text{loss, window}} &= U_{\text{window}}A_{\text{window}}(T_i - T_0)\\ &= (1.17\ \text{Btu/h}\cdot\text{ft}^2\cdot°\text{F})(135\ \text{ft}^2)(70-45)°\text{F}\\ &= 3949\ \text{Btu/h}\end{aligned}$$

The house will be gaining heat at 3 PM since the solar heat gain is larger than the heat loss. The rate of net heat gain through the window is

$$\dot{Q}_{\text{net}} = \dot{Q}_{\text{solar gain, 3 PM}} - \dot{Q}_{\text{loss, window}} = 20{,}789 - 394 = \mathbf{16{,}840\ Btu/h}$$

Discussion The actual heat gain will be less because of the area occupied by the window frame.

11-78 A building located near 40º N latitude has equal window areas on all four sides. The side of the building with the highest solar heat gain in summer is to be determined.

Assumptions The shading coefficients of windows on all sides of the building are identical.

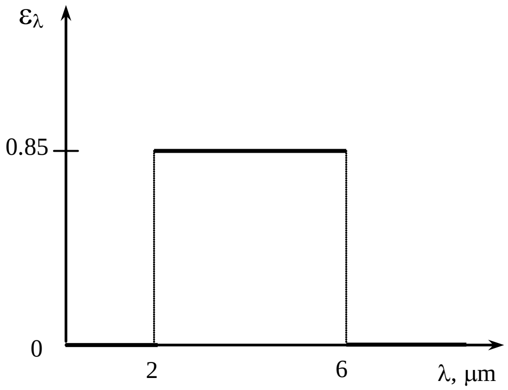
Analysis The reflective films should be installed on the side that receives the most incident solar radiation in summer since the window areas and the shading coefficients on all four sides are identical. The incident solar radiation at different windows in July are given to be (Table 11-5)

Month	Time	The daily total solar radiation incident on the surface, Wh/m^2			
		North	East	South	West
July	Daily total	1621	4313	2552	4313

Therefore, the reflective film should be installed on the **East** or **West** windows (instead of the South windows) in order to minimize the solar heat gain and thus the cooling load of the building.

Review Problems

11-79 The variation of emissivity of an opaque surface at a specified temperature with wavelength is given. The average emissivity of the surface and its emissive power are to be determined.



Analysis The average emissivity of the surface can be determined from

$$\varepsilon(T) = \varepsilon_1 f_{\lambda_1} + \varepsilon_2 (f_{\lambda_2} - f_{\lambda_1}) + \varepsilon_3 (1 - f_{\lambda_2})$$

where f_{λ_1} and f_{λ_2} are blackbody radiation functions corresponding to $\lambda_1 T$ and $\lambda_2 T$. These functions are determined from Table 11-1 to be

$$\lambda_1 T = (2\ \mu\text{m})(1200\text{ K}) = 2400\ \mu\text{mK} \longrightarrow f_{\lambda_1} = 0.140256$$

$$\lambda_2 T = (6\ \mu\text{m})(1200\text{ K}) = 7200\ \mu\text{mK} \longrightarrow f_{\lambda_2} = 0.819217$$

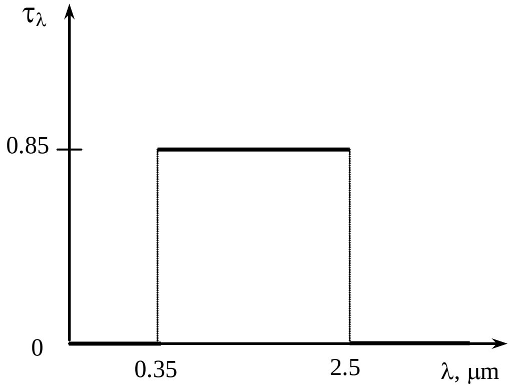
and

$$\varepsilon = (0.0)(0.140256) + (0.85)(0.819217 - 0.140256) + (0.0)(1 - 0.819217) = \mathbf{0.577}$$

Then the emissive flux of the surface becomes

$$E = \varepsilon\sigma T^4 = (0.577)(5.67\times10^{-8}\text{ W/m}^2.\text{K}^4)(1200\text{ K})^4 = \mathbf{67{,}853\ \ W/m^2}$$

11-80 The variation of transmissivity of glass with wavelength is given. The transmissivity of the glass for solar radiation and for light are to be determined.



Analysis For solar radiation, T = 5800 K. The average transmissivity of the surface can be determined from

$$\tau(T) = \tau_1 f_{\lambda_1} + \tau_2 (f_{\lambda_2} - f_{\lambda_1}) + \tau_3 (1 - f_{\lambda_2})$$

where f_{λ_1} and f_{λ_2} are blackbody radiation functions corresponding to $\lambda_1 T$ and $\lambda_2 T$. These functions are determined from Table 11-1 to be

$$\lambda_1 T = (0.35\ \mu\text{m})(5800\text{ K}) = 2030\ \mu\text{mK} \longrightarrow f_{\lambda_1} = 0.071852$$

$$\lambda_2 T = (2.5\ \mu\text{m})(5800\text{ K}) = 14{,}500\ \mu\text{mK} \longrightarrow f_{\lambda_2} = 0.966440$$

and

$$\tau = (0.0)(0.071852) + (0.85)(0.966440 - 0.071852) + (0.0)(1 - 0.966440) = \mathbf{0.760}$$

For light, we take T = 300 K. Repeating the calculations at this temperature we obtain

$$\lambda_1 T = (0.35\ \mu\text{m})(300\text{ K}) = 105\ \mu\text{mK} \longrightarrow f_{\lambda_1} = 0.00$$

$$\lambda_2 T = (2.5\ \mu\text{m})(300\text{ K}) = 750\ \mu\text{mK} \longrightarrow f_{\lambda_2} = 0.000012$$

$$\tau = (0.0)(0.00) + (0.85)(0.000012 - 0.00) + (0.0)(1 - 0.000012) = \mathbf{0.00001}$$

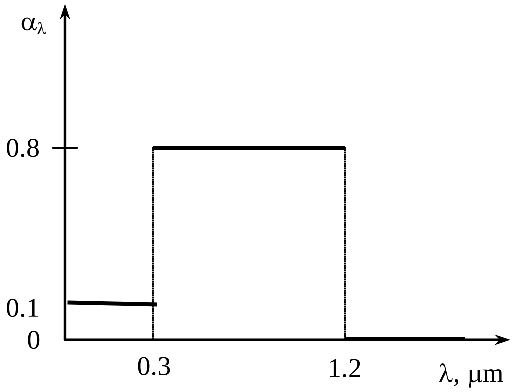
11-81 A hole is drilled in a spherical cavity. The maximum rate of radiation energy streaming through the hole is to be determined.

Analysis The maximum rate of radiation energy streaming through the hole is the blackbody radiation, and it can be determined from

$$E = A\sigma T^4 = \pi(0.0025\ \text{m})^2(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)(600\ \text{K})^4 = \mathbf{0.144\ W}$$

The result would not change for a different diameter of the cavity.

11-82 The variation of absorptivity of a surface with wavelength is given. The average absorptivity of the surface is to be determined for two source temperatures.



Analysis (*a*) T = 1000 K. The average absorptivity of the surface can be determined from

$$\begin{aligned}\alpha(T) &= \alpha_1 f_{0\text{-}\lambda_1} + \alpha_2 f_{\lambda_1\text{-}\lambda_2} + \alpha_3 f_{\lambda_2\text{-}\infty}\\ &= \alpha_1 f_{\lambda_1} + \alpha_2(f_{\lambda_2} - f_{\lambda_1}) + \alpha_3(1 - f_{\lambda_2})\end{aligned}$$

where f_{λ_1} and f_{λ_2} are blackbody radiation functions corresponding to $\lambda_1 T$ and $\lambda_2 T$, determined from

$$\lambda_1 T = (0.3\ \mu\text{m})(1000\ \text{K}) = 300\ \mu\text{mK} \longrightarrow f_{\lambda_1} = 0.0$$

$$\lambda_2 T = (1.2\ \mu\text{m})(1000\ \text{K}) = 1200\ \mu\text{mK} \longrightarrow f_{\lambda_2} = 0.002134$$

$$f_{0-\lambda_1} = f_{\lambda 1} - f_0 = f_{\lambda_1} \text{ since } f_0 = 0 \text{ and } f_{\lambda_2-\infty} = f_\infty - f_{\lambda_2} \text{ since } f_\infty = 1.$$

and,

$$\alpha = (0.1)0.0 + (0.8)(0.002134 - 0.0) + (0.0)(1 - 0.002134) = \mathbf{0.0017}$$

(*a*) T = 3000 K.

$$\lambda_1 T = (0.3\ \mu\text{m})(3000\ \text{K}) = 900\ \mu\text{mK} \longrightarrow f_{\lambda_1} = 0.000169$$

$$\lambda_2 T = (1.2\ \mu\text{m})(3000\ \text{K}) = 3600\ \mu\text{mK} \longrightarrow f_{\lambda_2} = 0.403607$$

$$\alpha = (0.1)0.000169 + (0.8)(0.403607 - 0.000169) + (0.0)(1 - 0.403607) = \mathbf{0.323}$$

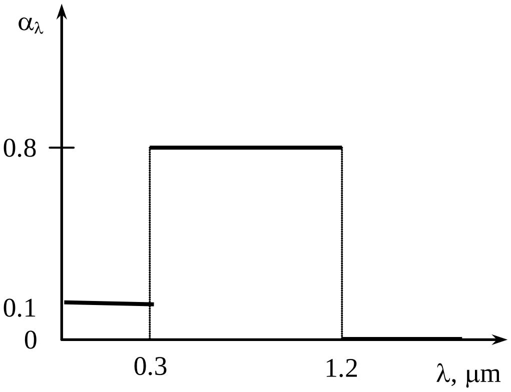
11-83 The variation of absorptivity of a surface with wavelength is given. The surface receives solar radiation at a specified rate. The solar absorptivity of the surface and the rate of absorption of solar radiation are to be determined.

Analysis For solar radiation, T = 5800 K. The solar absorptivity of the surface is

$$\lambda_1 T = (0.3\,\mu\text{m})(5800\text{ K}) = 1740\,\mu\text{mK} \to \text{f}_{\lambda_1} = 0.033454$$

$$\lambda_2 T = (1.2\,\mu\text{m})(5800\text{ K}) = 6960\,\mu\text{mK} \to \text{f}_{\lambda_2} = 0.805713$$

$$\begin{aligned}\alpha &= (0.1)0.033454 + (0.8)(0.805713 - 0.033454)\\ &\quad + (0.0)(1 - 0.805713)\\ &= \mathbf{0.621}\end{aligned}$$



The rate of absorption of solar radiation is determined from

$$E_{\text{absorbed}} = \alpha I = 0.621(820\text{ W/m}^2) = \mathbf{509\ W/m^2}$$

11-84 The spectral transmissivity of a glass cover used in a solar collector is given. Solar radiation is incident on the collector. The solar flux incident on the absorber plate, the transmissivity of the glass cover for radiation emitted by the absorber plate, and the rate of heat transfer to the cooling water are to be determined.

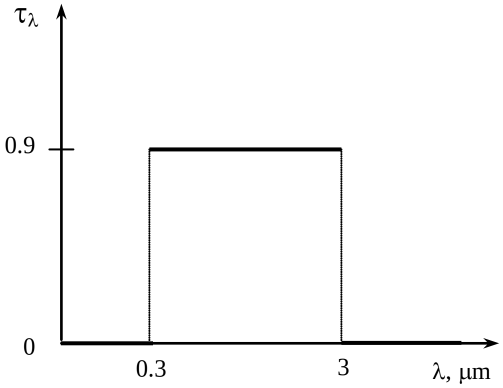
Analysis (*a*) For solar radiation, T = 5800 K. The average transmissivity of the surface can be determined from

$$\tau(T) = \tau_1 f_{\lambda_1} + \tau_2 (f_{\lambda_2} - f_{\lambda_1}) + \tau_3 (1 - f_{\lambda_2})$$

where f_{λ_1} and f_{λ_2} are blackbody radiation functions corresponding to $\lambda_1 T$ and $\lambda_2 T$. These functions are determined from Table 11-1 to be

$$\lambda_1 T = (0.3\,\mu\text{m})(5800\text{ K}) = 1740\,\mu\text{mK} \longrightarrow \text{f}_{\lambda_1} = 0.033454$$

$$\lambda_2 T = (3\,\mu\text{m})(5800\text{ K}) = 17{,}400\,\mu\text{mK} \longrightarrow \text{f}_{\lambda_2} = 0.978746$$



and

$$\tau = (0.0)(0.033454) + (0.9)(0.978746 - 0.033454) + (0.0)(1 - 0.978746) = 0.851$$

Since the absorber plate is black, all of the radiation transmitted through the glass cover will be absorbed by the absorber plate and therefore, the solar flux incident on the absorber plate is same as the radiation absorbed by the absorber plate:

$$E_{\text{abs. plate}} = \tau I = 0.851(950\text{ W/m}^2) = \mathbf{808.5\ W/m^2}$$

(*b*) For radiation emitted by the absorber plate, we take T = 300 K, and calculate the transmissivity as follows:

$$\lambda_1 T = (0.3\,\mu\text{m})(300\text{ K}) = 90\,\mu\text{mK} \longrightarrow \text{f}_{\lambda_1} = 0.0$$

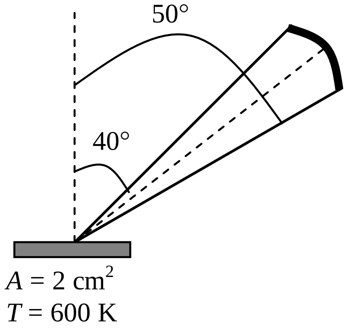
$$\lambda_2 T = (3\,\mu\text{m})(300\text{ K}) = 900\,\mu\text{mK} \longrightarrow \text{f}_{\lambda_2} = 0.000169$$

$$\tau = (0.0)(0.0) + (0.9)(0.000169 - 0.0) + (0.0)(1 - 0.000169) = \mathbf{0.00015}$$

(*c*) The rate of heat transfer to the cooling water is the difference between the radiation absorbed by the absorber plate and the radiation emitted by the absorber plate, and it is determined from

$$\dot{Q}_{\text{water}} = (\tau_{\text{solar}} - \tau_{\text{room}})I = (0.851 - 0.00015)(950\text{ W/m}^2) = \mathbf{808.3\ W/m^2}$$

11-85 A small surface emits radiation. The rate of radiation energy emitted through a band is to be determined.



Assumptions Surface A emits diffusely as a blackbody.

Analysis The rate of radiation emission from a surface per unit surface area in the direction (θ,ϕ) is given as

$$dE = \frac{d\dot{Q}_e}{dA} = I_e(\theta,\phi)\cos\theta\sin\theta d\theta d\phi$$

The total rate of radiation emission through the band between 40° and 50° can be expressed as

$$E = \int_{\phi=0}^{2\pi}\int_{\theta=40}^{50} I_e(\theta,\phi)\cos\theta\sin\theta\ d\theta\ d\phi = I_b(0.1736\pi) = \frac{\sigma T^4}{\pi}(0.1736\pi) = 0.1736\sigma T^4$$

since the blackbody radiation intensity is constant (I_b = constant), and

$$\int_{\phi=0}^{2\pi}\int_{\theta=40}^{50}\cos\theta\sin\theta\ d\theta\ d\phi = 2\pi\int_{\theta=40}^{50}\cos\theta\sin\theta\ d\theta = \pi(\sin^2 50 - \sin^2 40) = 0.1736\pi$$

Approximating a small area as a differential area, the rate of radiation energy emitted from an area of 1 cm^2 in the specified band becomes

$$\dot{Q}_e = EdA = 0.1736\sigma T^4 dA = 0.1736\times(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)(600\ \text{K})^4(1\times10^{-4}\ \text{m}^2) = \mathbf{0.128\ W}$$

11-86 ….. 11-87 Design and Essay Problems

Chapter 12
RADIATION HEAT TRANSFER

View Factors

12-1C The view factor $F_{i \to j}$ represents the fraction of the radiation leaving surface i that strikes surface j directly. The view factor from a surface to itself is non-zero for concave surfaces.

12-2C The pair of view factors $F_{i \to j}$ and $F_{j \to i}$ are related to each other by the reciprocity rule $A_i F_{ij} = A_j F_{ji}$ where A_i is the area of the surface i and A_j is the area of the surface j. Therefore,

$$A_1 F_{12} = A_2 F_{21} \longrightarrow F_{12} = \frac{A_2}{A_1} F_{21}$$

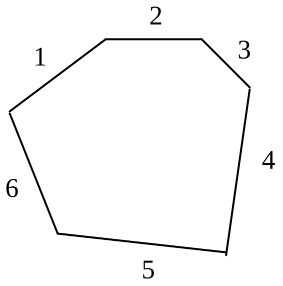
12-3C The summation rule for an enclosure and is expressed as $\sum_{j=1}^{N} F_{i \to j} = 1$ where N is the number of surfaces of the enclosure. It states that the sum of the view factors from surface i of an enclosure to all surfaces of the enclosure, including to itself must be equal to unity.

The superposition rule is stated as the view factor from a surface i to a surface j is equal to the sum of the view factors from surface i to the parts of surface j, $F_{1 \to (2,3)} = F_{1 \to 2} + F_{1 \to 3}$.

12-4C The cross-string method is applicable to geometries which are very long in one direction relative to the other directions. By attaching strings between corners the Crossed-Strings Method is expressed as

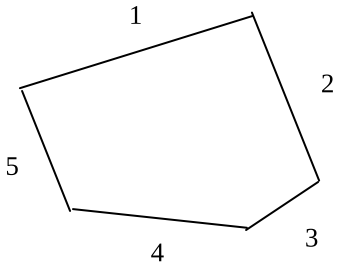
$$F_{i \to j} = \frac{\sum \text{Crossed strings} - \sum \text{Uncrossed strings}}{2 \times \text{string on surface } i}$$

12-5 An enclosure consisting of six surfaces is considered. The number of view factors this geometry involves and the number of these view factors that can be determined by the application of the reciprocity and summation rules are to be determined.



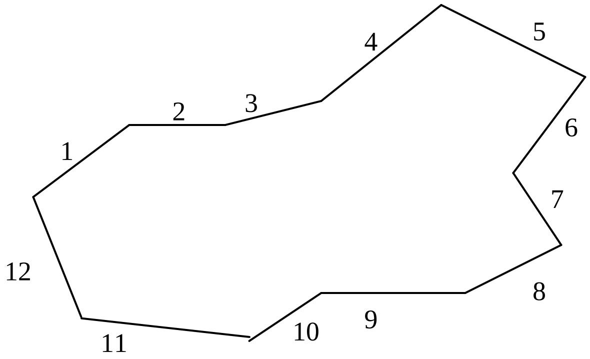
Analysis A seven surface enclosure (N=6) involves $N^2 = 6^2 = \mathbf{36}$ view factors and we need to determine $\frac{N(N-1)}{2} = \frac{6(6-1)}{2} = 15$ view factors directly. The remaining 36-15 = **21** of the view factors can be determined by the application of the reciprocity and summation rules.

12-6 An enclosure consisting of five surfaces is considered. The number of view factors this geometry involves and the number of these view factors that can be determined by the application of the reciprocity and summation rules are to be determined.



Analysis A five surface enclosure (N=5) involves $N^2 = 5^2 = \mathbf{25}$ view factors and we need to determine $\frac{N(N-1)}{2} = \frac{5(5-1)}{2} = 10$ view factors directly. The remaining 25-10 = **15** of the view factors can be determined by the application of the reciprocity and summation rules.

12-7 An enclosure consisting of twelve surfaces is considered. The number of view factors this geometry involves and the number of these view factors that can be determined by the application of the reciprocity and summation rules are to be determined.



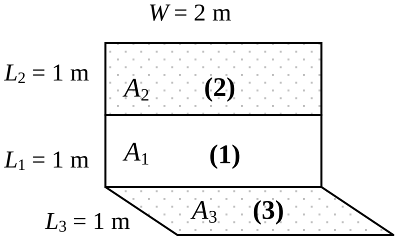
Analysis A twelve surface enclosure (N=12) involves $N^2 = 12^2 = \mathbf{144}$ view factors and we need to determine $\frac{N(N-1)}{2} = \frac{12(12-1)}{2} = 66$ view factors directly. The remaining 144-66 = **78** of the view factors can be determined by the application of the reciprocity and summation rules.

12-8 The view factors between the rectangular surfaces shown in the figure are to be determined.

Assumptions The surfaces are diffuse emitters and reflectors.

Analysis From Fig. 12-6,

$$\left.\begin{array}{l}\dfrac{L_3}{W}=\dfrac{1}{2}=0.5\\[2ex]\dfrac{L1}{W}=\dfrac{1}{2}=0.5\end{array}\right\}F_{31}=0.24$$



and

$$\left.\begin{array}{l}\dfrac{L_3}{W}=\dfrac{1}{2}=0.5\\[2ex]\dfrac{L_1+L_2}{W}=\dfrac{2}{2}=1\end{array}\right\}F_{3\to(1+2)}=0.29$$

We note that $A_1 = A_3$. Then the reciprocity and superposition rules gives

$$\mathrm{A}_1F_{13}=A_3F_{31}\longrightarrow F_{13}=F_{31}=\mathbf{0.24}$$

$$F_{3\to(1+2)}=F_{31}+F_{32}\longrightarrow\quad 0.29=0.24+F_{32}\longrightarrow F_{32}=0.05$$

Finally, $A_2=A_3\longrightarrow F_{23}=F_{32}=\mathbf{0.05}$

12-9 A cylindrical enclosure is considered. The view factor from the side surface of this cylindrical enclosure to its base surface is to be determined.

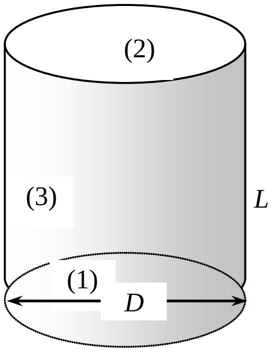
Assumptions The surfaces are diffuse emitters and reflectors.

Analysis We designate the surfaces as follows:

Base surface by (1),

top surface by (2), and

side surface by (3).



Then from Fig. 12-7 (or Table 12-1 for better accuracy)

$$\left.\begin{array}{l}\dfrac{L}{r_1}=\dfrac{r_1}{r_1}=1\\[2ex]\dfrac{r_2}{L}=\dfrac{r_2}{r_2}=1\end{array}\right\}F_{12}=F_{21}=0.38$$

$$\text{summation rule}: F_{11}+F_{12}+F_{13}=1$$

$$0+0.38+F_{13}=1\longrightarrow F_{13}=0.62$$

$$\text{reciprocity rule}: A_1F_{13}=A_3F_{31}\longrightarrow F_{31}=\frac{A_1}{A_3}F_{13}=\frac{\pi r_1^2}{2\pi r_1 L}F_{13}=\frac{\pi r_1^2}{2\pi r_1(r_1)}F_{13}=\frac{1}{2}(0.62)=\mathbf{0.31}$$

Discussion This problem can be solved more accurately by using the view factor relation from Table 12-1 to be

$$R_1=\frac{r_1}{L}=\frac{r_1}{r_1}=1$$

$$R_2=\frac{r_2}{L}=\frac{r_2}{r_2}=1$$

$$S=1+\frac{1+R_2^2}{R_1^2}=1+\frac{1+1^2}{1^2}=3$$

$$F_{12}=\tfrac{1}{2}\left\{S-\left[S^2-4\left(\frac{R_2}{R_1}\right)^2\right]^{0.5}\right\}=\tfrac{1}{2}\left\{3-\left[3^2-4\left(\frac{1}{1}\right)^2\right]^{0.5}\right\}=0.382$$

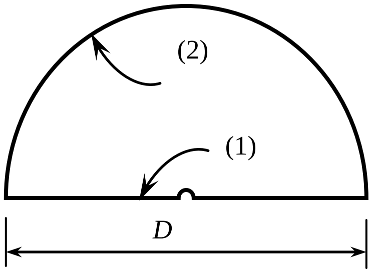
$$F_{13}=1-F_{12}=1-0.382=0.618$$

$$\text{reciprocity rule}: A_1F_{13}=A_3F_{31}\longrightarrow F_{31}=\frac{A_1}{A_3}F_{13}=\frac{\pi r_1^2}{2\pi r_1 L}F_{13}=\frac{\pi r_1^2}{2\pi r_1(r_1)}F_{13}=\frac{1}{2}(0.618)=\mathbf{0.309}$$

12-10 A semispherical furnace is considered. The view factor from the dome of this furnace to its flat base is to be determined.

Assumptions The surfaces are diffuse emitters and reflectors.

Analysis We number the surfaces as follows:



(1): circular base surface

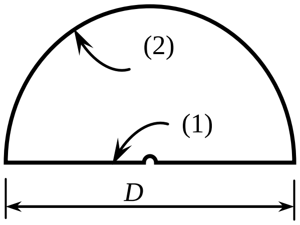
(2): dome surface

Surface (1) is flat, and thus $F_{11} = 0$.

$$\text{Summation rule: } F_{11} + F_{12} = 1 \rightarrow F_{12} = 1$$

$$\text{reciprocity rule: } A_1 F_{12} = A_2 F_{21} \longrightarrow F_{21} = \frac{A_1}{A_2} F_{12} = \frac{A_1}{A_2}(1) = \frac{\frac{\pi D^2}{4}}{\frac{\pi D^2}{2}} = \frac{1}{2} = \mathbf{0.5}$$

12-11 Two view factors associated with three very long ducts with different geometries are to be determined.



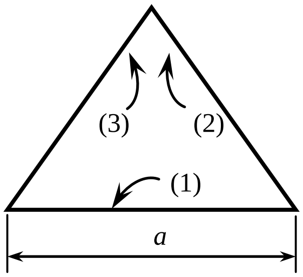
Assumptions **1** The surfaces are diffuse emitters and reflectors. **2** End effects are neglected.

Analysis (*a*) Surface (1) is flat, and thus $F_{11} = 0$.

$$\text{summation rule: } F_{11} + F_{12} = 1 \rightarrow F_{12} = \mathbf{1}$$

$$\text{reciprocity rule: } A_1 F_{12} = A_2 F_{21} \longrightarrow F_{21} = \frac{A_1}{A_2} F_{12} = \frac{Ds}{\left(\frac{\pi D}{2}\right)s}(1) = \frac{2}{\pi} = \mathbf{0.64}$$

(*b*) Noting that surfaces 2 and 3 are symmetrical and thus $F_{12} = F_{13}$, the summation rule gives



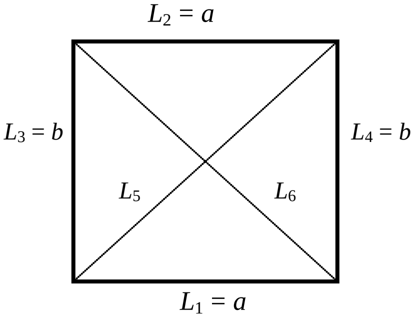
$$F_{11} + F_{12} + F_{13} = 1 \longrightarrow 0 + F_{12} + F_{13} = 1 \longrightarrow F_{12} = \mathbf{0.5}$$

Also by using the equation obtained in Example 12-4,

$$F_{12} = \frac{L_1 + L_2 - L_3}{2L_1} = \frac{a + b - b}{2a} = \frac{a}{2a} = \frac{1}{2} = \mathbf{0.5}$$

$$\text{reciprocity rule: } A_1 F_{12} = A_2 F_{21} \longrightarrow F_{21} = \frac{A_1}{A_2} F_{12} = \frac{a}{b}\left(\frac{1}{2}\right) = \mathbf{\frac{a}{2b}}$$

(*c*) Applying the crossed-string method gives



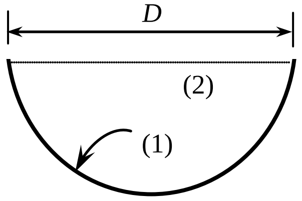
$$F_{12} = F_{21} = \frac{(L_5 + L_6) - (L_3 + L_4)}{2L_1}$$

$$= \frac{2\sqrt{a^2 + b^2} - 2b}{2a} = \mathbf{\frac{\sqrt{a^2 + b^2} - b}{a}}$$

12-12 View factors from the very long grooves shown in the figure to the surroundings are to be determined.

Assumptions **1** The surfaces are diffuse emitters and reflectors. **2** End effects are neglected.

Analysis (*a*) We designate the circular dome surface by (1) and the imaginary flat top surface by (2). Noting that (2) is flat,

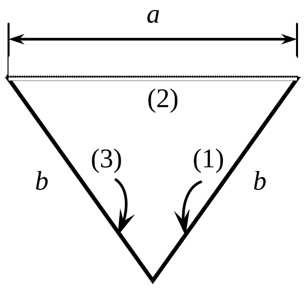


$$F_{22} = 0$$

$$\text{summation rule: } F_{21} + F_{22} = 1 \longrightarrow F_{21} = 1$$

$$\text{reciprocity rule: } A_1 F_{12} = A_2 F_{21} \longrightarrow F_{12} = \frac{A_2}{A_1} F_{21} = \frac{D}{\frac{\pi D}{2}}(1) = \frac{2}{\pi} = \mathbf{0.64}$$

(*b*) We designate the two identical surfaces of length *b* by (1) and (3), and the imaginary flat top surface by (2). Noting that (2) is flat,



$$F_{22} = 0$$

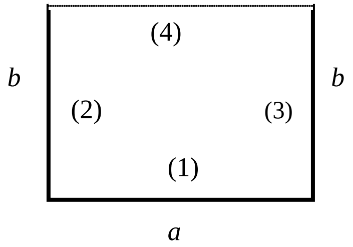
$$\text{summation rule: } F_{21} + F_{22} + F_{23} = 1 \longrightarrow F_{21} = F_{23} = 0.5 \quad \text{(symmetry)}$$

$$\text{summation rule: } F_{22} + F_{2\to(1+3)} = 1 \longrightarrow F_{2\to(1+3)} = 1$$

$$\text{reciprocity rule: } A_2 F_{2\to(1+3)} = A_{(1+3)} F_{(1+3)\to 2}$$

$$\longrightarrow F_{(1+3)\to 2} = F_{(1+3)\to surr} = \frac{A_2}{A_{(1+3)}}(1) = \frac{\mathbf{a}}{\mathbf{2b}}$$

(*c*) We designate the bottom surface by (1), the side surfaces by (2) and (3), and the imaginary top surface by (4). Surface 4 is flat and is completely surrounded by other surfaces. Therefore, $F_{44} = 0$ and $F_{4\to(1+2+3)} = 1$.



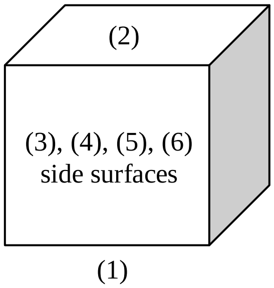
$$\text{reciprocity rule: } A_4 F_{4\to(1+2+3)} = A_{(1+2+3)} F_{(1+2+3)\to 4}$$

$$\longrightarrow F_{(1+2+3)\to 4} = F_{(1+2+3)\to surr} = \frac{A_4}{A_{(1+2+3)}}(1) = \frac{\mathbf{a}}{\mathbf{a+2b}}$$

12-13 The view factors from the base of a cube to each of the other five surfaces are to be determined.

Assumptions The surfaces are diffuse emitters and reflectors.

Analysis Noting that $L_1 / w = L_2 / w = 1$, from Fig. 12-6 we read

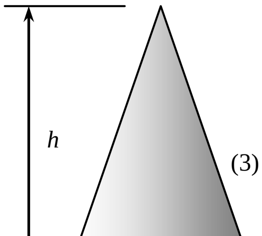


$$F_{12} = 0.2$$

Because of symmetry, we have

$$F_{12} = F_{13} = F_{14} = F_{15} = F_{16} = \mathbf{0.2}$$

12-14 The view factor from the conical side surface to a hole located at the center of the base of a conical enclosure is to be determined.



Assumptions The conical side surface is diffuse emitter and reflector.

Analysis We number different surfaces as

the hole located at the center of the base (1)
the base of conical enclosure (2)
conical side surface (3)

Surfaces 1 and 2 are flat , and they have no direct view of each other. Therefore,

$$F_{11} = F_{22} = F_{12} = F_{21} = 0$$

$$\text{summation rule: } F_{11} + F_{12} + F_{13} = 1 \longrightarrow F_{13} = 1$$

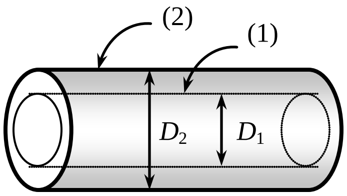
$$\text{reciprocity rule: } A_1 F_{13} = A_3 F_{31} \longrightarrow \frac{\pi d^2}{4}(1) = \frac{\pi D h}{2} F_{31} \longrightarrow F_{31} = \frac{d^2}{2Dh}$$

12-15 The four view factors associated with an enclosure formed by two very long concentric cylinders are to be determined.

Assumptions **1** The surfaces are diffuse emitters and reflectors. **2** End effects are neglected.

Analysis We number different surfaces as

the outer surface of the inner cylinder (1)
the inner surface of the outer cylinder (2)



No radiation leaving surface 1 strikes itself and thus $F_{11} = 0$

All radiation leaving surface 1 strikes surface 2 and thus $F_{12} = 1$

$$\text{reciprocity rule: } A_1 F_{12} = A_2 F_{21} \longrightarrow F_{21} = \frac{A_1}{A_2} F_{12} = \frac{\pi D_1 h}{\pi D_2 h}(1) = \frac{D_1}{D_2}$$

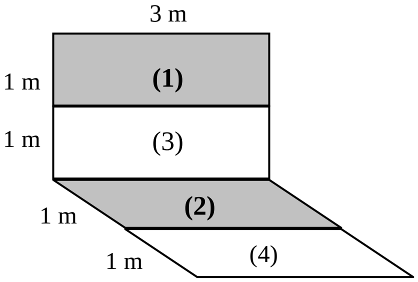
$$\text{summation rule: } F_{21} + F_{22} = 1 \longrightarrow F_{22} = 1 - F_{21} = 1 - \frac{D_1}{D_2}$$

12-16 The view factors between the rectangular surfaces shown in the figure are to be determined.

Assumptions The surfaces are diffuse emitters and reflectors.

Analysis We designate the different surfaces as follows:

shaded part of perpendicular surface by (1),
bottom part of perpendicular surface by (3),
shaded part of horizontal surface by (2), and
front part of horizontal surface by (4).



(*a*) From Fig.12-6

$$\left.\begin{array}{l}\dfrac{L_2}{W}=\dfrac{1}{3}\\[2ex] \dfrac{L_1}{W}=\dfrac{1}{3}\end{array}\right\}F_{23}=0.25 \quad \text{and} \quad \left.\begin{array}{l}\dfrac{L_2}{W}=\dfrac{2}{3}\\[2ex] \dfrac{L_1}{W}=\dfrac{1}{3}\end{array}\right\}F_{2\to(1+3)}=0.32$$

$$\text{superposition rule}: F_{2\to(1+3)}=F_{21}+F_{23}\longrightarrow F_{21}=F_{2\to(1+3)}-F_{23}=0.32-0.25=0.07$$

$$\text{reciprocity rule}: A_1=A_2\longrightarrow A_1F_{12}=A_2F_{21}\longrightarrow F_{12}=F_{21}=\mathbf{0.07}$$

(*b*) From Fig.12-6,

$$\frac{L_2}{W}=\frac{1}{3}\ \text{and}\ \left.\frac{L_1}{W}=\frac{2}{3}\right\}F_{(4+2)\to3}=0.15 \quad \text{and} \quad \frac{L_2}{W}=\frac{2}{3}\ \text{and}\ \left.\frac{L_1}{W}=\frac{2}{3}\right\}F_{(4+2)\to(1+3)}=0.22$$

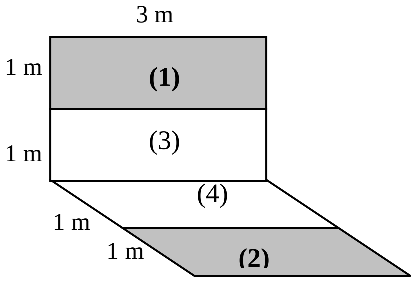
$$\text{superposition rule}: F_{(4+2)\to(1+3)}=F_{(4+2)\to1}+F_{(4+2)\to3}\longrightarrow F_{(4+2)\to1}=0.22-0.15=0.07$$

$$\text{reciprocity rule}: A_{(4+2)}F_{(4+2)\to1}=A_1F_{1\to(4+2)}$$

$$\longrightarrow F_{1\to(4+2)}=\frac{A_{(4+2)}}{A_1}F_{(4+2)\to1}=\frac{6}{3}(0.07)=0.14$$

$$\text{superposition rule}: F_{1\to(4+2)}=F_{14}+F_{12}$$

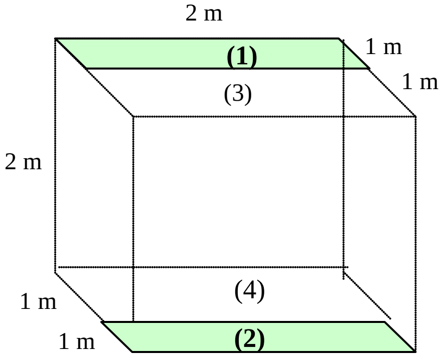
$$\longrightarrow F_{14}=0.14-0.07=\mathbf{0.07}$$



since F_{12} = 0.07 (from part *a*). Note that F_{14} in part (*b*) is equivalent to F_{12} in part (*a*).

(*c*) We designate

shaded part of top surface by (1),
remaining part of top surface by (3),
remaining part of bottom surface by (4), and
shaded part of bottom surface by (2).



From Fig.12-5,

$$\left.\begin{array}{l}\dfrac{L_2}{D}=\dfrac{2}{2}\\[2ex] \dfrac{L_1}{D}=\dfrac{2}{2}\end{array}\right\}F_{(2+4)\to(1+3)}=0.20 \quad \text{and} \quad \left.\begin{array}{l}\dfrac{L_2}{D}=\dfrac{2}{2}\\[2ex] \dfrac{L_1}{D}=\dfrac{1}{2}\end{array}\right\}F_{14}=0.12$$

$$\text{superposition rule}: F_{(2+4)\to(1+3)}=F_{(2+4)\to1}+F_{(2+4)\to3}$$

$$\text{symmetry rule}: F_{(2+4)\to1}=F_{(2+4)\to3}$$

Substituting symmetry rule gives

$$F_{(2+4)\to1}=F_{(2+4)\to3}=\frac{F_{(2+4)\to(1+3)}}{2}=\frac{0.20}{2}=0.10$$

$$\text{reciprocity rule}: A_1F_{1\to(2+4)}=A_{(2+4)}F_{(2+4)\to1}\longrightarrow(2)F_{1\to(2+4)}=(4)(0.10)\longrightarrow F_{1\to(2+4)}=0.20$$

$$\text{superposition rule}: F_{1\to(2+4)}=F_{12}+F_{14}\longrightarrow0.20=F_{12}+0.12\longrightarrow F_{12}=0.20-0.12=\mathbf{0.08}$$

12-17 The view factor between the two infinitely long parallel cylinders located a distance *s* apart from each other is to be determined.

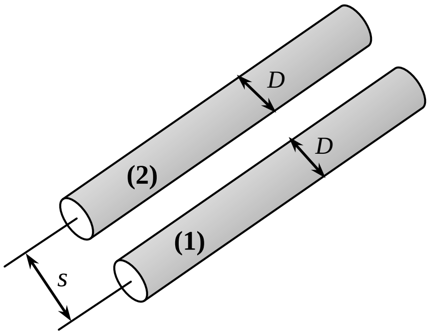
Assumptions The surfaces are diffuse emitters and reflectors.

Analysis Using the crossed-strings method, the view factor between two cylinders facing each other for *s/D* > 3 is determined to be

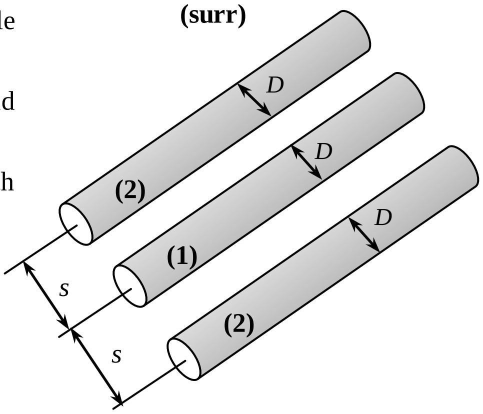
$$F_{1-2} = \frac{\sum \text{Crossed strings} - \sum \text{Uncrossed strings}}{2 \times \text{String on surface 1}}$$

$$= \frac{2\sqrt{s^2 + D^2} - 2s}{2(\pi D/2)}$$

or $$F_{1-2} = \frac{2\left(\sqrt{s^2 + D^2} - s\right)}{\pi D}$$



12-18 Three infinitely long cylinders are located parallel to each other. The view factor between the cylinder in the middle and the surroundings is to be determined.



Assumptions The cylinder surfaces are diffuse emitters and reflectors.

Analysis The view factor between two cylinder facing each other is, from Prob. 12-17,

$$F_{1-2} = \frac{2\left(\sqrt{s^2 + D^2} - s\right)}{\pi D}$$

Noting that the radiation leaving cylinder 1 that does not strike the cylinder will strike the surroundings, and this is also the case for the other half of the cylinder, the view factor between the cylinder in the middle and the surroundings becomes

$$F_{1-surr} = 1 - 2F_{1-2} = 1 - \frac{4\left(\sqrt{s^2 + D^2} - s\right)}{\pi D}$$

Radiation Heat Transfer Between Surfaces

12-19C The analysis of radiation exchange between black surfaces is relatively easy because of the absence of reflection. The rate of radiation heat transfer between two surfaces in this case is expressed as $\dot{Q} = A_1 F_{12} \sigma (T_1{}^4 - T_2{}^4)$ where A_1 is the surface area, F_{12} is the view factor, and T_1 and T_2 are the temperatures of two surfaces.

12-20C Radiosity is the total radiation energy leaving a surface per unit time and per unit area. Radiosity includes the emitted radiation energy as well as reflected energy. Radiosity and emitted energy are equal for blackbodies since a blackbody does not reflect any radiation.

12-21C Radiation surface resistance is given as $R_i = \dfrac{1-\varepsilon_i}{A_i \varepsilon_i}$ and it represents the resistance of a surface to the emission of radiation. It is zero for black surfaces. The space resistance is the radiation resistance between two surfaces and is expressed as $R_i = \dfrac{1-\varepsilon_i}{A_i \varepsilon_i}$

12-22C The two methods used in radiation analysis are the matrix and network methods. In matrix method, equations 12-34 and 12-35 give N linear algebraic equations for the determination of the N unknown radiosities for an N -surface enclosure. Once the radiosities are available, the unknown surface temperatures and heat transfer rates can be determined from these equations respectively. This method involves the use of matrices especially when there are a large number of surfaces. Therefore this method requires some knowledge of linear algebra.

The network method involves drawing a surface resistance associated with each surface of an enclosure and connecting them with space resistances. Then the radiation problem is solved by treating it as an electrical network problem where the radiation heat transfer replaces the current and the radiosity replaces the potential. The network method is not practical for enclosures with more than three or four surfaces due to the increased complexity of the network.

12-23C Some surfaces encountered in numerous practical heat transfer applications are modeled as being adiabatic as the back sides of these surfaces are well insulated and net heat transfer through these surfaces is zero. When the convection effects on the front (heat transfer) side of such a surface is negligible and steady-state conditions are reached, the surface must lose as much radiation energy as it receives. Such a surface is called reradiating surface. In radiation analysis, the surface resistance of a reradiating surface is taken to be zero since there is no heat transfer through it.

12-24E Top and side surfaces of a cubical furnace are black, and are maintained at uniform temperatures. Net radiation heat transfer rate to the base from the top and side surfaces are to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivities are given to be ε = 0.7 for the bottom surface and 1 for other surfaces.

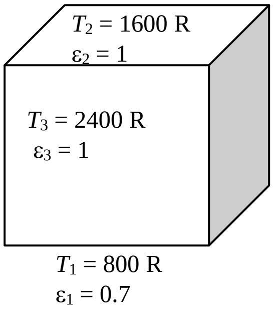
Analysis We consider the base surface to be surface 1, the top surface to be surface 2 and the side surfaces to be surface 3. The cubical furnace can be considered to be three-surface enclosure with a radiation network shown in the figure. The areas and blackbody emissive powers of surfaces are

$$A_1 = A_2 = (10\text{ ft})^2 = 100\text{ ft}^2 \qquad A_3 = 4(10\text{ ft})^2 = 400\text{ ft}^2$$

$$E_{b1} = \sigma T_1^{\ 4} = (0.1714\times10^{-8}\text{ Btu/h.ft}^2.\text{R}^4)(800\text{ R})^4 = 702\text{ Btu/h.ft}^2$$

$$E_{b2} = \sigma T_2^{\ 4} = (0.1714\times10^{-8}\text{ Btu/h.ft}^2.\text{R}^4)(1600\text{ R})^4 = 11{,}233\text{ Btu/h.ft}^2$$

$$E_{b3} = \sigma T_3^{\ 4} = (0.1714\times10^{-8}\text{ Btu/h.ft}^2.\text{R}^4)(2400\text{ R})^4 = 56{,}866\text{ Btu/h.ft}^2$$



The view factor from the base to the top surface of the cube is $F_{12} = 0.2$. From the summation rule, the view factor from the base or top to the side surfaces is

$$F_{11} + F_{12} + F_{13} = 1 \longrightarrow F_{13} = 1 - F_{12} = 1 - 0.2 = 0.8$$

since the base surface is flat and thus $F_{11} = 0$. Then the radiation resistances become

$$R_1 = \frac{1-\varepsilon_1}{A_1\varepsilon_1} = \frac{1-0.7}{(100\text{ ft}^2)(0.7)} = 0.0043\text{ ft}^{-2} \qquad R_{12} = \frac{1}{A_1F_{12}} = \frac{1}{(100\text{ ft}^2)(0.2)} = 0.0500\text{ ft}^{-2}$$

$$R_{13} = \frac{1}{A_1F_{13}} = \frac{1}{(100\text{ ft}^2)(0.8)} = 0.0125\text{ ft}^{-2}$$

Note that the side and the top surfaces are black, and thus their radiosities are equal to their emissive powers. The radiosity of the base surface is determined

$$\frac{E_{b1}-J_1}{R_1} + \frac{E_{b2}-J_1}{R_{12}} + \frac{E_{b3}-J_1}{R_{13}} = 0$$

Substituting, $$\frac{702-J_1}{0.0043} + \frac{11{,}233-J_1}{0.500} + \frac{56{,}866-J_1}{0.0125} = 0 \longrightarrow J_1 = 15{,}054\text{ W/m}^2$$

(*a*) The net rate of radiation heat transfer between the base and the side surfaces is

$$\dot{Q}_{31} = \frac{E_{b3}-J_1}{R_{13}} = \frac{(56{,}866-15{,}054)\text{ Btu/h.ft}^2}{0.0125\text{ ft}^{-2}} = \mathbf{3.345\times10^6\ Btu/h}$$

(*b*) The net rate of radiation heat transfer between the base and the top surfaces is

$$\dot{Q}_{12} = \frac{J_1-E_{b2}}{R_{12}} = \frac{(15{,}054-11{,}233)\text{ Btu/h.ft}^2}{0.05\text{ ft}^{-2}} = \mathbf{7.642\times10^4\ Btu/h}$$

The net rate of radiation heat transfer to the base surface is finally determined from

$$\dot{Q}_1 = \dot{Q}_{21} + \dot{Q}_{31} = -76{,}420 + 3{,}344{,}960 = \mathbf{3.269\times10^6\ Btu/h}$$

Discussion The same result can be found form

$$\dot{Q}_1 = \frac{J_1-E_{b1}}{R_1} = \frac{(15{,}054-702)\text{ Btu/h.ft}^2}{0.0043\text{ ft}^{-2}} = 3.338\times10^6\text{ Btu/h}$$

The small difference is due to round-off error.

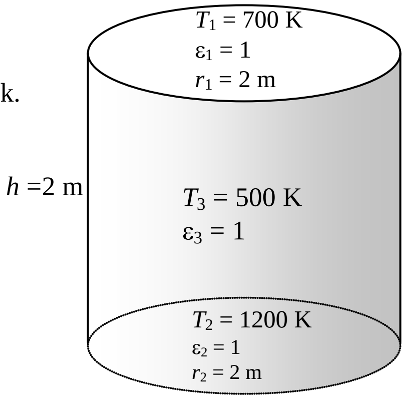
12-28 The base, top, and side surfaces of a furnace of cylindrical shape are black, and are maintained at uniform temperatures. The net rate of radiation heat transfer to or from the top surface is to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are black. **3** Convection heat transfer is not considered.



Properties The emissivity of all surfaces are ε = 1 since they are black.

Analysis We consider the top surface to be surface 1, the base surface to be surface 2 and the side surfaces to be surface 3. The cylindrical furnace can be considered to be three-surface enclosure. We assume that steady-state conditions exist. Since all surfaces are black, the radiosities are equal to the emissive power of surfaces, and the net rate of radiation heat transfer from the top surface can be determined from

$$\dot{Q} = A_1 F_{12}\sigma(T_1{}^4 - T_2{}^4) + A_1 F_{13}\sigma(T_1{}^4 - T_3{}^4)$$

and $A_1 = \pi r^2 = \pi(2\text{ m})^2 = 12.57\text{ m}^2$

The view factor from the base to the top surface of the cylinder is $F_{12} = 0.38$ (From Figure 12-44). The view factor from the base to the side surfaces is determined by applying the summation rule to be

$$F_{11} + F_{12} + F_{13} = 1 \longrightarrow F_{13} = 1 - F_{12} = 1 - 0.38 = 0.62$$

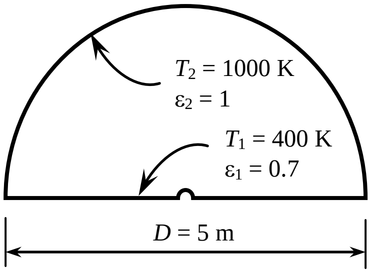
Substituting,

$$\begin{aligned}\dot{Q} &= A_1 F_{12}\sigma(T_1{}^4 - T_2{}^4) + A_1 F_{13}\sigma(T_1{}^4 - T_3{}^4)\\ &= (12.57\text{ m}^2)(0.38)(5.67\times10^{-8}\text{ W/m}^2.\text{K}^4)(700\text{ K}^4\text{ - }500\text{ K}^4)\\ &\quad + (12.57\text{ m}^2)(0.62)(5.67\times10^{-8}\text{ W/m}^2.\text{K}^4)(700\text{ K}^4\text{ - }1200\text{ K}^4)\\ &= -7.62\times10^5\text{ W} = \mathbf{-762\text{ kW}}\end{aligned}$$

Discussion The negative sign indicates that net heat transfer is to the top surface.

12-29 The base and the dome of a hemispherical furnace are maintained at uniform temperatures. The net rate of radiation heat transfer from the dome to the base surface is to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.



Analysis The view factor is first determined from

$$F_{11} = 0 \text{ (flat surface)}$$

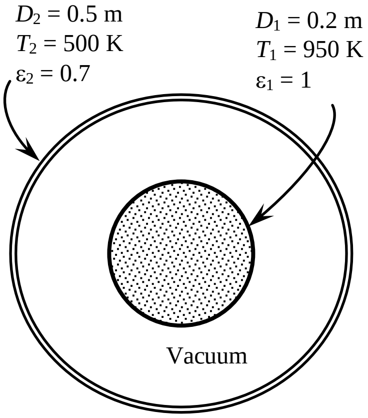
$$F_{11} + F_{12} = 1 \rightarrow F_{12} = 1 \text{ (summation rule)}$$

Noting that the dome is black, net rate of radiation heat transfer from dome to the base surface can be determined from

$$\begin{aligned}\dot{Q}_{21} &= -\dot{Q}_{12} = -\varepsilon A_1 F_{12}\sigma(T_1^{\,4} - T_2^{\,4})\\ &= -(0.7)[\pi(5\text{ m})^2/4](1)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[(400\text{ K})^4 - (1000\text{ K})^4]\\ &= 7.594\times10^5\text{ W}\\ &= \mathbf{759.4\ kW}\end{aligned}$$

The positive sign indicates that the net heat transfer is from the dome to the base surface, as expected.

12-30 Two very long concentric cylinders are maintained at uniform temperatures. The net rate of radiation heat transfer between the two cylinders is to be determined.



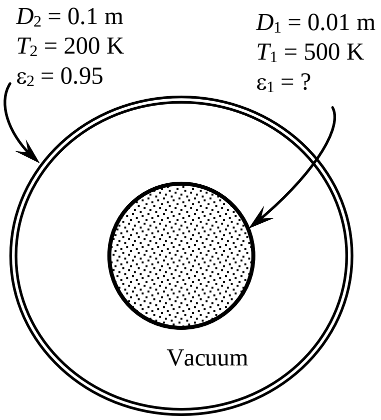
Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivities of surfaces are given to be $\varepsilon_1 = 1$ and $\varepsilon_2 = 0.7$.

Analysis The net rate of radiation heat transfer between the two cylinders per unit length of the cylinders is determined from

$$\begin{aligned}\dot{Q}_{12} &= \frac{A_1\sigma(T_1^{\,4} - T_2^{\,4})}{\dfrac{1}{\varepsilon_1} + \dfrac{1-\varepsilon_2}{\varepsilon_2}\left(\dfrac{r_1}{r_2}\right)} = \frac{[\pi(0.2\text{ m})(1\text{m})](5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[(950\text{ K})^4 - (500\text{ K})^4]}{\dfrac{1}{1} + \dfrac{1-0.7}{0.7}\left(\dfrac{2}{5}\right)}\\ &= 22{,}870\text{ W} = \mathbf{22.87\ kW}\end{aligned}$$

12-31 A long cylindrical rod coated with a new material is placed in an evacuated long cylindrical enclosure which is maintained at a uniform temperature. The emissivity of the coating on the rod is to be determined.



Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray.

Properties The emissivity of the enclosure is given to be ε_2 = 0.95.

Analysis The emissivity of the coating on the rod is determined from

$$\dot{Q}_{12} = \frac{A_1\sigma(T_1^{\,4} - T_2^{\,4})}{\dfrac{1}{\varepsilon_1} + \dfrac{1-\varepsilon_2}{\varepsilon_2}\left(\dfrac{r_1}{r_2}\right)}$$

$$8\text{ W} = \frac{[\pi(0.01\text{ m})(1\text{ m})](5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[(500\text{ K})^4 - (200\text{ K})^4]}{\dfrac{1}{\varepsilon_1} + \dfrac{1-0.95}{0.95}\left(\dfrac{1}{10}\right)}$$

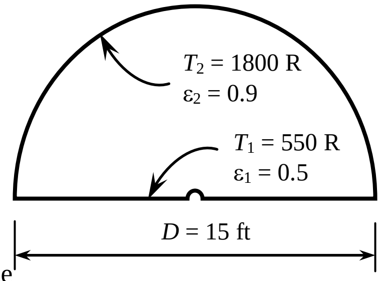
which gives

ε_1 = **0.074**

12-32E The base and the dome of a long semicylindrical duct are maintained at uniform temperatures. The net rate of radiation heat transfer from the dome to the base surface is to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivities of surfaces are given to be ε_1 = 0.5 and ε_2 = 0.9.



Analysis The view factor from the base to the dome is first determined from

$$F_{11} = 0 \text{ (flat surface)}$$
$$F_{11} + F_{12} = 1 \rightarrow F_{12} = 1 \text{ (summation rule)}$$

The net rate of radiation heat transfer from dome to the base surface can be determined from

$$\dot{Q}_{21} = -\dot{Q}_{12} = -\frac{\sigma(T_1^{\,4} - T_2^{\,4})}{\dfrac{1-\varepsilon_1}{A_1\varepsilon_1} + \dfrac{1}{A_1F_{12}} + \dfrac{1-\varepsilon_2}{A_2\varepsilon_2}} = -\frac{(0.1714\times10^{-8}\text{ Btu/h.ft}^2\cdot\text{R}^4)[(550\text{ R})^4 - (1800\text{ R})^4]}{\dfrac{1-0.5}{(15\text{ ft}^2)(0.5)} + \dfrac{1}{(15\text{ ft}^2)(1)} + \dfrac{1-0.9}{\left[\dfrac{\pi(15\text{ ft})(1\text{ ft})}{2}\right](0.9)}}$$

$$= \mathbf{1.311\times10^6\ Btu/h}$$

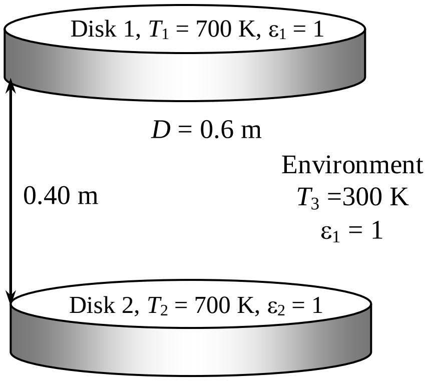
The positive sign indicates that the net heat transfer is from the dome to the base surface, as expected.

12-33 Two parallel disks whose back sides are insulated are black, and are maintained at a uniform temperature. The net rate of radiation heat transfer from the disks to the environment is to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivities of all surfaces are ε = 1 since they are black.

Analysis Both disks possess same properties and they are black. Noting that environment can also be considered to be blackbody, we can treat this geometry as a three surface enclosure. We consider the two disks to be surfaces 1 and 2 and the environment to be surface 3. Then from Figure 12-7, we read



Disk 1, T_1 = 700 K, ε_1 = 1
D = 0.6 m
Environment
T_3 =300 K
ε_1 = 1
0.40 m
Disk 2, T_2 = 700 K, ε_2 = 1

$$F_{12} = F_{21} = 0.26$$
$$F_{13} = 1 - 0.26 = 0.74 \quad \text{(summation rule)}$$

The net rate of radiation heat transfer from the disks into the environment then becomes

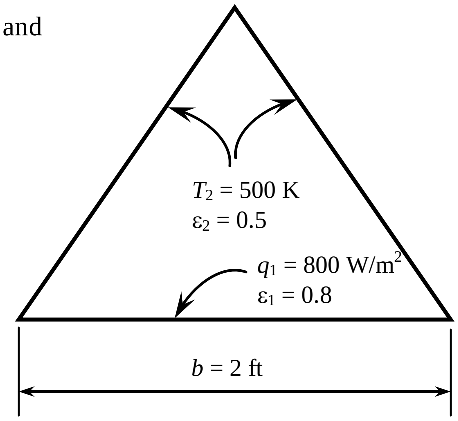
$$\dot{Q}_3 = \dot{Q}_{13} + \dot{Q}_{23} = 2\dot{Q}_{13}$$
$$\begin{aligned}\dot{Q}_3 &= 2F_{13}A_1\sigma(T_1^{\,4} - T_3^{\,4})\\ &= 2(0.74)[\pi(0.3\,\text{m})^2](5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(700\ \text{K})^4 - (300\ \text{K})^4]\\ &= \mathbf{5505\ W}\end{aligned}$$

12-34 A furnace shaped like a long equilateral-triangular duct is considered. The temperature of the base surface is to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered. **4** End effects are neglected.

Properties The emissivities of surfaces are given to be ε_1 = 0.8 and ε_2 = 0.5.

Analysis This geometry can be treated as a two surface enclosure since two surfaces have identical properties. We consider base surface to be surface 1 and other two surface to be surface 2. Then the view factor between the two becomes $F_{12} = 1$. The temperature of the base surface is determined from



$$\dot{Q}_{12} = \frac{\sigma(T_1^{\,4} - T_2^{\,4})}{\dfrac{1-\varepsilon_1}{A_1\varepsilon_1} + \dfrac{1}{A_1F_{12}} + \dfrac{1-\varepsilon_2}{A_2\varepsilon_2}}$$

$$800\ \text{W} = \frac{(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(T_1)^4 - (500\ \text{K})^4]}{\dfrac{1-0.8}{(1\,\text{m}^2)(0.8)} + \dfrac{1}{(1\,\text{m}^2)(1)} + \dfrac{1-0.5}{(2\,\text{m}^2)(0.5)}} \longrightarrow \mathbf{T_1 = 543\ K}$$

Note that $A_1 = 1\,\text{m}^2$ and $A_2 = 2\,\text{m}^2$.

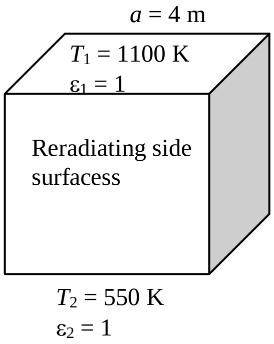
12-36 The floor and the ceiling of a cubical furnace are maintained at uniform temperatures. The net rate of radiation heat transfer between the floor and the ceiling is to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivities of all surfaces are $\varepsilon = 1$ since they are black or reradiating.

Analysis We consider the ceiling to be surface 1, the floor to be surface 2 and the side surfaces to be surface 3. The furnace can be considered to be three-surface enclosure with a radiation network shown in the figure. We assume that steady-state conditions exist. Since the side surfaces are reradiating, there is no heat transfer through them, and the entire heat lost by the ceiling must be gained by the floor. The view factor from the ceiling to the floor of the furnace is $F_{12} = 0.2$. Then the rate of heat loss from the ceiling can be determined from

$$\dot{Q}_1 = \frac{E_{b1} - E_{b2}}{\left(\dfrac{1}{R_{12}} + \dfrac{1}{R_{13} + R_{23}}\right)^{-1}}$$



where

$$E_{b1} = \sigma T_1^{\,4} = (5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)(1100\ \text{K})^4 = 83{,}015\ \text{W/m}^2$$

$$E_{b2} = \sigma T_2^{\,4} = (5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)(550\ \text{K})^4 = 5188\ \text{W/m}^2$$

and

$$A_1 = A_2 = (4\ \text{m})^2 = 16\ \text{m}^2$$

$$R_{12} = \frac{1}{A_1F_{12}} = \frac{1}{(16\ \text{m}^2)(0.2)} = 0.3125\ \text{m}^{-2}$$

$$R_{13} = R_{23} = \frac{1}{A_1F_{13}} = \frac{1}{(16\ \text{m}^2)(0.8)} = 0.078125\ \text{m}^{-2}$$

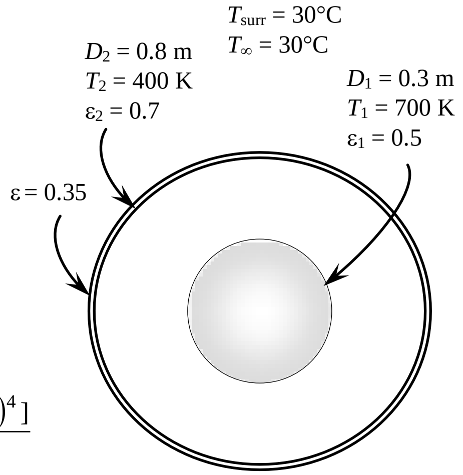
Substituting,

$$\dot{Q}_{12} = \frac{(83{,}015 - 5188)\ \text{W/m}^2}{\left(\dfrac{1}{0.3125\ \text{m}^{-2}} + \dfrac{1}{2(0.078125\ \text{m}^{-2})}\right)^{-1}} = 7.47\times10^5\ \text{W} = \mathbf{747\ kW}$$

12-37 Two concentric spheres are maintained at uniform temperatures. The net rate of radiation heat transfer between the two spheres and the convection heat transfer coefficient at the outer surface are to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray.

Properties The emissivities of surfaces are given to be $\varepsilon_1 = 0.1$ and $\varepsilon_2 = 0.8$.



Analysis The net rate of radiation heat transfer between the two spheres is

$$\dot{Q}_{12} = \frac{A_1\sigma(T_1^4 - T_2^4)}{\dfrac{1}{\varepsilon_1} + \dfrac{1-\varepsilon_2}{\varepsilon_2}\left(\dfrac{r_1^2}{r_2^2}\right)}$$

$$= \frac{[\pi(0.3\,\text{m})^2](5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(700\,\text{K})^4 - (400\,\text{K})^4]}{\dfrac{1}{0.5} + \dfrac{1-0.7}{0.7}\left(\dfrac{0.15\,\text{m}}{0.4\,\text{m}}\right)^2}$$

$$= \mathbf{1669\ W}$$

Radiation heat transfer rate from the outer sphere to the surrounding surfaces are

$$\dot{Q}_{rad} = \varepsilon F A_2 \sigma(T_2^4 - T_{surr}^4)$$
$$= (0.35)(1)[\pi(0.8\,\text{m})^2](5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(400\,\text{K})^4 - (30+273\,\text{K})^4] = 685\ \text{W}$$

The convection heat transfer rate at the outer surface of the cylinder is determined from requirement that heat transferred from the inner sphere to the outer sphere must be equal to the heat transfer from the outer surface of the outer sphere to the environment by convection and radiation. That is,

$$\dot{Q}_{conv} = \dot{Q}_{12} - \dot{Q}_{rad} = 1669 - 685 = 9845\ \text{W}$$

Then the convection heat transfer coefficient becomes

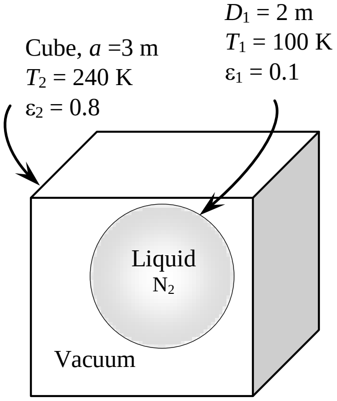
$$\dot{Q}_{conv.} = hA_2(T_2 - T_\infty)$$
$$984\ \text{W} = h\left[\pi(0.8\,\text{m})^2\right](400\ \text{K} - 303\ \text{K}) \longrightarrow h = \mathbf{5.04\ W/m^2\cdot{}^\circ C}$$

12-38 A spherical tank filled with liquid nitrogen is kept in an evacuated cubic enclosure. The net rate of radiation heat transfer to the liquid nitrogen is to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered. **4** The thermal resistance of the tank is negligible.

Properties The emissivities of surfaces are given to be $\varepsilon_1 = 0.1$ and $\varepsilon_2 = 0.8$.

Analysis We take the sphere to be surface 1 and the surrounding cubic enclosure to be surface 2. Noting that $F_{12} = 1$, for this two-surface enclosure, the net rate of radiation heat transfer to liquid nitrogen can be determined from



$$\dot{Q}_{21} = -\dot{Q}_{12} = -\frac{A_1\sigma\left(T_1^{\,4} - T_2^{\,4}\right)}{\dfrac{1}{\varepsilon_1} + \dfrac{1-\varepsilon_2}{\varepsilon_2}\left(\dfrac{A_1}{A_2}\right)}$$

$$= -\frac{\left[\pi(2\text{ m})^2\right]\left(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4\right)\left[(100\text{ K})^4 - (240\text{ K})^4\right]}{\dfrac{1}{0.1} + \dfrac{1-0.8}{0.8}\left[\dfrac{\pi(2\text{ m})^2}{6(3\text{ m})^2}\right]}$$

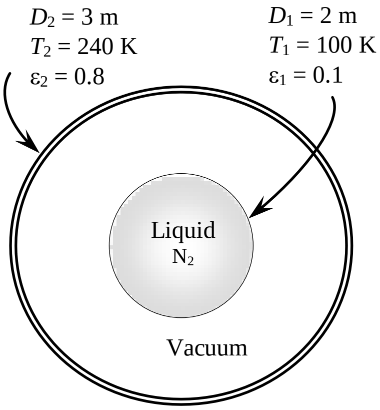
$$= \textbf{228 W}$$

12-39 A spherical tank filled with liquid nitrogen is kept in an evacuated spherical enclosure. The net rate of radiation heat transfer to the liquid nitrogen is to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered. **4** The thermal resistance of the tank is negligible.

Properties The emissivities of surfaces are given to be $\varepsilon_1 = 0.1$ and $\varepsilon_2 = 0.8$.

Analysis The net rate of radiation heat transfer to liquid nitrogen can be determined from



$$\dot{Q}_{12} = \frac{A_1\sigma(T_1^{\,4} - T_2^{\,4})}{\dfrac{1}{\varepsilon_1} + \dfrac{1-\varepsilon_2}{\varepsilon_2}\left(\dfrac{r_1^{\,2}}{r_2^{\,2}}\right)}$$

$$= \frac{[\pi(2\text{ m})^2](5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[(240\text{ K})^4 - (100\text{ K})^4]}{\dfrac{1}{0.1} + \dfrac{1-0.8}{0.8}\left(\dfrac{(1\text{ m})^2}{(1.5\text{ m})^2}\right)}$$

$$= \textbf{227 W}$$

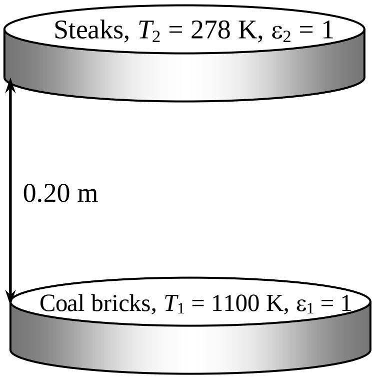
12-41 A circular grill is considered. The bottom of the grill is covered with hot coal bricks, while the wire mesh on top of the grill is covered with steaks. The initial rate of radiation heat transfer from coal bricks to the steaks is to be determined for two cases.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivities are $\varepsilon = 1$ for all surfaces since they are black or reradiating.



Steaks, T_2 = 278 K, ε_2 = 1
0.20 m
Coal bricks, T_1 = 1100 K, ε_1 = 1

Analysis We consider the coal bricks to be surface 1, the steaks to be surface 2 and the side surfaces to be surface 3. First we determine the view factor between the bricks and the steaks (Table 12-1),

$$R_i = R_j = \frac{r_i}{L} = \frac{0.15\text{ m}}{0.20\text{ m}} = 0.75$$

$$S = 1 + \frac{1 + R_j^{\,2}}{R_i^{\,2}} = \frac{1 + 0.75^2}{0.75^2} = 3.7778$$

$$F_{12} = F_{ij} = \frac{1}{2}\left\{S - \left[S^2 - 4\left(\frac{R_j}{R_i}\right)^2\right]^{1/2}\right\} = \frac{1}{2}\left\{3.7778 - \left[3.7778^2 - 4\left(\frac{0.75}{0.75}\right)^2\right]^{1/2}\right\} = 0.2864$$

(It can also be determined from Fig. 12-7).

Then the initial rate of radiation heat transfer from the coal bricks to the stakes becomes

$$\begin{aligned}\dot{Q}_{12} &= F_{12}A_1\sigma(T_1^{\,4} - T_2^{\,4})\\ &= (0.2864)[\pi(0.3\text{ m})^2/4](5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[(1100\text{ K})^4 - (278\text{ K})^4]\\ &= \mathbf{1674\ W}\end{aligned}$$

When the side opening is closed with aluminum foil, the entire heat lost by the coal bricks must be gained by the stakes since there will be no heat transfer through a reradiating surface. The grill can be considered to be three-surface enclosure. Then the rate of heat loss from the room can be determined from

$$\dot{Q}_1 = \frac{E_{b1} - E_{b2}}{\left(\dfrac{1}{R_{12}} + \dfrac{1}{R_{13} + R_{23}}\right)^{-1}}$$

where
$$E_{b1} = \sigma T_1^{\,4} = (5.67\times10^{-8}\text{ W/m}^2.\text{K}^4)(1100\text{ K})^4 = 83{,}015\text{ W/m}^2$$
$$E_{b2} = \sigma T_2^{\,4} = (5.67\times10^{-8}\text{ W/m}^2.\text{K}^4)(18 + 273\text{ K})^4 = 407\text{ W/m}^2$$

and
$$A_1 = A_2 = \frac{\pi(0.3\text{ m})^2}{4} = 0.07069\text{ m}^2$$

$$R_{12} = \frac{1}{A_1F_{12}} = \frac{1}{(0.07069\text{ m}^2)(0.2864)} = 49.39\text{ m}^{-2}$$

$$R_{13} = R_{23} = \frac{1}{A_1F_{13}} = \frac{1}{(0.07069\text{ m}^2)(1 - 0.2864)} = 19.82\text{ m}^{-2}$$

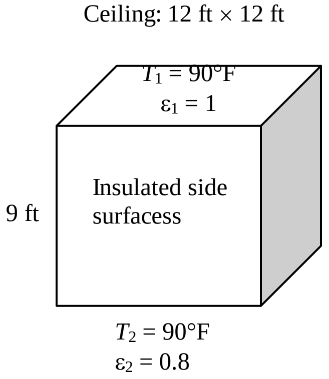
Substituting,
$$\dot{Q}_{12} = \frac{(83{,}015 - 407)\text{ W/m}^2}{\left(\dfrac{1}{49.39\text{ m}^{-2}} + \dfrac{1}{2(19.82\text{ m}^{-2})}\right)^{-1}} = \mathbf{3757\ W}$$

12-42E A room is heated by lectric resistance heaters placed on the ceiling which is maintained at a uniform temperature. The rate of heat loss from the room through the floor is to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered. **4** There is no heat loss through the side surfaces.

Properties The emissivities are ε = 1 for the ceiling and ε = 0.8 for the floor. The emissivity of insulated (or reradiating) surfaces is also 1.

Analysis The room can be considered to be three-surface enclosure with the ceiling surface 1, the floor surface 2 and the side surfaces surface 3. We assume steady-state conditions exist. Since the side surfaces are reradiating, there is no heat transfer through them, and the entire heat lost by the ceiling must be gained by the floor. Then the rate of heat loss from the room through its floor can be determined from



$$\dot{Q}_1 = \frac{E_{b1} - E_{b2}}{\left(\dfrac{1}{R_{12}} + \dfrac{1}{R_{13} + R_{23}}\right)^{-1} + R_2}$$

where

$$E_{b1} = \sigma T_1^{\,4} = (0.1714\times10^{-8}\ \text{Btu/h.ft}^2.\text{R}^4)(90 + 460\ \text{R})^4 = 157\ \text{Btu/h.ft}^2$$

$$E_{b2} = \sigma T_2^{\,4} = (0.1714\times10^{-8}\ \text{Btu/h.ft}^2.\text{R}^4)(65 + 460\ \text{R})^4 = 130\ \text{Btu/h.ft}^2$$

and

$$A_1 = A_2 = (12\ \text{ft})^2 = 144\ \text{ft}^2$$

The view factor from the floor to the ceiling of the room is $F_{12} = 0.27$ (From Figure 12-42). The view factor from the ceiling or the floor to the side surfaces is determined by applying the summation rule to be

$$F_{11} + F_{12} + F_{13} = 1 \longrightarrow F_{13} = 1 - F_{12} = 1 - 0.27 = 0.73$$

since the ceiling is flat and thus $F_{11} = 0$. Then the radiation resistances which appear in the equation above become

$$R_2 = \frac{1-\varepsilon_2}{A_2\varepsilon_2} = \frac{1-0.8}{(144\ \text{ft}^2)(0.8)} = 0.00174\ \text{ft}^{-2}$$

$$R_{12} = \frac{1}{A_1 F_{12}} = \frac{1}{(144\ \text{ft}^2)(0.27)} = 0.02572\ \text{ft}^{-2}$$

$$R_{13} = R_{23} = \frac{1}{A_1 F_{13}} = \frac{1}{(144\ \text{ft}^2)(0.73)} = 0.009513\ \text{ft}^{-2}$$

Substituting,

$$\dot{Q}_{12} = \frac{(157-130)\ \text{Btu/h.ft}^2}{\left(\dfrac{1}{0.02572\ \text{ft}^{-2}} + \dfrac{1}{2(0.009513\ \text{ft}^{-2})}\right)^{-1} + 0.00174\ \text{ft}^{-2}} = \mathbf{2130\ Btu/h}$$

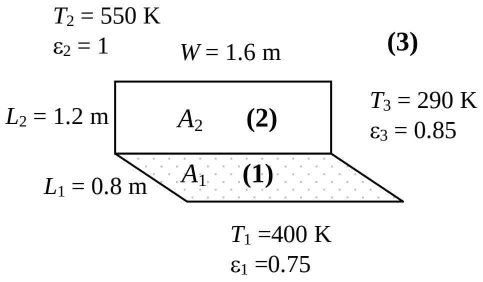
12-43 Two perpendicular rectangular surfaces with a common edge are maintained at specified temperatures. The net rate of radiation heat transfers between the two surfaces and between the horizontal surface and the surroundings are to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivities of the horizontal rectangle and the surroundings are ε = 0.75 and ε = 0.85, respectively.

Analysis We consider the horizontal rectangle to be surface 1, the vertical rectangle to be surface 2 and the surroundings to be surface 3. This system can be considered to be a three-surface enclosure. The view factor from surface 1 to surface 2 is determined from

$$\left.\begin{aligned}\frac{L_1}{W}&=\frac{0.8}{1.6}=0.5\\ \frac{L_2}{W}&=\frac{1.2}{1.6}=0.75\end{aligned}\right\}F_{12}=0.27 \qquad \text{(Fig. 12-6)}$$



The surface areas are

$$A_1=(0.8\text{ m})(1.6\text{ m})=1.28\text{ m}^2$$

$$A_2=(1.2\text{ m})(1.6\text{ m})=1.92\text{ m}^2$$

$$A_3=2\times\frac{1.2\times0.8}{2}+\sqrt{0.8^2+1.2^2}\times1.6=3.268\text{ m}^2$$

Note that the surface area of the surroundings is determined assuming that surroundings forms flat surfaces at all openings to form an enclosure. Then other view factors are determined to be

$$A_1F_{12}=A_2F_{21}\longrightarrow(1.28)(0.27)=(1.92)F_{21}\longrightarrow F_{21}=0.18 \qquad \text{(reciprocity rule)}$$

$$F_{11}+F_{12}+F_{13}=1\longrightarrow0+0.27+F_{13}=1\longrightarrow F_{13}=0.73 \qquad \text{(summation rule)}$$

$$F_{21}+F_{22}+F_{23}=1\longrightarrow0.18+0+F_{23}=1\longrightarrow F_{23}=0.82 \qquad \text{(summation rule)}$$

$$A_1F_{13}=A_3F_{31}\longrightarrow(1.28)(0.73)=(3.268)F_{31}\longrightarrow F_{31}=0.29 \qquad \text{(reciprocity rule)}$$

$$A_2F_{23}=A_3F_{32}\longrightarrow(1.92)(0.82)=(3.268)F_{32}\longrightarrow F_{32}=0.48 \qquad \text{(reciprocity rule)}$$

We now apply Eq. 9-52b to each surface to determine the radiosities.

Surface 1:

$$\sigma T_1^{\,4}=J_1+\frac{1-\varepsilon_1}{\varepsilon_1}\left[F_{12}(J_1-J_2)+F_{13}(J_1-J_3)\right]$$

$$(5.67\times10^{-8}\text{ W/m}^2.\text{K}^4)(400\text{ K})^4=J_1+\frac{1-0.75}{0.75}\left[0.27(J_1-J_2)+0.73(J_1-J_3)\right]$$

Surface 2:

$$\sigma T_2^{\,4}=J_2\longrightarrow(5.67\times10^{-8}\text{ W/m}^2.\text{K}^4)(550\text{ K})^4=J_2$$

Surface 3:

$$\sigma T_3^{\,4}=J_3+\frac{1-\varepsilon_3}{\varepsilon_3}\left[F_{31}(J_3-J_1)+F_{32}(J_3-J_2)\right]$$

$$(5.67\times10^{-8}\text{ W/m}^2.\text{K}^4)(290\text{ K})^4=J_3+\frac{1-0.85}{0.85}\left[0.29(J_1-J_2)+0.48(J_1-J_3)\right]$$

Solving the above equations, we find

$$J_1=1587\text{ W/m}^2,\quad J_2=5188\text{ W/m}^2,\quad J_3=811.5\text{ W/m}^2$$

Then the net rate of radiation heat transfers between the two surfaces and between the horizontal surface and the surroundings are determined to be

$$\dot{Q}_{21}=-\dot{Q}_{12}=-A_1F_{12}(J_1-J_2)=-(1.28\text{ m}^2)(0.27)(1587-5188)\text{W/m}^2=\mathbf{1245\ W}$$

$$\dot{Q}_{13}=A_1F_{13}(J_1-J_3)=(1.28\text{ m}^2)(0.73)(1587-811.5)\text{W/m}^2=\mathbf{725\ W}$$

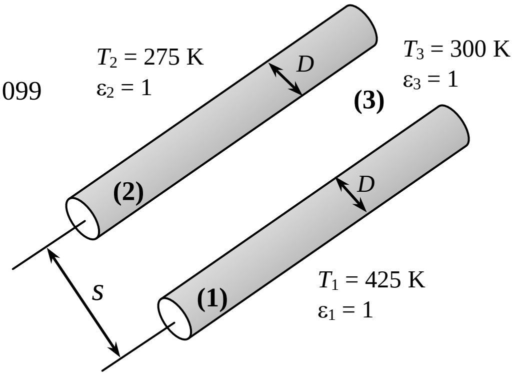
12-44 Two long parallel cylinders are maintained at specified temperatures. The rates of radiation heat transfer between the cylinders and between the hot cylinder and the surroundings are to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are black. **3** Convection heat transfer is not considered.

Analysis We consider the hot cylinder to be surface 1, cold cylinder to be surface 2, and the surroundings to be surface 3. Using the crossed-strings method, the view factor between two cylinders facing each other is determined to be

$$F_{1-2} = \frac{\sum \text{Crossed strings} - \sum \text{Uncrossed strings}}{2 \times \text{String on surface 1}} = \frac{2\sqrt{s^2+D^2} - 2s}{2(\pi D/2)}$$

or
$$F_{1-2} = \frac{2\left(\sqrt{s^2+D^2} - s\right)}{\pi D} = \frac{2\left(\sqrt{0.5^2+0.16^2} - 0.5\right)}{\pi(0.16)} = 0.099$$



The view factor between the hot cylinder and the surroundings is

$$F_{13} = 1 - F_{12} = 1 - 0.099 = 0.901 \text{ (summation rule)}$$

The rate of radiation heat transfer between the cylinders per meter length is

$$A = \pi DL/2 = \pi(0.16\text{ m})(1\text{ m})/2 = 0.2513\text{ m}^2$$

$$\dot{Q}_{12} = AF_{12}\sigma(T_1^4 - T_2^4) = (0.2513\text{ m}^2)(0.099)(5.67\times10^{-8}\text{ W/m}^2.°\text{C})(425^4 - 275^4)\text{K}^4 = \mathbf{38.0\ W}$$

Note that half of the surface area of the cylinder is used, which is the only area that faces the other cylinder. The rate of radiation heat transfer between the hot cylinder and the surroundings per meter length of the cylinder is

$$A_1 = \pi DL = \pi(0.16\text{ m})(1\text{ m}) = 0.5027\text{ m}^2$$

$$\dot{Q}_{13} = A_1F_{13}\sigma(T_1^4 - T_3^4) = (0.5027\text{ m}^2)(0.901)(5.67\times10^{-8}\text{ W/m}^2.°\text{C})(425^4 - 300^4)\text{K}^4 = \mathbf{629.8\ W}$$

12-45 A long semi-cylindrical duct with specified temperature on the side surface is considered. The temperature of the base surface for a specified heat transfer rate is to be determined.

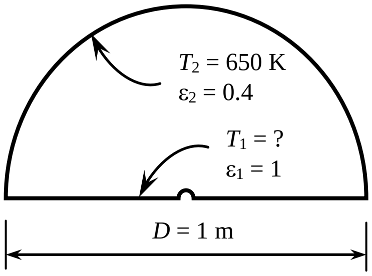
Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivity of the side surface is ε = 0.4.

Analysis We consider the base surface to be surface 1, the side surface to be surface 2. This system is a two-surface enclosure, and we consider a unit length of the duct. The surface areas and the view factor are determined as

$$A_1 = (1.0\text{ m})(1.0\text{ m}) = 1.0\text{ m}^2$$

$$A_2 = \pi DL/2 = \pi(1.0\text{ m})(1\text{ m})/2 = 1.571\text{ m}^2$$



$$F_{11} + F_{12} = 1 \longrightarrow 0 + F_{12} = 1 \longrightarrow F_{12} = 1 \quad \text{(summation rule)}$$

The temperature of the base surface is determined from

$$\dot{Q}_{12} = \frac{\sigma(T_1^4 - T_2^4)}{\dfrac{1}{A_1F_{12}} + \dfrac{1-\varepsilon_2}{A_2\varepsilon_2}}$$

$$1200\text{ W} = \frac{(5.67\times10^{-8}\text{ W/m}^2\cdot K^4)[T_1^4 - (650\text{ K})^4]}{\dfrac{1}{(1.0\text{ m}^2)(1)} + \dfrac{1-0.4}{(1.571\text{ m}^2)(0.4)}} \longrightarrow T_1 = \mathbf{684.8\ K}$$

12-46 A hemisphere with specified base and dome temperatures and heat transfer rate is considered. The emissivity of the dome is to be determined.

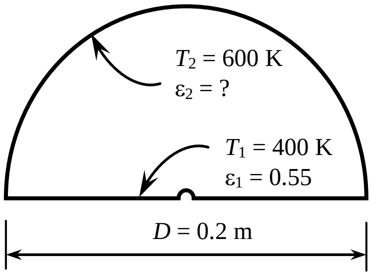
Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivity of the base surface is ε = 0.55.

Analysis We consider the base surface to be surface 1, the dome surface to be surface 2. This system is a two-surface enclosure. The surface areas and the view factor are determined as

$$A_1 = \pi D^2/4 = \pi(0.2\text{ m})^2/4 = 0.0314\text{ m}^2$$

$$A_2 = \pi D^2/2 = \pi(0.2\text{ m})^2/2 = 0.0628\text{ m}^2$$



$$F_{11} + F_{12} = 1 \longrightarrow 0 + F_{12} = 1 \longrightarrow F_{12} = 1 \quad \text{(summation rule)}$$

The emissivity of the dome is determined from

$$\dot{Q}_{21} = -\dot{Q}_{12} = -\frac{\sigma(T_1^4 - T_2^4)}{\dfrac{1-\varepsilon_1}{A_1\varepsilon_1} + \dfrac{1}{A_1F_{12}} + \dfrac{1-\varepsilon_2}{A_2\varepsilon_2}}$$

$$50\text{ W} = -\frac{(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[(400\text{ K})^4 - (600\text{ K})^4]}{\dfrac{1-0.55}{(0.0314\text{ m}^2)(0.55)} + \dfrac{1}{(0.0314\text{ m}^2)(1)} + \dfrac{1-\varepsilon_2}{(0.0628\text{ m}^2)\varepsilon_2}} \longrightarrow \varepsilon_2 = \mathbf{0.21}$$

Radiation Shields and The Radiation Effect

12-47C Radiation heat transfer between two surfaces can be reduced greatly by inserting a thin, high reflectivity(low emissivity) sheet of material between the two surfaces. Such highly reflective thin plates or shells are known as radiation shields. Multilayer radiation shields constructed of about 20 shields per cm. thickness separated by evacuated space are commonly used in cryogenic and space applications to minimize heat transfer. Radiation shields are also used in temperature measurements of fluids to reduce the error caused by the radiation effect.

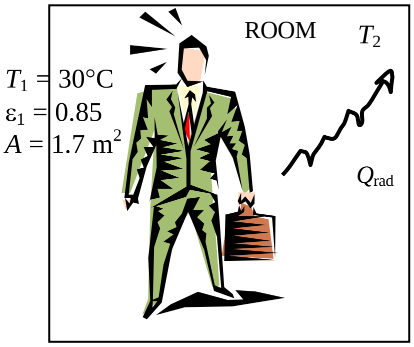
12-48C The influence of radiation on heat transfer or temperature of a surface is called the radiation effect. The radiation exchange between the sensor and the surroundings may cause the thermometer to indicate a different reading for the medium temperature. To minimize the radiation effect, the sensor should be coated with a material of high reflectivity (low emissivity).

12-49C A person who feels fine in a room at a specified temperature may feel chilly in another room at the same temperature as a result of radiation effect if the walls of second room are at a considerably lower temperature. For example most people feel comfortable in a room at 22°C if the walls of the room are also roughly at that temperature. When the wall temperature drops to 5°C for some reason, the interior temperature of the room must be raised to at least 27°C to maintain the same level of comfort. Also, people sitting near the windows of a room in winter will feel colder because of the radiation exchange between the person and the cold windows.

12-50 The rate of heat loss from a person by radiation in a large room whose walls are maintained at a uniform temperature is to be determined for two cases.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivity of the person is given to be $\varepsilon_1 = 0.7$.



Analysis (*a*) Noting that the view factor from the person to the walls $F_{12} = 1$, the rate of heat loss from that person to the walls at a large room which are at a temperature of 300 K is

$$\begin{aligned}\dot{Q}_{12} &= \varepsilon_1 F_{12} A_1 \sigma (T_1^{\,4} - T_2^{\,4}) \\ &= (0.85)(1)(1.7\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(303\ \text{K})^4 - (300\ \text{K})^4] \\ &= \mathbf{26.9\ W}\end{aligned}$$

(*b*) When the walls are at a temperature of 280 K,

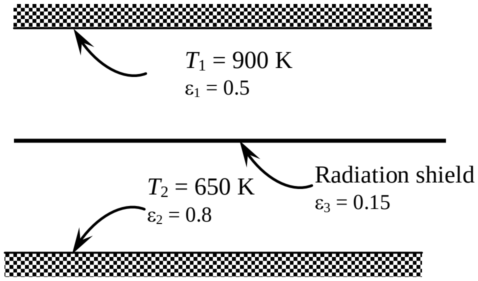
$$\begin{aligned}\dot{Q}_{12} &= \varepsilon_1 F_{12} A_1 \sigma (T_1^{\,4} - T_2^{\,4}) \\ &= (0.85)(1)(1.7\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(303\ \text{K})^4 - (280\ \text{K})^4] \\ &= \mathbf{187\ W}\end{aligned}$$

12-51 A thin aluminum sheet is placed between two very large parallel plates that are maintained at uniform temperatures. The net rate of radiation heat transfer between the two plates is to be determined for the cases of with and without the shield.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivities of surfaces are given to be $\varepsilon_1 = 0.5$, $\varepsilon_2 = 0.8$, and $\varepsilon_3 = 0.15$.

Analysis The net rate of radiation heat transfer with a thin aluminum shield per unit area of the plates is



$$\dot{Q}_{12,\text{one shield}} = \frac{\sigma(T_1^4 - T_2^4)}{\left(\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1\right) + \left(\frac{1}{\varepsilon_{3,1}} + \frac{1}{\varepsilon_{3,2}} - 1\right)}$$

$$= \frac{(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(900\ \text{K})^4 - (650\ \text{K})^4]}{\left(\frac{1}{0.5} + \frac{1}{0.8} - 1\right) + \left(\frac{1}{0.15} + \frac{1}{0.15} - 1\right)}$$

$$= \mathbf{1857\ W/m^2}$$

The net rate of radiation heat transfer between the plates in the case of no shield is

$$\dot{Q}_{12,no\ \text{shield}} = \frac{\sigma(T_1^4 - T_2^4)}{\left(\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1\right)} = \frac{(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(900\ \text{K})^4 - (650\ \text{K})^4]}{\left(\frac{1}{0.5} + \frac{1}{0.8} - 1\right)} = 12{,}035\ \text{W/m}^2$$

Then the ratio of radiation heat transfer for the two cases becomes

$$\frac{\dot{Q}_{12,\text{one shield}}}{\dot{Q}_{12,\text{no shield}}} = \frac{1857\ \text{W}}{12{,}035\ \text{W}} \cong \mathbf{\frac{1}{6}}$$

12-53 Two very large plates are maintained at uniform temperatures. The number of thin aluminum sheets that will reduce the net rate of radiation heat transfer between the two plates to one-fifth is to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

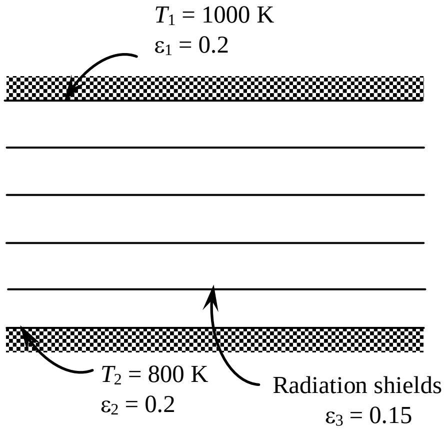
Properties The emissivities of surfaces are given to be $\varepsilon_1 = 0.2$, $\varepsilon_2 = 0.2$, and $\varepsilon_3 = 0.15$.

Analysis The net rate of radiation heat transfer between the plates in the case of no shield is

$$\dot{Q}_{12,no\,\text{shield}} = \frac{\sigma(T_1^{\,4} - T_2^{\,4})}{\left(\dfrac{1}{\varepsilon_1} + \dfrac{1}{\varepsilon_2} - 1\right)}$$

$$= \frac{(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(1000\ \text{K})^4 - (800\ \text{K})^4]}{\left(\dfrac{1}{0.2} + \dfrac{1}{0.2} - 1\right)}$$

$$= 3720\ \text{W/m}^2$$



The number of sheets that need to be inserted in order to reduce the net rate of heat transfer between the two plates to onefifth can be determined from

$$\dot{Q}_{12,\text{shields}} = \frac{\sigma(T_1^{\,4} - T_2^{\,4})}{\left(\dfrac{1}{\varepsilon_1} + \dfrac{1}{\varepsilon_2} - 1\right) + N_\text{shield}\left(\dfrac{1}{\varepsilon_{3,1}} + \dfrac{1}{\varepsilon_{3,2}} - 1\right)}$$

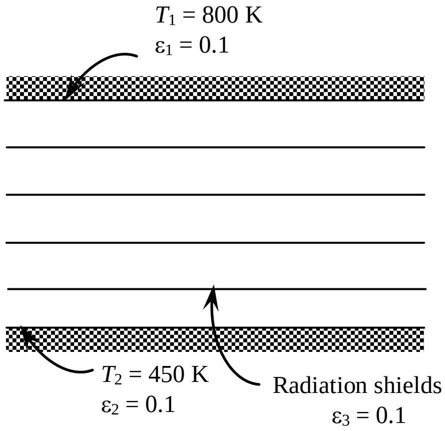
$$\frac{1}{5}(3720\ \text{W/m}^2) = \frac{(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(1000\ \text{K})^4 - (800\ \text{K})^4]}{\left(\dfrac{1}{0.2} + \dfrac{1}{0.2} - 1\right) + N_\text{shield}\left(\dfrac{1}{0.15} + \dfrac{1}{0.15} - 1\right)} \longrightarrow N_\text{shield} = 2.92 \cong \mathbf{3}$$

12-54 Five identical thin aluminum sheets are placed between two very large parallel plates which are maintained at uniform temperatures. The net rate of radiation heat transfer between the two plates is to be determined and compared with that without the shield.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivities of surfaces are given to be $\varepsilon_1 = \varepsilon_2 = 0.1$ and $\varepsilon_3 = 0.1$.

Analysis Since the plates and the sheets have the same emissivity value, the net rate of radiation heat transfer with 5 thin aluminum shield can be determined from



$$\dot{Q}_{12,5\,\text{shield}} = \frac{1}{N+1}\dot{Q}_{12,\,\text{no shield}} = \frac{1}{N+1}\frac{\sigma(T_1^{\,4} - T_2^{\,4})}{\left(\dfrac{1}{\varepsilon_1} + \dfrac{1}{\varepsilon_2} - 1\right)}$$

$$= \frac{1}{5+1}\frac{(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(800\ \text{K})^4 - (450\ \text{K})^4]}{\left(\dfrac{1}{0.1} + \dfrac{1}{0.1} - 1\right)}$$

$$= \mathbf{183\ W/m^2}$$

The net rate of radiation heat transfer without the shield is

$$\dot{Q}_{12,5\,\text{shield}} = \frac{1}{N+1}\dot{Q}_{12,\,\text{no shield}} \longrightarrow \dot{Q}_{12,\,\text{no shield}} = (N+1)\dot{Q}_{12,5\,\text{shield}} = 6\times183\ \text{W} = \mathbf{1098\ W}$$

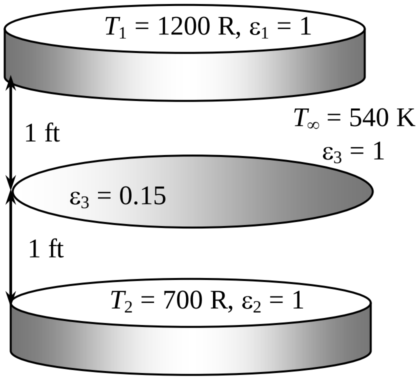
12-56E A radiation shield is placed between two parallel disks which are maintained at uniform temperatures. The net rate of radiation heat transfer through the shields is to be determined.



T_1 = 1200 R, ε_1 = 1
1 ft
T_∞ = 540 K
ε_3 = 1
ε_3 = 0.15
1 ft
T_2 = 700 R, ε_2 = 1

Assumptions **1** Steady operating conditions exist **2** The surfaces are black. **3** Convection heat transfer is not considered.

Properties The emissivities of surfaces are given to be $\varepsilon_1 = \varepsilon_2 = 1$ and $\varepsilon_3 = 0.15$.

Analysis From Fig. 12-44 we have $F_{32} = F_{13} = 0.52$. Then $F_{34} = 1 - 0.52 = 0.48$. The disk in the middle is surrounded by black surfaces on both sides. Therefore, heat transfer between the top surface of the middle disk and its black surroundings can expressed as

$$\begin{aligned}\dot{Q}_3 &= \varepsilon A_3\sigma[F_{31}(T_3^4 - T_1^4)] + \varepsilon A_3\sigma[F_{32}(T_3^4 - T_2^4)]\\ &= 0.15(7.069\text{ ft}^2)(0.1714\times10^{-8}\text{ Btu/h.ft}^2\cdot\text{R}^4)\{0.52[(T_3^4 - (1200\text{ R})^4] + 0.48[T_3^4 - (540\text{ K})^4]\}\end{aligned}$$

Similarly, for the bottom surface of the middle disk, we have

$$\begin{aligned}-\dot{Q}_3 &= \varepsilon A_3\sigma[F_{34}(T_3^4 - T_4^4)] + \varepsilon A_3\sigma[F_{35}(T_3^4 - T_5^4)]\\ &= 0.15(7.069\text{ ft}^2)(0.1714\times10^{-8}\text{ Btu/h.ft}^2\cdot\text{R}^4)\{0.48[(T_3^4 - (700\text{ R})^4] + 0.52[T_3^4 - (540\text{ K})^4]\}\end{aligned}$$

Combining the equations above, the rate of heat transfer between the disks through the radiation shield (the middle disk) is determined to be

$\dot{Q}$ = **866 Btu/h** and T_3 = 895 K

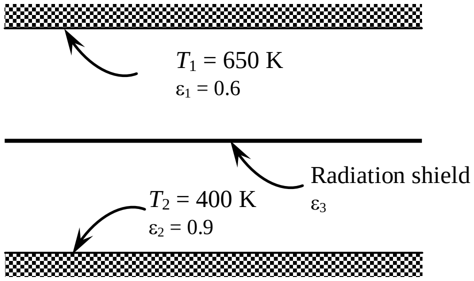
12-57 A radiation shield is placed between two large parallel plates which are maintained at uniform temperatures. The emissivity of the radiation shield is to be determined if the radiation heat transfer between the plates is reduced to 15% of that without the radiation shield.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivities of surfaces are given to be $\varepsilon_1 = 0.6$ and $\varepsilon_2 = 0.9$.

Analysis First, the net rate of radiation heat transfer between the two large parallel plates per unit area without a shield is

$$\dot{Q}_{12,\text{no shield}} = \frac{\sigma(T_1^{\,4} - T_2^{\,4})}{\dfrac{1}{\varepsilon_1} + \dfrac{1}{\varepsilon_2} - 1} = \frac{(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(650\ \text{K})^4 - (400\ \text{K})^4]}{\dfrac{1}{0.6} + \dfrac{1}{0.9} - 1} = 4877\ \text{W/m}^2$$



The radiation heat transfer in the case of one shield is

$$\begin{aligned}\dot{Q}_{12,\text{one shield}} &= 0.15\times\dot{Q}_{12,\text{no shield}}\\ &= 0.15\times4877\ \text{W/m}^2 = 731.6\ \text{W/m}^2\end{aligned}$$

Then the emissivity of the radiation shield becomes

$$\dot{Q}_{12,\text{one shield}} = \frac{\sigma(T_1^{\,4} - T_2^{\,4})}{\left(\dfrac{1}{\varepsilon_1} + \dfrac{1}{\varepsilon_2} - 1\right) + \left(\dfrac{1}{\varepsilon_{3,1}} + \dfrac{1}{\varepsilon_{3,2}} - 1\right)}$$

$$731.6\ \text{W/m}^2 = \frac{(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(650\ \text{K})^4 - (400\ \text{K})^4]}{\left(\dfrac{1}{0.6} + \dfrac{1}{0.9} - 1\right) + \left(\dfrac{2}{\varepsilon_3} - 1\right)}$$

which gives $\varepsilon_3 = \mathbf{0.18}$

12-59 A coaxial radiation shield is placed between two coaxial cylinders which are maintained at uniform temperatures. The net rate of radiation heat transfer between the two cylinders is to be determined and compared with that without the shield.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivities of surfaces are given to be ε₁ = 0.7, ε₂ = 0.4. and ε₃ = 0.2.

Analysis The surface areas of the cylinders and the shield per unit length are

$$A_{\text{pipe,inner}} = A_1 = \pi D_1 L = \pi(0.2\text{ m})(1\text{ m}) = 0.628\text{ m}^2$$
$$A_{\text{pipe,outer}} = A_2 = \pi D_2 L = \pi(0.1\text{ m})(1\text{ m}) = 0.314\text{ m}^2$$
$$A_{\text{shield}} = A_3 = \pi D_3 L = \pi(0.3\text{ m})(1\text{ m}) = 0.942\text{ m}^2$$

The net rate of radiation heat transfer between the two cylinders with a shield per unit length is

$$\begin{aligned}\dot{Q}_{12,\text{one shield}} &= \frac{\sigma(T_1^{\,4}-T_2^{\,4})}{\dfrac{1-\varepsilon_1}{A_1\varepsilon_1}+\dfrac{1}{A_1F_{13}}+\dfrac{1-\varepsilon_{3,1}}{A_3\varepsilon_{3,1}}+\dfrac{1-\varepsilon_{3,2}}{A_3\varepsilon_{3,2}}+\dfrac{1}{A_3F_{3,2}}+\dfrac{1-\varepsilon_2}{A_2\varepsilon_2}}\\ &= \frac{(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[(750\text{ K})^4-(500\text{ K})^4]}{\dfrac{1-0.7}{(0.314)(0.7)}+\dfrac{1}{(0.314)(1)}+2\dfrac{1-0.2}{(0.628)(0.2)}+\dfrac{1}{(0.628)(1)}+\dfrac{1-0.4}{(0.942)(0.4)}}\\ &= \mathbf{703\ W}\end{aligned}$$

If there was no shield,

$$\begin{aligned}\dot{Q}_{12,\text{no shield}} &= \frac{\sigma(T_1^{\,4}-T_2^{\,4})}{\dfrac{1}{\varepsilon_1}+\dfrac{1-\varepsilon_2}{\varepsilon_2}\left(\dfrac{D_1}{D_2}\right)}\\ &= \frac{(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[(750\text{ K})^4-(500\text{ K})^4]}{\dfrac{1}{0.7}+\dfrac{1-0.4}{0.4}\left(\dfrac{0.1}{0.3}\right)}\\ &= \mathbf{7465\ W}\end{aligned}$$

Then their ratio becomes

$$\frac{\dot{Q}_{12,\text{one shield}}}{\dot{Q}_{12,\text{no shield}}} = \frac{703\text{ W}}{7465\text{ W}} = \mathbf{0.094}$$

Radiation Exchange with Absorbing and Emitting Gases

12-61C A nonparticipating medium is completely transparent to thermal radiation, and thus it does not emit, absorb, or scatter radiation. A participating medium, on the other hand, emits and absorbs radiation throughout its entire volume.

12-62C Spectral transmissivity of a medium of thickness L is the ratio of the intensity of radiation leaving the medium to that entering the medium, and is expressed as $\tau_\lambda = \dfrac{I_{\lambda,L}}{I_{\lambda,0}} = e^{-\kappa_\lambda L}$ and $\tau_\lambda = 1 - \alpha_\lambda$.

12-63C Using Kirchhoff's law, the spectral emissivity of a medium of thickness L in terms of the spectral absorption coefficient is expressed as $\varepsilon_\lambda = \alpha_\lambda = 1 - e^{-\kappa_\lambda L}$.

12-64C Gases emit and absorb radiation at a number of narrow wavelength bands. The emissivity-wavelength charts of gases typically involve various peaks and dips together with discontinuities, and show clearly the band nature of absorption and the strong nongray characteristics. This is in contrast to solids, which emit and absorb radiation over the entire spectrum.

12-65 An equimolar mixture of CO_2 and O_2 gases at 500 K and a total pressure of 0.5 atm is considered. The emissivity of the gas is to be determined.

Assumptions All the gases in the mixture are ideal gases.

Analysis Volumetric fractions are equal to pressure fractions. Therefore, the partial pressure of CO_2 is

$$P_c = y_{CO_2} P = 0.5(0.5\,\text{atm}) = 0.25\,\text{atm}$$

Then,

$$P_c L = (0.25\,\text{atm})(1.2\,\text{m}) = 0.30\,\text{m}\cdot\text{atm} = 0.98\,\text{ft}\cdot\text{atm}$$

The emissivity of CO_2 corresponding to this value at the gas temperature of T_g = 500 K and 1 atm is, from Fig. 12-36,

$$\varepsilon_{c,1\,\text{atm}} = 0.14$$

This is the base emissivity value at 1 atm, and it needs to be corrected for the 0.5 atm total pressure. The pressure correction factor is, from Fig. 12-37,

$$C_c = 0.90$$

Then the effective emissivity of the gas becomes

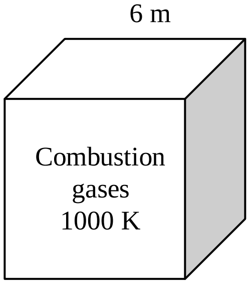
$$\varepsilon_g = C_c \varepsilon_{c,1\,\text{atm}} = 0.90 \times 0.14 = \mathbf{0.126}$$

12-66 The temperature, pressure, and composition of a gas mixture is given. The emissivity of the mixture is to be determined.

Assumptions **1** All the gases in the mixture are ideal gases. **2** The emissivity determined is the mean emissivity for radiation emitted to all surfaces of the cubical enclosure.

Analysis The volumetric analysis of a gas mixture gives the mole fractions y_i of the components, which are equivalent to pressure fractions for an ideal gas mixture. Therefore, the partial pressures of CO_2 and H_2O are

$$P_c = y_{CO_2} P = 0.10(1\,\text{atm}) = 0.10\,\text{atm}$$
$$P_w = y_{H_2O} P = 0.09(1\,\text{atm}) = 0.09\,\text{atm}$$



The mean beam length for a cube of side length 6 m for radiation emitted to all surfaces is, from Table 12-4,

$$L = 0.66(6\text{ m}) = 3.96\text{ m}$$

Then,

$$P_c L = (0.10\,\text{atm})(3.96\,\text{m}) = 0.396\,\text{m}\cdot\text{atm} = 1.30\,\text{ft}\cdot\text{atm}$$
$$P_w L = (0.09\,\text{atm})(3.96\,\text{m}) = 0.48\,\text{m}\cdot\text{atm} = 1.57\,\text{ft}\cdot\text{atm}$$

The emissivities of CO_2 and H_2O corresponding to these values at the gas temperature of T_g = 1000 K and 1atm are, from Fig. 12-36,

$$\varepsilon_{c,1\,\text{atm}} = 0.17 \quad \text{and} \quad \varepsilon_{w,1\,\text{atm}} = 0.26$$

Both CO_2 and H_2O are present in the same mixture, and we need to correct for the overlap of emission bands. The emissivity correction factor at $T = T_g$ = 1000 K is, from Fig. 12-38,

$$\left.\begin{array}{l} P_c L + P_w L = 1.30 + 1.57 = 2.87 \\ \dfrac{P_w}{P_w + P_c} = \dfrac{0.09}{0.09 + 0.10} = 0.474 \end{array}\right\} \Delta\varepsilon = 0.039$$

Note that we obtained the average of the emissivity correction factors from the two figures for 800 K and 1200 K. Then the effective emissivity of the combustion gases becomes

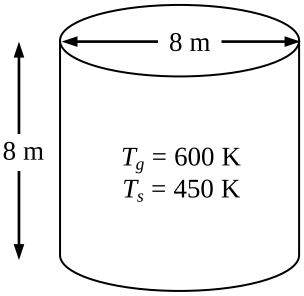
$$\varepsilon_g = C_c \varepsilon_{c,1\,\text{atm}} + C_w \varepsilon_{w,1\,\text{atm}} - \Delta\varepsilon = 1\times 0.17 + 1\times 0.26 - 0.039 = \mathbf{0.391}$$

Note that the pressure correction factor is 1 for both gases since the total pressure is 1 atm.

12-67 A mixture of CO_2 and N_2 gases at 600 K and a total pressure of 1 atm are contained in a cylindrical container. The rate of radiation heat transfer between the gas and the container walls is to be determined.

Assumptions All the gases in the mixture are ideal gases.

Analysis The mean beam length is, from Table 12-4



$$L = 0.60D = 0.60(8\text{ m}) = 4.8\text{ m}$$

Then,

$$P_c L = (0.15\text{ atm})(4.8\text{ m}) = 0.72\text{ m}\cdot\text{atm} = 2.36\text{ ft}\cdot\text{atm}$$

The emissivity of CO_2 corresponding to this value at the gas temperature of T_g = 600 K and 1 atm is, from Fig. 12-36,

$$\varepsilon_{c,1\,\text{atm}} = 0.24$$

For a source temperature of T_s = 450 K, the absorptivity of the gas is again determined using the emissivity charts as follows:

$$P_c L\frac{T_s}{T_g} = (0.15\text{ atm})(4.8\text{ m})\frac{450\text{ K}}{600\text{ K}} = 0.54\text{ m}\cdot\text{atm} = 1.77\text{ ft}\cdot\text{atm}$$

The emissivity of CO_2 corresponding to this value at a temperature of T_s = 450 K and 1atm are, from Fig. 12-36,

$$\varepsilon_{c,1\,\text{atm}} = 0.14$$

The absorptivity of CO_2 is determined from

$$\alpha_c = C_c\left(\frac{T_g}{T_s}\right)^{0.65}\varepsilon_{c,1\,\text{atm}} = (1)\left(\frac{600\text{ K}}{450\text{ K}}\right)^{0.65}(0.14) = 0.17$$

The surface area of the cylindrical surface is

$$A_s = \pi DH + 2\frac{\pi D^2}{4} = \pi(8\text{ m})(8\text{ m}) + 2\frac{\pi(8\text{ m})^2}{4} = 301.6\text{ m}^2$$

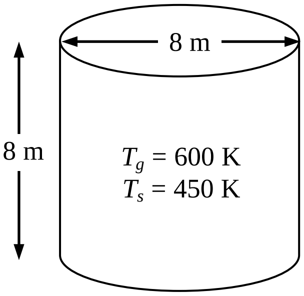
Then the net rate of radiation heat transfer from the gas mixture to the walls of the furnace becomes

$$\begin{aligned}\dot{Q}_{\text{net}} &= A_s\sigma(\varepsilon_g T_g^4 - \alpha_g T_s^4)\\ &= (301.6\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[0.14(600\text{ K})^4 - 0.17(450\text{ K})^4]\\ &= \mathbf{1.91\times10^5\ W}\end{aligned}$$

12-68 A mixture of H_2O and N_2 gases at 600 K and a total pressure of 1 atm are contained in a cylindrical container. The rate of radiation heat transfer between the gas and the container walls is to be determined.

Assumptions All the gases in the mixture are ideal gases.

Analysis The mean beam length is, from Table 12-4



$$L = 0.60D = 0.60(8\text{ m}) = 4.8\text{ m}$$

Then,

$$P_w L = (0.15\text{ atm})(4.8\text{ m}) = 0.72\text{ m}\cdot\text{atm} = 2.36\text{ ft}\cdot\text{atm}$$

The emissivity of H_2O corresponding to this value at the gas temperature of T_g = 600 K and 1 atm is, from Fig. 12-36,

$$\varepsilon_{w1\text{atm}} = 0.36$$

For a source temperature of T_s = 450 K, the absorptivity of the gas is again determined using the emissivity charts as follows:

$$P_w L\frac{T_s}{T_g} = (0.15\text{ atm})(4.8\text{ m})\frac{450\text{ K}}{600\text{ K}} = 0.54\text{ m}\cdot\text{atm} = 1.77\text{ ft}\cdot\text{atm}$$

The emissivity of H_2O corresponding to this value at a temperature of T_s = 450 K and 1atm are, from Fig. 12-36,

$$\varepsilon_{w,1\text{atm}} = 0.34$$

The absorptivity of H_2O is determined from

$$\alpha_w = C_w\left(\frac{T_g}{T_s}\right)^{0.65}\varepsilon_{w,1\text{atm}} = (1)\left(\frac{600\text{ K}}{450\text{ K}}\right)^{0.45}(0.34) = 0.39$$

The surface area of the cylindrical surface is

$$A_s = \pi DH + 2\frac{\pi D^2}{4} = \pi(8\text{ m})(8\text{ m}) + 2\frac{\pi(8\text{ m})^2}{4} = 301.6\text{ m}^2$$

Then the net rate of radiation heat transfer from the gas mixture to the walls of the furnace becomes

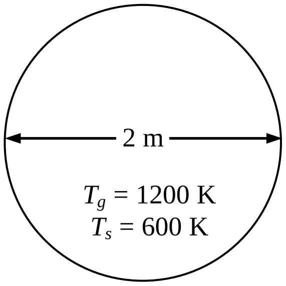
$$\begin{aligned}\dot{Q}_{\text{net}} &= A_s\sigma(\varepsilon_g T_g^4 - \alpha_g T_s^4)\\ &= (301.6\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[0.36(600\text{ K})^4 - 0.39(450\text{ K})^4]\\ &= \mathbf{5.244\times10^5\ W}\end{aligned}$$

12-69 A mixture of CO_2 and N_2 gases at 1200 K and a total pressure of 1 atm are contained in a spherical furnace. The net rate of radiation heat transfer between the gas mixture and furnace walls is to be determined.

Assumptions All the gases in the mixture are ideal gases.

Analysis The mean beam length is, from Table 12-4

$$L = 0.65D = 0.65(2\text{ m}) = 1.3\text{ m}$$



The mole fraction is equal to pressure fraction. Then,

$$P_c L = (0.15\text{ atm})(1.3\text{ m}) = 0.195\text{ m}\cdot\text{atm} = 0.64\text{ ft}\cdot\text{atm}$$

The emissivity of CO_2 corresponding to this value at the gas temperature of T_g = 1200 K and 1 atm is, from Fig. 12-36,

$$\varepsilon_{c,1\,\text{atm}} = 0.14$$

For a source temperature of T_s = 600 K, the absorptivity of the gas is again determined using the emissivity charts as follows:

$$P_c L\frac{T_s}{T_g} = (0.15\text{ atm})(1.3\text{ m})\frac{600\text{ K}}{1200\text{ K}} = 0.0975\text{ m}\cdot\text{atm} = 0.32\text{ ft}\cdot\text{atm}$$

The emissivity of CO_2 corresponding to this value at a temperature of T_s = 600 K and 1atm are, from Fig. 12-36,

$$\varepsilon_{c,1\,\text{atm}} = 0.092$$

The absorptivity of CO_2 is determined from

$$\alpha_c = C_c\left(\frac{T_g}{T_s}\right)^{0.65}\varepsilon_{c,1\,\text{atm}} = (1)\left(\frac{1200\text{ K}}{600\text{ K}}\right)^{0.65}(0.092) = 0.144$$

The surface area of the sphere is

$$A_s = \pi D^2 = \pi(2\text{ m})^2 = 12.57\text{ m}^2$$

Then the net rate of radiation heat transfer from the gas mixture to the walls of the furnace becomes

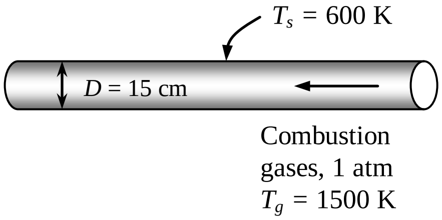
$$\begin{aligned}\dot{Q}_{\text{net}} &= A_s\sigma(\varepsilon_g T_g^4 - \alpha_g T_s^4)\\ &= (12.57\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[0.14(1200\text{ K})^4 - 0.144(600\text{ K})^4]\\ &= \mathbf{1.936\times10^5\text{ W}}\end{aligned}$$

12-70 The temperature, pressure, and composition of combustion gases flowing inside long tubes are given. The rate of heat transfer from combustion gases to tube wall is to be determined.

Assumptions All the gases in the mixture are ideal gases.

Analysis The volumetric analysis of a gas mixture gives the mole fractions y_i of the components, which are equivalent to pressure fractions for an ideal gas mixture. Therefore, the partial pressures of CO_2 and H_2O are

$$P_c = y_{CO_2} P = 0.06(1\,\text{atm}) = 0.06\,\text{atm}$$
$$P_w = y_{H_2O} P = 0.09(1\,\text{atm}) = 0.09\,\text{atm}$$



The mean beam length for an infinite cicrcular cylinder is, from Table 12-4,

$$L = 0.95(0.15\text{ m}) = 0.1425\text{ m}$$

Then,

$$P_c L = (0.06\,\text{atm})(0.1425\,\text{m}) = 0.00855\,\text{m}\cdot\text{atm} = 0.028\,\text{ft}\cdot\text{atm}$$
$$P_w L = (0.09\,\text{atm})(0.1425\,\text{m}) = 0.0128\,\text{m}\cdot\text{atm} = 0.042\,\text{ft}\cdot\text{atm}$$

The emissivities of CO_2 and H_2O corresponding to these values at the gas temperature of T_g = 1500 K and 1atm are, from Fig. 12-36,

$$\varepsilon_{c,1\,\text{atm}} = 0.034 \quad \text{and} \quad \varepsilon_{w,1\,\text{atm}} = 0.016$$

Both CO_2 and H_2O are present in the same mixture, and we need to correct for the overlap of emission bands. The emissivity correction factor at $T = T_g$ = 1500 K is, from Fig. 12-38,

$$\left.\begin{array}{l} P_c L + P_w L = 0.028 + 0.042 = 0.07 \\ \dfrac{P_w}{P_w + P_c} = \dfrac{0.09}{0.09 + 0.06} = 0.6 \end{array}\right\} \Delta\varepsilon = 0.0$$

Then the effective emissivity of the combustion gases becomes

$$\varepsilon_g = C_c \varepsilon_{c,1\,\text{atm}} + C_w \varepsilon_{w,1\,\text{atm}} - \Delta\varepsilon = 1\times 0.034 + 1\times 0.016 - 0.0 = 0.05$$

Note that the pressure correction factor is 1 for both gases since the total pressure is 1 atm. For a source temperature of T_s = 600 K, the absorptivity of the gas is again determined using the emissivity charts as follows:

$$P_c L \frac{T_s}{T_g} = (0.06\,\text{atm})(0.1425\,\text{m})\frac{600\,\text{K}}{1500\,\text{K}} = 0.00342\,\text{m}\cdot\text{atm} = 0.011\,\text{ft}\cdot\text{atm}$$
$$P_w L \frac{T_s}{T_g} = (0.09\,\text{atm})(0.1425\,\text{m})\frac{600\,\text{K}}{1500\,\text{K}} = 0.00513\,\text{m}\cdot\text{atm} = 0.017\,\text{ft}\cdot\text{atm}$$

The emissivities of CO_2 and H_2O corresponding to these values at a temperature of T_s = 600 K and 1atm are, from Fig. 12-36,

$$\varepsilon_{c,1\,\text{atm}} = 0.031 \quad \text{and} \quad \varepsilon_{w,1\,\text{atm}} = 0.027$$

Then the absorptivities of CO_2 and H_2O become

$$\alpha_c = C_c \left(\frac{T_g}{T_s}\right)^{0.65} \varepsilon_{c,1\,\text{atm}} = (1)\left(\frac{1500\,\text{K}}{600\,\text{K}}\right)^{0.65} (0.031) = 0.056$$
$$\alpha_w = C_w \left(\frac{T_g}{T_s}\right)^{0.45} \varepsilon_{w,1\,\text{atm}} = (1)\left(\frac{1500\,\text{K}}{600\,\text{K}}\right)^{0.45} (0.027) = 0.041$$

Also $\Delta\alpha = \Delta\varepsilon$, but the emissivity correction factor is to be evaluated from Fig. 12-38 at $T = T_s = 600$ K instead of $T_g = 1500$ K. There is no chart for 600 K in the figure, but we can read $\Delta\varepsilon$ values at 400 K and 800 K, and take their average. At $P_w/(P_w + P_c) = 0.6$ and $P_cL + P_wL = 0.07$ we read $\Delta\varepsilon = 0.0$. Then the absorptivity of the combustion gases becomes

$$\alpha_g = \alpha_c + \alpha_w - \Delta\alpha = 0.056 + 0.041 - 0.0 = 0.097$$

The surface area of the pipe per m length of tube is

$$A_s = \pi DL = \pi(0.15\text{ m})(1\text{ m}) = 0.4712\text{ m}^2$$

Then the net rate of radiation heat transfer from the combustion gases to the walls of the furnace becomes

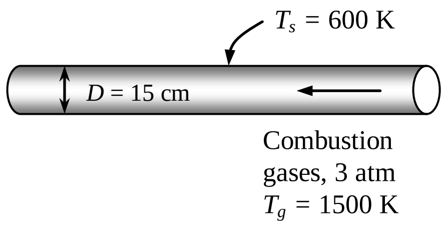
$$\begin{aligned}\dot{Q}_{\text{net}} &= A_s\sigma(\varepsilon_g T_g^4 - \alpha_g T_s^4)\\ &= (0.4712\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[0.05(1500\text{ K})^4 - 0.097(600\text{ K})^4]\\ &= \mathbf{6427\ W}\end{aligned}$$

12-71 The temperature, pressure, and composition of combustion gases flowing inside long tubes are given. The rate of heat transfer from combustion gases to tube wall is to be determined.

Assumptions All the gases in the mixture are ideal gases.

Analysis The volumetric analysis of a gas mixture gives the mole fractions y_i of the components, which are equivalent to pressure fractions for an ideal gas mixture. Therefore, the partial pressures of CO_2 and H_2O are

$$P_c = y_{\mathrm{CO_2}} P = 0.06(1\,\mathrm{atm}) = 0.06\,\mathrm{atm}$$
$$P_w = y_{\mathrm{H_2O}} P = 0.09(1\,\mathrm{atm}) = 0.09\,\mathrm{atm}$$



The mean beam length for an infinite cicrcular cylinder is, from Table 12-4,

$$L = 0.95(0.15\text{ m}) = 0.1425\text{ m}$$

Then,

$$P_c L = (0.06\,\mathrm{atm})(0.1425\,\mathrm{m}) = 0.00855\,\mathrm{m\cdot atm} = 0.028\,\mathrm{ft\cdot atm}$$
$$P_w L = (0.09\,\mathrm{atm})(0.1425\,\mathrm{m}) = 0.0128\,\mathrm{m\cdot atm} = 0.042\,\mathrm{ft\cdot atm}$$

The emissivities of CO_2 and H_2O corresponding to these values at the gas temperature of T_g = 1500 K and 1atm are, from Fig. 12-36,

$$\varepsilon_{c,1\,\mathrm{atm}} = 0.034 \quad \text{and} \quad \varepsilon_{w,1\,\mathrm{atm}} = 0.016$$

These are base emissivity values at 1 atm, and they need to be corrected for the 3 atm total pressure. Noting that $(P_w+P)/2 = (0.09+3)/2 = 1.545$ atm, the pressure correction factors are, from Fig. 12-37,

$$C_c = 1.5 \quad \text{and} \quad C_w = 1.8$$

Both CO_2 and H_2O are present in the same mixture, and we need to correct for the overlap of emission bands. The emissivity correction factor at $T = T_g$ = 1500 K is, from Fig. 12-38,

$$\left.\begin{aligned} &P_c L + P_w L = 0.028 + 0.042 = 0.07 \\ &\frac{P_w}{P_w + P_c} = \frac{0.09}{0.09 + 0.06} = 0.6 \end{aligned}\right\} \Delta\varepsilon = 0.0$$

Then the effective emissivity of the combustion gases becomes

$$\varepsilon_g = C_c \varepsilon_{c,1\,\mathrm{atm}} + C_w \varepsilon_{w,1\,\mathrm{atm}} - \Delta\varepsilon = 1.5\times 0.034 + 1.8\times 0.016 - 0.0 = 0.080$$

For a source temperature of T_s = 600 K, the absorptivity of the gas is again determined using the emissivity charts as follows:

$$P_c L\frac{T_s}{T_g} = (0.06\,\mathrm{atm})(0.1425\,\mathrm{m})\frac{600\,\mathrm{K}}{1500\,\mathrm{K}} = 0.00342\,\mathrm{m\cdot atm} = 0.011\,\mathrm{ft\cdot atm}$$
$$P_w L\frac{T_s}{T_g} = (0.09\,\mathrm{atm})(0.1425\,\mathrm{m})\frac{600\,\mathrm{K}}{1500\,\mathrm{K}} = 0.00513\,\mathrm{m\cdot atm} = 0.017\,\mathrm{ft\cdot atm}$$

The emissivities of CO_2 and H_2O corresponding to these values at a temperature of T_s = 600 K and 1atm are, from Fig. 12-36,

$$\varepsilon_{c,1\,\mathrm{atm}} = 0.031 \quad \text{and} \quad \varepsilon_{w,1\,\mathrm{atm}} = 0.027$$

Then the absorptivities of CO_2 and H_2O become

$$\alpha_c = C_c \left(\frac{T_g}{T_s}\right)^{0.65} \varepsilon_{c,1\,\text{atm}} = (1.5)\left(\frac{1500\text{ K}}{600\text{ K}}\right)^{0.65} (0.031) = 0.084$$

$$\alpha_w = C_w \left(\frac{T_g}{T_s}\right)^{0.45} \varepsilon_{w,1\,\text{atm}} = (1.8)\left(\frac{1500\text{ K}}{600\text{ K}}\right)^{0.45} (0.027) = 0.073$$

Also $\Delta\alpha = \Delta\varepsilon$, but the emissivity correction factor is to be evaluated from Fig. 12-38 at $T = T_s = 600$ K instead of $T_g = 1500$ K. There is no chart for 600 K in the figure, but we can read $\Delta\varepsilon$ values at 400 K and 800 K, and take their average. At $P_w/(P_w + P_c) = 0.6$ and $P_cL + P_wL = 0.07$ we read $\Delta\varepsilon = 0.0$. Then the absorptivity of the combustion gases becomes

$$\alpha_g = \alpha_c + \alpha_w - \Delta\alpha = 0.084 + 0.073 - 0.0 = 0.157$$

The surface area of the pipe per m length of tube is

$$A_s = \pi DL = \pi(0.15\text{ m})(1\text{ m}) = 0.4712\text{ m}^2$$

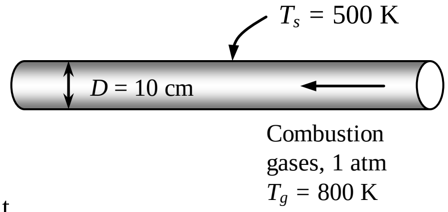
Then the net rate of radiation heat transfer from the combustion gases to the walls of the furnace becomes

$$\begin{aligned}\dot{Q}_{\text{net}} &= A_s\sigma(\varepsilon_g T_g^4 - \alpha_g T_s^4)\\ &= (0.4712\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[0.08(1500\text{ K})^4 - 0.157(600\text{ K})^4]\\ &= \mathbf{10{,}276\ W}\end{aligned}$$

12-72 The temperature, pressure, and composition of combustion gases flowing inside long tubes are given. The rate of heat transfer from combustion gases to tube wall is to be determined.

Assumptions All the gases in the mixture are ideal gases.

Analysis The mean beam length for an infinite cicrcular cylinder is, from Table 12-4,



$$L = 0.95(0.10\text{ m}) = 0.095\text{ m}$$

Then,

$$P_c L = (0.12\text{ atm})(0.095\text{ m}) = 0.0114\text{ m}\cdot\text{atm} = 0.037\text{ ft}\cdot\text{atm}$$
$$P_w L = (0.18\text{ atm})(0.095\text{ m}) = 0.0171\text{ m}\cdot\text{atm} = 0.056\text{ ft}\cdot\text{atm}$$

The emissivities of CO_2 and H_2O corresponding to these values at the gas temperature of T_g = 800 K and 1atm are, from Fig. 12-36,

$$\varepsilon_{c,1\text{ atm}} = 0.055 \quad\text{and}\quad \varepsilon_{w,1\text{ atm}} = 0.050$$

Both CO_2 and H_2O are present in the same mixture, and we need to correct for the overlap of emission bands. The emissivity correction factor at $T = T_g$ = 800 K is, from Fig. 12-38,

$$\left.\begin{array}{l} P_c L + P_w L = 0.037 + 0.056 = 0.093 \\ \dfrac{P_w}{P_w + P_c} = \dfrac{0.18}{0.18+0.12} = 0.6 \end{array}\right\} \Delta\varepsilon = 0.0$$

Then the effective emissivity of the combustion gases becomes

$$\varepsilon_g = C_c \varepsilon_{c,1\text{ atm}} + C_w \varepsilon_{w,1\text{ atm}} - \Delta\varepsilon = 1\times 0.055 + 1\times 0.050 - 0.0 = 0.105$$

Note that the pressure correction factor is 1 for both gases since the total pressure is 1 atm. For a source temperature of T_s = 500 K, the absorptivity of the gas is again determined using the emissivity charts as follows:

$$P_c L \frac{T_s}{T_g} = (0.12\text{ atm})(0.095\text{ m})\frac{500\text{ K}}{800\text{ K}} = 0.007125\text{ m}\cdot\text{atm} = 0.023\text{ ft}\cdot\text{atm}$$
$$P_w L \frac{T_s}{T_g} = (0.18\text{ atm})(0.095\text{ m})\frac{500\text{ K}}{800\text{ K}} = 0.01069\text{ m}\cdot\text{atm} = 0.035\text{ ft}\cdot\text{atm}$$

The emissivities of CO_2 and H_2O corresponding to these values at a temperature of T_s = 500 K and 1atm are, from Fig. 12-36,

$$\varepsilon_{c,1\text{ atm}} = 0.042 \quad\text{and}\quad \varepsilon_{w,1\text{ atm}} = 0.050$$

Then the absorptivities of CO_2 and H_2O become

$$\alpha_c = C_c \left(\frac{T_g}{T_s}\right)^{0.65} \varepsilon_{c,1\text{ atm}} = (1)\left(\frac{800\text{ K}}{500\text{ K}}\right)^{0.65}(0.042) = 0.057$$
$$\alpha_w = C_w \left(\frac{T_g}{T_s}\right)^{0.45} \varepsilon_{w,1\text{ atm}} = (1)\left(\frac{800\text{ K}}{500\text{ K}}\right)^{0.45}(0.050) = 0.062$$

Also $\Delta\alpha = \Delta\varepsilon$, but the emissivity correction factor is to be evaluated from Fig. 12-38 at $T = T_s$ = 500 K instead of T_g = 800 K. There is no chart for 500 K in the figure, but we can read $\Delta\varepsilon$ values at 400 K and 800 K, and interpolate. At $P_w/(P_w + P_c)$ = 0.6 and $P_cL + P_wL$ = 0.093 we read $\Delta\varepsilon$ = 0.0. Then the absorptivity of the combustion gases becomes

$$\alpha_g = \alpha_c + \alpha_w - \Delta\alpha = 0.057 + 0.062 - 0.0 = 0.119$$

The surface area of the pipe is

$$A_s = \pi D L = \pi(0.10\text{ m})(6\text{ m}) = 1.885\text{ m}^2$$

Then the net rate of radiation heat transfer from the combustion gases to the walls of the tube becomes

$$\begin{aligned}\dot{Q}_\text{net} &= A_s\sigma(\varepsilon_g T_g^4 - \alpha_g T_s^4)\\ &= (1.885\text{ m}^2)(5.67\times 10^{-8}\text{ W/m}^2\cdot\text{K}^4)[0.105(800\text{ K})^4 - 0.119(500\text{ K})^4]\\ &= \mathbf{3802\ W}\end{aligned}$$

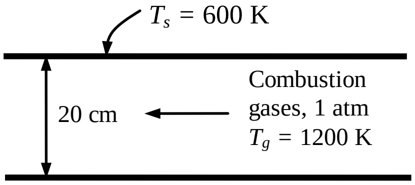
12-73 The temperature, pressure, and composition of combustion gases flowing inside long tubes are given. The rate of heat transfer from combustion gases to tube wall is to be determined.

Assumptions All the gases in the mixture are ideal gases.

Analysis The volumetric analysis of a gas mixture gives the mole fractions y_i of the components, which are equivalent to pressure fractions for an ideal gas mixture. Therefore, the partial pressures of CO_2 and H_2O are

$$P_c = y_{CO_2}P = 0.10(1\,\text{atm}) = 0.10\,\text{atm}$$

$$P_w = y_{H_2O}P = 0.10(1\,\text{atm}) = 0.10\,\text{atm}$$



The mean beam length for this geometry is, from Table 12-4,

$$L = 3.6V/A_s = 1.8D = 1.8(0.20\text{ m}) = 0.36\text{ m}$$

where D is the distance between the plates. Then,

$$P_cL = P_wL = (0.10\,\text{atm})(0.36\,\text{m}) = 0.036\,\text{m}\cdot\text{atm} = 0.118\,\text{ft}\cdot\text{atm}$$

The emissivities of CO_2 and H_2O corresponding to these values at the gas temperature of T_g = 1200 K and 1atm are, from Fig. 12-36,

$$\varepsilon_{c,1\,\text{atm}} = 0.080 \quad \text{and} \quad \varepsilon_{w,1\,\text{atm}} = 0.055$$

Both CO_2 and H_2O are present in the same mixture, and we need to correct for the overlap of emission bands. The emissivity correction factor at $T = T_g$ = 1200 K is, from Fig. 12-38,

$$\left.\begin{array}{l} P_cL + P_wL = 0.118 + 0.118 = 0.236 \\ \dfrac{P_w}{P_w + P_c} = \dfrac{0.10}{0.10 + 0.10} = 0.5 \end{array}\right\} \Delta\varepsilon = 0.0025$$

Then the effective emissivity of the combustion gases becomes

$$\varepsilon_g = C_c\varepsilon_{c,1\,\text{atm}} + C_w\varepsilon_{w,1\,\text{atm}} - \Delta\varepsilon = 1\times0.080 + 1\times0.055 - 0.0025 = 0.1325$$

Note that the pressure correction factor is 1 for both gases since the total pressure is 1 atm. For a source temperature of T_s = 600 K, the absorptivity of the gas is again determined using the emissivity charts as follows:

$$P_cL\frac{T_s}{T_g} = P_wL\frac{T_s}{T_g} = (0.10\,\text{atm})(0.36\,\text{m})\frac{600\,\text{K}}{1200\,\text{K}} = 0.018\,\text{m}\cdot\text{atm} = 0.059\,\text{ft}\cdot\text{atm}$$

The emissivities of CO_2 and H_2O corresponding to these values at a temperature of T_s = 600 K and 1atm are, from Fig. 12-36,

$$\varepsilon_{c,1\,\text{atm}} = 0.065 \quad \text{and} \quad \varepsilon_{w,1\,\text{atm}} = 0.067$$

Then the absorptivities of CO_2 and H_2O become

$$\alpha_c = C_c\left(\frac{T_g}{T_s}\right)^{0.65}\varepsilon_{c,1\,\text{atm}} = (1)\left(\frac{1200\,\text{K}}{600\,\text{K}}\right)^{0.65}(0.065) = 0.102$$

$$\alpha_w = C_w\left(\frac{T_g}{T_s}\right)^{0.45}\varepsilon_{w,1\,\text{atm}} = (1)\left(\frac{1200\,\text{K}}{600\,\text{K}}\right)^{0.45}(0.067) = 0.092$$

Also $\Delta\alpha = \Delta\varepsilon$, but the emissivity correction factor is to be evaluated from Fig. 12-38 at $T = T_s$ = 600 K instead of T_g = 1200 K. There is no chart for 600 K in the figure, but we can read $\Delta\varepsilon$ values at 400 K and 800 K, and take their average. At $P_w/(P_w + P_c)$ = 0.5 and $P_cL + P_wL$ = 0.236 we read $\Delta\varepsilon$ = 0.00125. Then the absorptivity of the combustion gases becomes

$$\alpha_g = \alpha_c + \alpha_w - \Delta\alpha = 0.102 + 0.092 - 0.00125 = 0.1928$$

Then the net rate of radiation heat transfer from the gas to each plate per unit surface area becomes

$$\begin{aligned} \dot{Q}_{\text{net}} &= A_s\sigma(\varepsilon_g T_g^4 - \alpha_g T_s^4) \\ &= (1\,\text{m}^2)(5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4)[0.1325(1200\,\text{K})^4 - 0.1928(600\,\text{K})^4] \\ &= \mathbf{1.42\times10^4\ W} \end{aligned}$$

Special Topic: Heat Transfer from the Human Body

12-74C Yes, roughly one-third of the metabolic heat generated by a person who is resting or doing light work is dissipated to the environment by convection, one-third by evaporation, and the remaining one-third by radiation.

12-75C Sensible heat is the energy associated with a temperature change. The sensible heat loss from a human body increases as (*a*) the skin temperature increases, (*b*) the environment temperature decreases, and (*c*) the air motion (and thus the convection heat transfer coefficient) increases.

12-76C Latent heat is the energy released as water vapor condenses on cold surfaces, or the energy absorbed from a warm surface as liquid water evaporates. The latent heat loss from a human body increases as (*a*) the skin wettedness increases and (*b*) the relative humidity of the environment decreases. The rate of evaporation from the body is related to the rate of latent heat loss by $\dot{Q}_{\text{latent}} = \dot{m}_{\text{vapor}} h_{fg}$ where h_{fg} is the latent heat of vaporization of water at the skin temperature.

12-77C The insulating effect of clothing is expressed in the unit **clo** with 1 clo = 0.155 $\text{m}^2.°\text{C/W}$ = 0.880 $\text{ft}^2.°\text{F.h/Btu}$. Clothing serves as insulation, and thus reduces heat loss from the body by convection, radiation, and evaporation by serving as a resistance against heat flow and vapor flow. Clothing decreases heat gain from the sun by serving as a radiation shield.

12-78C (*a*) Heat is lost through the skin by convection, radiation, and evaporation. (*b*) The body loses both sensible heat by convection and latent heat by evaporation from the lungs, but there is no heat transfer in the lungs by radiation.

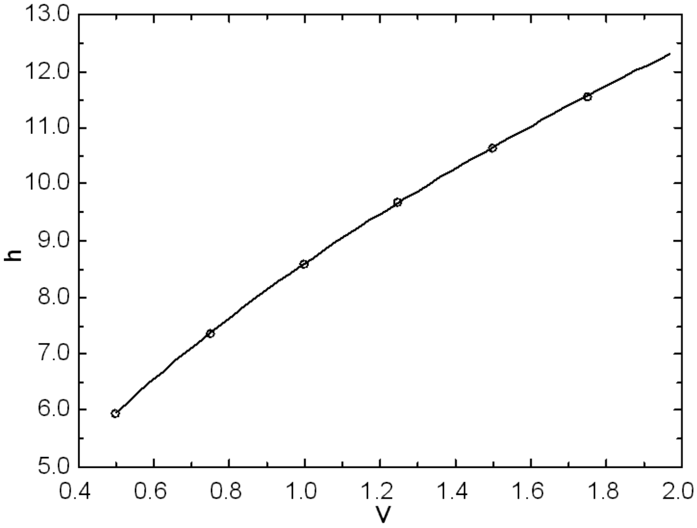
12-79C The *operative temperature* $T_{\text{operative}}$ is the average of the mean radiant and ambient temperatures weighed by their respective convection and radiation heat transfer coefficients, and is expressed as

$$T_{\text{operative}} = \frac{h_{\text{conv}} T_{\text{ambient}} + h_{\text{rad}} T_{\text{surr}}}{h_{\text{conv}} + h_{\text{rad}}} \cong \frac{T_{\text{ambient}} + T_{\text{surr}}}{2}$$

When the convection and radiation heat transfer coefficients are equal to each other, the operative temperature becomes the arithmetic average of the ambient and surrounding surface temperatures.

12-80 The convection heat transfer coefficient for a clothed person while walking in still air at a velocity of 0.5 to 2 m/s is given by $h = 8.6V^{0.53}$ where V is in m/s and h is in W/m^2.°C. The convection coefficients in that range vary from 5.96 W/m^2.°C at 0.5 m/s to 12.4 W/m^2.°C at 2 m/s. Therefore, at low velocities, the radiation and convection heat transfer coefficients are comparable in magnitude. But at high velocities, the convection coefficient is much larger than the radiation heat transfer coefficient.

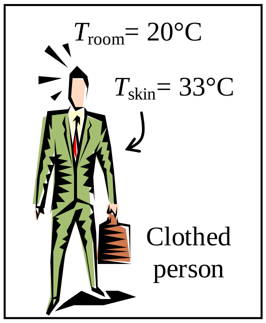
Velocity, m/s	$h = 8.6V^{0.53}$ W/m^2.°C
0.50	5.96
0.75	7.38
1.00	8.60
1.25	9.68
1.50	10.66
1.75	11.57
2.00	12.40



12-81 A man wearing summer clothes feels comfortable in a room at 22°C. The room temperature at which this man would feel thermally comfortable when unclothed is to be determined.

Assumptions **1** Steady conditions exist. **2** The latent heat loss from the person remains the same. **3** The heat transfer coefficients remain the same. **4** The air in the room is still (there are no winds or running fans). **5** The surface areas of the clothed and unclothed person are the same.

Analysis At low air velocities, the convection heat transfer coefficient for a standing man is given in Table 12-3 to be 4.0 W/m^2.°C. The radiation heat transfer coefficient at typical indoor conditions is 4.7 W/m^2.°C. Therefore, the heat transfer coefficient for a standing person for combined convection and radiation is



$$h_{\text{combined}} = h_{\text{conv}} + h_{\text{rad}} = 4.0 + 4.7 = 8.7 \text{ W/m}^2.°\text{C}$$

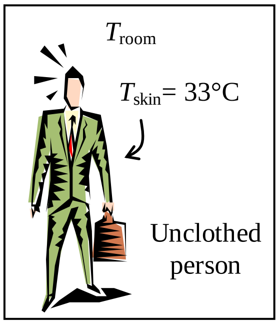
The thermal resistance of the clothing is given to be

$$R_{\text{cloth}} = 0.7 \text{ clo} = 0.7 \times 0.155 \text{ m}^2.°\text{C/W} = 0.109 \text{ m}^2.°\text{C/W}$$

Noting that the surface area of an average man is 1.8 m^2, the sensible heat loss from this person when clothed is determined to be

$$\dot{Q}_{\text{sensible,clothed}} = \frac{A_s(T_{\text{skin}} - T_{\text{ambient}})}{R_{\text{cloth}} + \dfrac{1}{h_{\text{combined}}}} = \frac{(1.8\text{ m}^2)(33-20)°\text{C}}{0.109\text{ m}^2.°\text{C/W} + \dfrac{1}{8.7\text{ W/m}^2.°\text{C}}} = 104\text{ W}$$

From heat transfer point of view, taking the clothes off is equivalent to removing the clothing insulation or setting R_{cloth} = 0. The heat transfer in this case can be expressed as



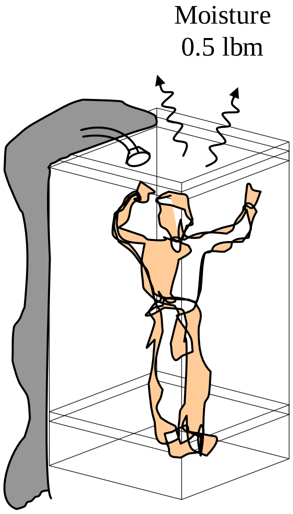
$$\dot{Q}_{\text{sensible,unclothed}} = \frac{A_s(T_{\text{skin}} - T_{\text{ambient}})}{\dfrac{1}{h_{\text{combined}}}} = \frac{(1.8\text{ m}^2)(33 - T_{\text{ambient}})°\text{C}}{\dfrac{1}{8.7\text{ W/m}^2.°\text{C}}}$$

To maintain thermal comfort after taking the clothes off, the skin temperature of the person and the rate of heat transfer from him must remain the same. Then setting the equation above equal to 104 W gives

$$T_{\text{ambient}} = \mathbf{26.4°\,C}$$

Therefore, the air temperature needs to be raised from 22 to 26.4°C to ensure that the person will feel comfortable in the room after he takes his clothes off. Note that the effect of clothing on latent heat is assumed to be negligible in the solution above. We also assumed the surface area of the clothed and unclothed person to be the same for simplicity, and these two effects should counteract each other.

12-82E An average person produces 0.50 lbm of moisture while taking a shower. The contribution of showers of a family of four to the latent heat load of the air-conditioner per day is to be determined.



Assumptions All the water vapor from the shower is condensed by the air-conditioning system.

Properties The latent heat of vaporization of water is given to be 1050 Btu/lbm.

Analysis The amount of moisture produced per day is

$$m_{\text{vapor}} = (\text{Moisture produced per person})(\text{No. of persons})$$
$$= (0.5\text{ lbm/person})(4\text{ persons/day}) = 2\text{ lbm/day}$$

Then the latent heat load due to showers becomes

$$Q_{\text{latent}} = m_{\text{vapor}}h_{fg} = (2\text{ lbm/day})(1050\text{ Btu/lbm}) = \mathbf{2100\ Btu/day}$$

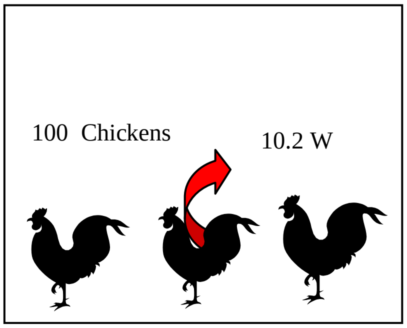
12-83 There are 100 chickens in a breeding room. The rate of total heat generation and the rate of moisture production in the room are to be determined.

Assumptions All the moisture from the chickens is condensed by the air-conditioning system.

Properties The latent heat of vaporization of water is given to be 2430 kJ/kg. The average metabolic rate of chicken during normal activity is 10.2 W (3.78 W sensible and 6.42 W latent).

Analysis The total rate of heat generation of the chickens in the breeding room is

$$\dot{Q}_{\text{gen, total}} = \dot{q}_{\text{gen, total}}(\text{No. of chickens})$$
$$= (10.2\text{ W/chicken})(100\text{ chickens}) = \mathbf{1020\ W}$$



The latent heat generated by the chicken and the rate of moisture production are

$$\dot{Q}_{\text{gen, latent}} = \dot{q}_{\text{gen, latent}}(\text{No. of chickens})$$
$$= (6.42\text{ W/chicken})(100\text{ chickens}) = 642\text{ W}$$
$$= 0.642\text{ kW}$$

$$\dot{m}_{\text{moisture}} = \frac{\dot{Q}_{\text{gen, latent}}}{h_{fg}} = \frac{0.642\text{ kJ/s}}{2430\text{ kJ/kg}} = 0.000264\text{ kg/s} = \mathbf{0.264\ g/s}$$

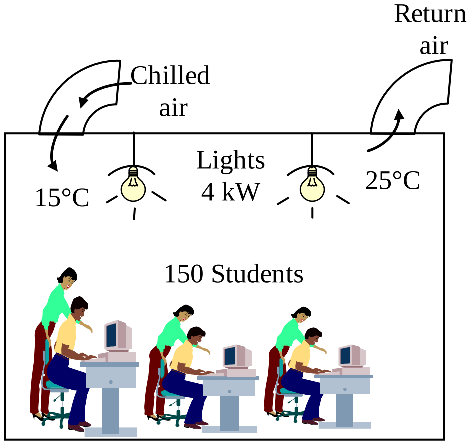
12-84 Chilled air is to cool a room by removing the heat generated in a large insulated classroom by lights and students. The required flow rate of air that needs to be supplied to the room is to be determined.

Assumptions **1** The moisture produced by the bodies leave the room as vapor without any condensing, and thus the classroom has no latent heat load. **2** Heat gain through the walls and the roof is negligible.

Properties The specific heat of air at room temperature is 1.00 kJ/kg·°C (Table A-15). The average rate of metabolic heat generation by a person sitting or doing light work is 115 W (70 W sensible, and 45 W latent).

Analysis The rate of sensible heat generation by the people in the room and the total rate of sensible internal heat generation are

$$\begin{aligned}\dot{Q}_{\text{gen, sensible}} &= \dot{q}_{\text{gen, sensible}}(\text{No. of people})\\ &= (70\text{ W/person})(150\text{ persons}) = 10{,}500\text{ W}\\ \dot{Q}_{\text{total, sensible}} &= \dot{Q}_{\text{gen, sensible}} + \dot{Q}_{\text{lighting}}\\ &= 10{,}500 + 4000 = 14{,}500\text{ W}\end{aligned}$$



Then the required mass flow rate of chilled air becomes

$$\begin{aligned}\dot{m}_{\text{air}} &= \frac{\dot{Q}_{\text{total, sensible}}}{C_p \Delta T}\\ &= \frac{14.5\text{ kJ/s}}{(1.0\text{ kJ/kg}\cdot{}^\circ\text{C})(25-15)^\circ\text{C}} = \mathbf{1.45\ kg/s}\end{aligned}$$

Discussion The latent heat will be removed by the air-conditioning system as the moisture condenses outside the cooling coils.

12-85 The average mean radiation temperature during a cold day drops to 18°C. The required rise in the indoor air temperature to maintain the same level of comfort in the same clothing is to be determined.

Assumptions **1** Air motion in the room is negligible. **2** The average clothing and exposed skin temperature remains the same. **3** The latent heat loss from the body remains constant. **4** Heat transfer through the lungs remain constant.

Properties The emissivity of the person is 0.95 (from Appendix tables). The convection heat transfer coefficient from the body in still air or air moving with a velocity under 0.2 m/s is h_{conv} = 3.1 W/m^2·°C (Table 12-3).

Analysis The total rate of heat transfer from the body is the sum of the rates of heat loss by convection, radiation, and evaporation,

$$\dot{Q}_{\text{body, total}} = \dot{Q}_{\text{sensible}} + \dot{Q}_{\text{latent}} + \dot{Q}_{\text{lungs}} = (\dot{Q}_{\text{conv}} + Q_{\text{rad}}) + \dot{Q}_{\text{latent}} + \dot{Q}_{\text{lungs}}$$

Noting that heat transfer from the skin by evaporation and from the lungs remains constant, the sum of the convection and radiation heat transfer from the person must remain constant.

$$\begin{aligned}\dot{Q}_{\text{sensible,old}} &= hA_s(T_s - T_{\text{air, old}}) + \varepsilon A_s\sigma(T_s^4 - T_{\text{surr,old}}^4)\\ &= hA_s(T_s - 22) + 0.95A_s\sigma[(T_s + 273)^4 - (22+273)^4]\\ \dot{Q}_{\text{sensible,new}} &= hA_s(T_s - T_{\text{air, new}}) + \varepsilon A_s\sigma(T_s^4 - T_{\text{surr,new}}^4)\\ &= hA_s(T_s - T_{\text{air, new}}) + 0.95A_s\sigma[(T_s + 273)^4 - (18+273)^4]\end{aligned}$$

Setting the two relations above equal to each other, canceling the surface area A_s, and simplifying gives

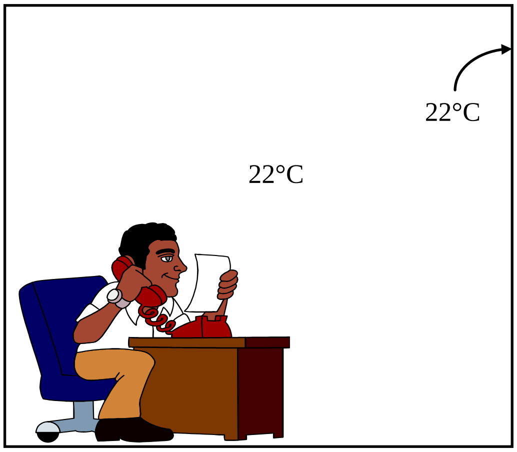
$$-22h - 0.95\sigma(22+273)^4 = -hT_{\text{air, new}} - 0.95\sigma(18+273)^4$$

$$3.1(T_{\text{air, new}} - 22) + 0.95 \times 5.67 \times 10^{-8}(291^4 - 295^4) = 0$$

Solving for the new air temperature gives

$$T_{\text{air, new}} = \mathbf{29.0°C}$$

Therefore, the air temperature must be raised to 29°C to counteract the increase in heat transfer by radiation.



12-86 The average mean radiation temperature during a cold day drops to 12°C. The required rise in the indoor air temperature to maintain the same level of comfort in the same clothing is to be determined.

Assumptions **1** Air motion in the room is negligible. **2** The average clothing and exposed skin temperature remains the same. **3** The latent heat loss from the body remains constant. **4** Heat transfer through the lungs remain constant.

Properties The emissivity of the person is 0.95 (from Appendix tables). The convection heat transfer coefficient from the body in still air or air moving with a velocity under 0.2 m/s is $h_{\text{conv}} = 3.1$ W/m^2·°C (Table 12-3).

Analysis The total rate of heat transfer from the body is the sum of the rates of heat loss by convection, radiation, and evaporation,

$$\dot{Q}_{\text{body, total}} = \dot{Q}_{\text{sensible}} + \dot{Q}_{\text{latent}} + \dot{Q}_{\text{lungs}} = (\dot{Q}_{\text{conv}} + Q_{\text{rad}}) + \dot{Q}_{\text{latent}} + \dot{Q}_{\text{lungs}}$$

Noting that heat transfer from the skin by evaporation and from the lungs remains constant, the sum of the convection and radiation heat transfer from the person must remain constant.

$$\begin{aligned}\dot{Q}_{\text{sensible,old}} &= hA_s(T_s - T_{\text{air, old}}) + \varepsilon A_s\sigma(T_s^4 - T_{\text{surr,old}}^4)\\ &= hA_s(T_s - 22) + 0.95A_s\sigma[(T_s + 273)^4 - (22+273)^4]\\ \dot{Q}_{\text{sensible,new}} &= hA_s(T_s - T_{\text{air, new}}) + \varepsilon A_s\sigma(T_s^4 - T_{\text{surr,new}}^4)\\ &= hA_s(T_s - T_{\text{air, new}}) + 0.95A_s\sigma[(T_s + 273)^4 - (12+273)^4]\end{aligned}$$

Setting the two relations above equal to each other, canceling the surface area A_s, and simplifying gives

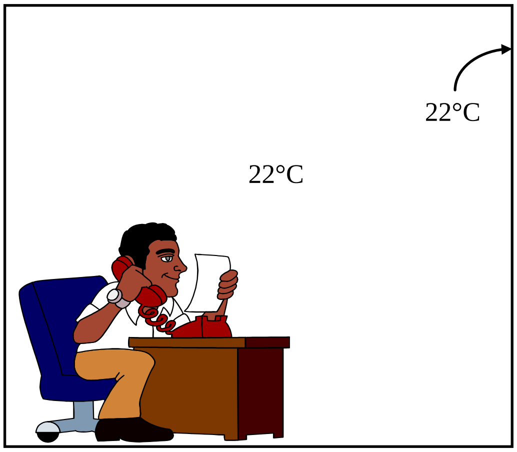
$$-22h - 0.95\sigma(22+273)^4 = -hT_{\text{air, new}} - 0.95\sigma(12+273)^4$$

$$3.1(T_{\text{air, new}} - 22) + 0.95\times 5.67\times 10^{-8}(285^4 - 295^4) = 0$$

Solving for the new air temperature gives

$$T_{\text{air, new}} = \mathbf{39.0°C}$$

Therefore, the air temperature must be raised to 39°C to counteract the increase in heat transfer by radiation.



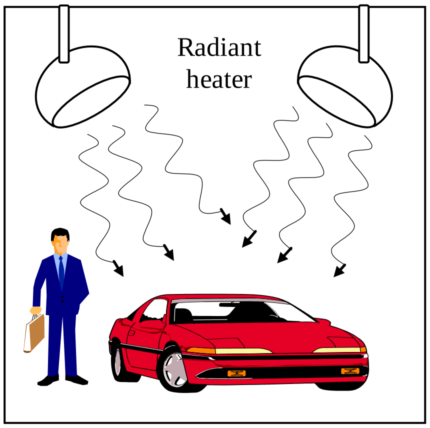
12-87 A car mechanic is working in a shop heated by radiant heaters in winter. The lowest ambient temperature the worker can work in comfortably is to be determined.

Assumptions **1** The air motion in the room is negligible, and the mechanic is standing. **2** The average clothing and exposed skin temperature of the mechanic is 33°C.

Properties The emissivity and absorptivity of the person is given to be 0.95. The convection heat transfer coefficient from a standing body in still air or air moving with a velocity under 0.2 m/s is h_{conv} = 4.0 W/m^2·°C (Table 12-3).

Analysis The equivalent thermal resistance of clothing is

$$R_{\text{cloth}} = 0.7\text{ clo} = 0.7\times 0.155\text{ m}^2.\text{°C/W} = 0.1085\text{ m}^2.\text{°C/W}$$



Radiation from the heaters incident on the person and the rate of sensible heat generation by the person are

$$\dot{Q}_{\text{rad, incident}} = 0.05\times\dot{Q}_{\text{rad, total}} = 0.05(10\text{ kW}) = 0.5\text{ kW} = 500\text{ W}$$
$$\dot{Q}_{\text{gen, sensible}} = 0.5\times\dot{Q}_{\text{gen, total}} = 0.5(350\text{ W}) = 175\text{ W}$$

Under steady conditions, and energy balance on the body can be expressed as

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_{\text{gen}} = 0$$
$$\dot{Q}_{\text{rad from heater}} - \dot{Q}_{\text{conv+rad from body}} + \dot{Q}_{\text{gen, sensible}} = 0$$

or

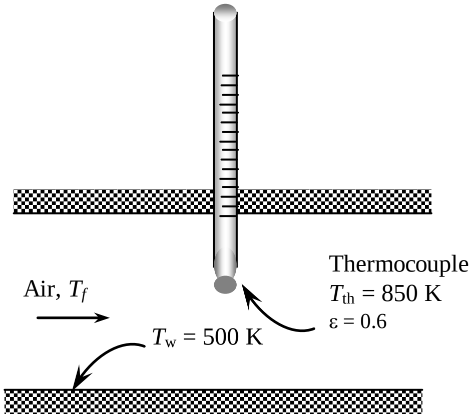
$$\alpha\dot{Q}_{\text{rad, incident}} - h_{\text{conv}}A_s(T_s - T_{\text{surr}}) - \varepsilon A_s\sigma(T_s^4 - T_{\text{surr}}^4) + \dot{Q}_{\text{gen, sensible}} = 0$$
$$0.95(500\text{ W}) - (4.0\text{ W/m}^2\cdot\text{K})(1.8\text{ m}^2)(306 - T_{\text{surr}})$$
$$-0.95(1.8\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[(306\text{ K})^4 - T_{\text{surr}}^4) + 175\text{ W} = 0$$

Solving the equation above gives

$$T_{\text{surr}} = 266.2\text{ K} = \mathbf{-7.0°C}$$

Therefore, the mechanic can work comfortably at temperatures as low as -7°C.

Review Problems



12-88 The temperature of air in a duct is measured by a thermocouple. The radiation effect on the temperature measurement is to be quantified, and the actual air temperature is to be determined.

Assumptions The surfaces are opaque, diffuse, and gray.

Properties The emissivity of thermocouple is given to be ε=0.6.

Analysis The actual temperature of the air can be determined from

$$T_f = T_{th} + \frac{\varepsilon_{th}\sigma(T_{th}^4 - T_w^4)}{h}$$

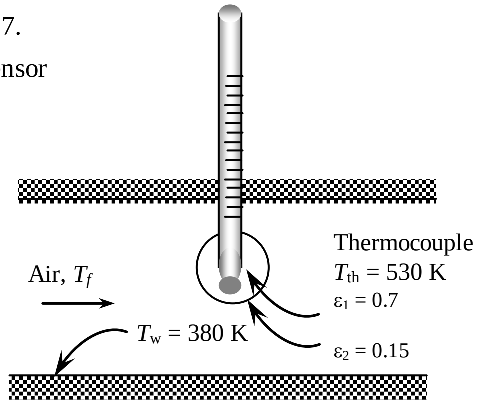
$$= 850\text{ K} + \frac{(0.6)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[(850\text{ K})^4 - (500\text{ K})^4]}{60\text{ W/m}^2\cdot{}^\circ\text{C}} = \mathbf{1111 K}$$

12-89 The temperature of hot gases in a duct is measured by a thermocouple. The actual temperature of the gas is to be determined, and compared with that without a radiation shield.

Assumptions The surfaces are opaque, diffuse, and gray.

Properties The emissivity of the thermocouple is given to be ε =0.7.

Analysis Assuming the area of the shield to be very close to the sensor of the thermometer, the radiation heat transfer from the sensor is determined from



$$\dot{Q}_{\text{rad, from sensor}} = \frac{\sigma(T_1^4 - T_2^4)}{\left(\frac{1}{\varepsilon_1} - 1\right) + \left(2\frac{1}{\varepsilon_2} - 1\right)}$$

$$= \frac{(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[(530\text{ K})^4 - (380\text{ K})^4]}{\left(\frac{1}{0.7} - 1\right) + \left(2\frac{1}{0.15} - 1\right)}$$

$$= 257.9\text{ W/m}^2$$

Then the actual temperature of the gas can be determined from a heat transfer balance to be

$$\dot{q}_{\text{conv,to sensor}} = \dot{q}_{\text{conv,from sensor}}$$

$$h(T_f - T_{th}) = 257.9\text{ W/m}^2$$

$$120\text{ W/m}^2\cdot{}^\circ\text{C}(T_f - 530) = 257.9\text{ W/m}^2 \longrightarrow T_f = \mathbf{532 K}$$

Without the shield the temperature of the gas would be

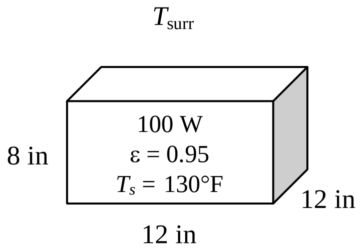
$$T_f = T_{th} + \frac{\varepsilon_{th}\sigma(T_{th}^4 - T_w^4)}{h}$$

$$= 530\text{ K} + \frac{(0.7)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[(530\text{ K})^4 - (380\text{ K})^4]}{120\text{ W/m}^2\cdot{}^\circ\text{C}} = \mathbf{549.2 K}$$

12-90E A sealed electronic box is placed in a vacuum chamber. The highest temperature at which the surrounding surfaces must be kept if this box is cooled by radiation alone is to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered. **4** Heat transfer from the bottom surface of the box is negligible.

Properties The emissivity of the outer surface of the box is ε = 0.95.



Analysis The total surface area is

$$A_s = 4\times(8\times1/12)+(1\times1) = 3.67\ \text{ft}^2$$

Then the temperature of the surrounding surfaces is determined to be

$$\dot{Q}_{rad} = \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$

$$(100\times3.41214)\ \text{Btu/h} = (0.95)(3.67\ \text{m}^2)(0.1714\times10^{-8}\ \text{Btu/h.ft}^2\cdot\text{R}^4)[(590\ \text{R})^4 - T_{surr}{}^4]$$

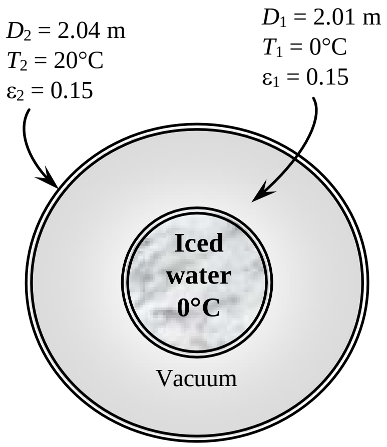
$$\longrightarrow T_{surr} = 503\ \text{R} = \mathbf{43°F}$$

12-91 A double-walled spherical tank is used to store iced water. The air space between the two walls is evacuated. The rate of heat transfer to the iced water and the amount of ice that melts a 24-h period are to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray.

Properties The emissivities of both surfaces are given to be $\varepsilon_1 = \varepsilon_2 = 0.15$.

Analysis (*a*) Assuming the conduction resistance s of the walls to be negligible, the rate of heat transfer to the iced water in the tank is determined to be



$$A_1 = \pi D_1{}^2 = \pi(2.01\ \text{m})^2 = 12.69\ \text{m}^2$$

$$\dot{Q}_{12} = \frac{A_1\sigma(T_2{}^4 - T_1{}^4)}{\dfrac{1}{\varepsilon_1}+\dfrac{1-\varepsilon_2}{\varepsilon_2}\left(\dfrac{D_1}{D_2}\right)^2}$$

$$= \frac{(12.69\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(20+273\ \text{K})^4-(0+273\ \text{K})^4]}{\dfrac{1}{0.15}+\dfrac{1-0.15}{0.15}\left(\dfrac{2.01}{2.04}\right)^2}$$

$$= \mathbf{107.4\ W}$$

(*b*) The amount of heat transfer during a 24-hour period is

$$Q = \dot{Q}\Delta t = (0.1074\ \text{kJ/s})(24\times3600\ \text{s}) = 9275\ \text{kJ}$$

The amount of ice that melts during this period then becomes

$$Q = mh_{if} \longrightarrow m = \frac{Q}{h_{if}} = \frac{9275\ \text{kJ}}{333.7\ \text{kJ/kg}} = \mathbf{27.8\ kg}$$

12-92 Two concentric spheres which are maintained at uniform temperatures are separated by air at 1 atm pressure. The rate of heat transfer between the two spheres by natural convection and radiation is to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Air is an ideal gas with constant properties.

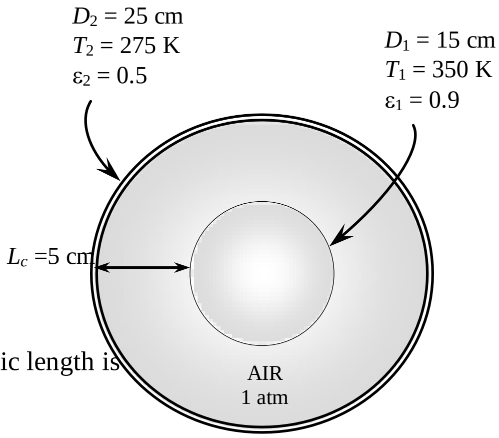
Properties The emissivities of the surfaces are given to be $\varepsilon_1 = \varepsilon_2 = 0.5$. The properties of air at 1 atm and the average temperature of $(T_1+T_2)/2 = (350+275)/2 = 312.5$ K = 39.5°C are (Table A-15)

$$k = 0.02658 \text{ W/m.°C}$$

$$\upsilon = 1.697\times10^{-5} \text{ m}^2\text{/s}$$

$$\text{Pr} = 0.7256$$

$$\beta = \frac{1}{312.5\text{ K}} = 0.0032 \text{ K}^{-1}$$



Analysis (*a*) Noting that $D_i = D_1$ and $D_o = D_2$, the characteristic length is

$$L_c = \frac{1}{2}(D_o - D_i) = \frac{1}{2}(0.25\text{ m} - 0.15\text{ m}) = 0.05\text{ m}$$

Then

$$Ra = \frac{g\beta(T_1 - T_2)L_c^3}{\upsilon^2}\text{Pr} = \frac{(9.81\text{ m/s}^2)(0.003200\text{ K}^{-1})(350 - 275\text{ K})(0.05\text{ m})^3}{(1.697\times10^{-5}\text{ m}^2\text{/s})^2}(0.7256) = 7.415\times10^5$$

The effective thermal conductivity is

$$F_{\text{sph}} = \frac{L_c}{(D_i D_o)^4 (D_i^{-7/5} + D_o^{-7/5})^5} = \frac{0.05\text{ m}}{\left[(0.15\text{ m})(0.25\text{ m})\right]^4\left[(0.15\text{ m})^{-7/5} + (0.25\text{ m})^{-7/5}\right]^5} = 0.005900$$

$$k_{\text{eff}} = 0.74k\left(\frac{\text{Pr}}{0.861 + \text{Pr}}\right)^{1/4}(F_{sph}Ra)^{1/4}$$

$$= 0.74(0.02658\text{ W/m.°C})\left(\frac{0.7256}{0.861 + 0.7256}\right)^{1/4}\left[(0.00590)(7.415\times10^5)\right]^{1/4} = 1315\text{ W/m.°C}$$

Then the rate of heat transfer between the spheres becomes

$$\dot{Q} = k_{\text{eff}}\,\pi\left(\frac{D_i D_o}{L_c}\right)(T_i - T_o) = (0.1315\text{ W/m.°C})\pi\left[\frac{(0.15\text{ m})(0.25\text{ m})}{(0.05\text{ m})}\right](350 - 275)\text{K} = \mathbf{23.3\ W}$$

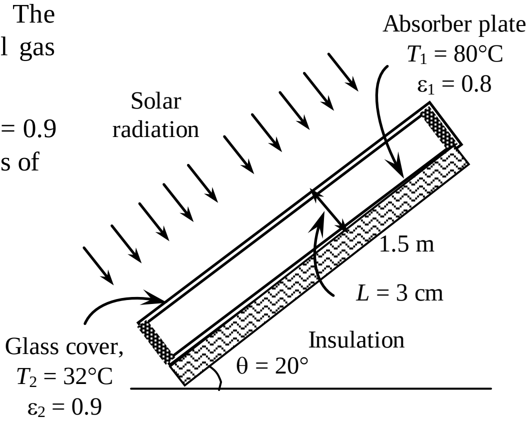
(*b*) The rate of heat transfer by radiation is determined from

$$A_1 = \pi D_1^{\,2} = \pi(0.15\text{ m})^2 = 0.0707\text{ m}^2$$

$$\dot{Q}_{12} = \frac{A_1\sigma(T_2^{\,4} - T_1^{\,4})}{\dfrac{1}{\varepsilon_1} + \dfrac{1-\varepsilon_2}{\varepsilon_2}\left(\dfrac{D_1}{D_2}\right)^2} = \frac{(0.0707\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[(350\text{ K})^4 - (275\text{ K})^4]}{\dfrac{1}{0.9} + \dfrac{1-0.9}{0.9}\left(\dfrac{0.15}{0.25}\right)^2} = \mathbf{32.3\ W}$$

12-93 A solar collector is considered. The absorber plate and the glass cover are maintained at uniform temperatures, and are separated by air. The rate of heat loss from the absorber plate by natural convection and radiation is to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Air is an ideal gas with constant properties.



Properties The emissivities of surfaces are given to be $\varepsilon_1 = 0.9$ for glass and $\varepsilon_2 = 0.8$ for the absorber plate. The properties of air at 1 atm and the average temperature of $(T_1+T_2)/2 = (80+32)/2 = 56°\text{C}$ are (Table A-15)

$$k = 0.02779\ \text{W/m.°C}$$

$$\upsilon = 1.857\times10^{-5}\ \text{m}^2/\text{s}$$

$$\text{Pr} = 0.7212$$

$$\beta = \frac{1}{T_f} = \frac{1}{(56+273)\text{K}} = 0.003040\ \text{K}^{-1}$$

Analysis For $\theta = 0°$, we have horizontal rectangular enclosure. The characteristic length in this case is the distance between the two glasses $L_c = L = 0.03$ m Then,

$$Ra = \frac{g\beta(T_1-T_2)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81\ \text{m/s}^2)(0.00304\ \text{K}^{-1})(80-32\ \text{K})(0.03\ \text{m})^3}{(1.857\times10^{-5}\ \text{m}^2/\text{s})^2}(0.7212) = 8.083\times10^4$$

$$A_s = H\times W = (1.5\ \text{m})(3\ \text{m}) = 4.5\ \text{m}^2$$

$$\text{Nu} = 1+1.44\left[1-\frac{1708}{\text{Ra}\cos\theta}\right]^+\left[1-\frac{1708(\sin 1.8\theta)^{1.6}}{\text{Ra}\cos\theta}\right]+\left[\frac{(\text{Ra}\cos\theta)^{1/3}}{18}-1\right]^+$$

$$= 1+1.44\left[1-\frac{1708}{(8.083\times10^4)\cos(20)}\right]^+\left[1-\frac{1708[\sin(1.8\times20)]^{1.6}}{(8.083\times10^4)\cos(20)}\right]+\left[\frac{[(8.083\times10^4)\cos(20)]^{1/3}}{18}-1\right]^+$$

$$= 3.747$$

$$\dot{Q} = kNuA_s\frac{T_1-T_2}{L} = (0.02779\ \text{W/m.°C})(3.747)(4.5\ \text{m}^2)\frac{(80-32)°\text{C}}{0.03\ \text{m}} = \mathbf{750\ W}$$

Neglecting the end effects, the rate of heat transfer by radiation is determined from

$$\dot{Q}_\text{rad} = \frac{A_s\sigma(T_1{}^4-T_2{}^4)}{\dfrac{1}{\varepsilon_1}+\dfrac{1}{\varepsilon_2}-1} = \frac{(4.5\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(80+273\ \text{K})^4-(32+273\ \text{K})^4]}{\dfrac{1}{0.8}+\dfrac{1}{0.9}-1} = \mathbf{1289\ W}$$

Discussion The rates of heat loss by natural convection for the horizontal and vertical cases would be as follows (Note that the Ra number remains the same):

Horizontal:

$$\text{Nu} = 1+1.44\left[1-\frac{1708}{\text{Ra}}\right]^+ + \left[\frac{\text{Ra}^{1/3}}{18}-1\right]^+ = 1+1.44\left[1-\frac{1708}{8.083\times10^4}\right]^+ + \left[\frac{(8.083\times10^4)^{1/3}}{18}-1\right]^+ = 3.812$$

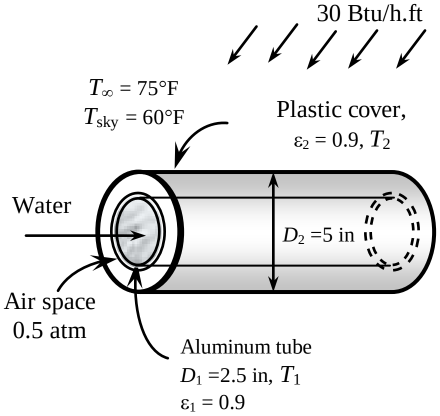
$$\dot{Q} = kNuA_s\frac{T_1-T_2}{L} = (0.02779\ \text{W/m.°C})(3.812)(6\ \text{m}^2)\frac{(80-32)°\text{C}}{0.03\ \text{m}} = \mathbf{1017\ W}$$

Vertical:

$$Nu = 0.42Ra^{1/4}\ \mathrm{Pr}^{0.012}\left(\frac{H}{L}\right)^{-0.3} = 0.42(8.083\times10^4)^{1/4}(0.7212)^{0.012}\left(\frac{2\ \mathrm{m}}{0.03\ \mathrm{m}}\right)^{-0.3} = 2.001$$

$$\dot{Q} = kNuA_s\frac{T_1 - T_2}{L} = (0.02779\ \mathrm{W/m.^\circ C})(2.001)(6\ \mathrm{m}^2)\frac{(80-32)^\circ\mathrm{C}}{0.03\ \mathrm{m}} = \mathbf{534\ W}$$

12-94E The circulating pump of a solar collector that consists of a horizontal tube and its glass cover fails. The equilibrium temperature of the tube is to be determined.



Assumptions **1** Steady operating conditions exist. **2** The tube and its cover are isothermal. **3** Air is an ideal gas. **4** The surfaces are opaque, diffuse, and gray for infrared radiation. **5** The glass cover is transparent to solar radiation.

Properties The properties of air should be evaluated at the average temperature. But we do not know the exit temperature of the air in the duct, and thus we cannot determine the bulk fluid and glass cover temperatures at this point, and thus we cannot evaluate the average temperatures. Therefore, we will assume the glass temperature to be 85°F, and use properties at an anticipated average temperature of (75+85)/2 =80°F (Table A-15E),

$$k = 0.01481 \text{ Btu/h}\cdot\text{ft}\cdot°\text{F}$$
$$\upsilon = 0.6110 \text{ ft}^2\text{/h} = 1.697\times10^{-4} \text{ ft}^2/s$$
$$\text{Pr} = 0.7290$$
$$\beta = \frac{1}{T_{\text{ave}}} = \frac{1}{540 \text{ R}}$$

Analysis We have a horizontal cylindrical enclosure filled with air at 0.5 atm pressure. The problem involves heat transfer from the aluminum tube to the glass cover and from the outer surface of the glass cover to the surrounding ambient air. When steady operation is reached, these two heat transfer rates must equal the rate of heat gain. That is,

$$\dot{Q}_{\text{tube-glass}} = \dot{Q}_{\text{glass-ambient}} = \dot{Q}_{\text{solar gain}} = 30 \text{ Btu/h} \qquad \text{(per foot of tube)}$$

The heat transfer surface area of the glass cover is

$$A_o = A_{glass} = (\pi D_o W) = \pi(5/12 \text{ ft})(1 \text{ ft}) = 1.309 \text{ ft}^2 \quad \text{(per foot of tube)}$$

To determine the Rayleigh number, we need to know the surface temperature of the glass, which is not available. Therefore, solution will require a trial-and-error approach. Assuming the glass cover temperature to be 85°F, the Rayleigh number, the Nusselt number, the convection heat transfer coefficient, and the rate of natural convection heat transfer from the glass cover to the ambient air are determined to be

$$\begin{aligned}\text{Ra}_{Do} &= \frac{g\beta(T_o - T_\infty)D_o^3}{\nu^2}\text{Pr}\\ &= \frac{(32.2 \text{ ft/s}^2)[1/(540 \text{ R})](85-75 \text{ R})(5/12 \text{ ft})^3}{(1.675\times10^{-4} \text{ ft}^2\text{/s})^2}(0.7290) = 1.092\times10^6\end{aligned}$$

$$\begin{aligned}\text{Nu} &= \left\{0.6 + \frac{0.387 \,\text{Ra}_\text{D}^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6 + \frac{0.387(1.092\times10^6)^{1/6}}{\left[1+(0.559/0.7290)^{9/16}\right]^{8/27}}\right\}^2\\ &= 14.95\end{aligned}$$

$$h_o = \frac{k}{D_0}\text{Nu} = \frac{0.01481 \text{ Btu/h}\cdot\text{ft}\cdot°\text{F}}{5/12 \text{ ft}}(14.95) = 0.5315 \text{ Btu/h}\cdot\text{ft}^2\cdot°\text{F}$$

$$\dot{Q}_{o,\text{conv}} = h_o A_o (T_o - T_\infty) = (0.5315 \text{ Btu/h}\cdot\text{ft}^2\cdot°\text{F})(1.309 \text{ ft}^2)(85-75)°\text{F} = 6.96 \text{ Btu/h}$$

Also,

$$\begin{aligned}\dot{Q}_{o,\text{rad}} &= \varepsilon_o \sigma A_o (T_o^4 - T_{\text{sky}}^4)\\ &= (0.9)(0.1714\times10^{-8}\ \text{Btu/h}\cdot\text{ft}^2\cdot\text{R}^4)(1.309\ \text{ft}^2)\left[(545\ \text{R})^4-(535\ \text{R})^4\right]\\ &= 30.5\ \text{Btu/h}\end{aligned}$$

Then the total rate of heat loss from the glass cover becomes

$$\dot{Q}_{o,\text{total}} = \dot{Q}_{o,\text{conv}} + \dot{Q}_{o,\text{rad}} = 7.0 + 30.5 = 37.5\ \text{Btu/h}$$

which is more than 30 Btu/h. Therefore, the assumed temperature of 85°F for the glass cover is high. Repeating the calculations with lower temperatures (including the evaluation of properties), the glass cover temperature corresponding to 30 Btu/h is determined to be **81.5°F**.

The temperature of the aluminum tube is determined in a similar manner using the natural convection and radiation relations for two horizontal concentric cylinders. The characteristic length in this case is the distance between the two cylinders, which is

$$L_c = (D_o - D_i)/2 = (5-2.5)/2 = 1.25\ \text{in} = 1.25/12\ \text{ft}$$

Also,

$$A_i = A_{tube} = (\pi D_i W) = \pi(2.5/12\ \text{ft})(1\ \text{ft}) = 0.6545\ \text{ft}^2 \quad \text{(per foot of tube)}$$

We start the calculations by assuming the tube temperature to be 118.5°F, and thus an average temperature of (81.5+118.5)/2 = 100°F=640 R. Using properties at 100°F,

$$\text{Ra}_L = \frac{g\beta(T_i - T_o)L^3}{\nu^2}\Pr = \frac{(32.2\ \text{ft/s}^2)[1/(640\ \text{R})](118.5-81.5\ \text{R})(1.25/12\ \text{ft})^3}{(1.809\times10^{-4}\ \text{ft}^2\text{/s})^2}(0.726) = 1.334\times10^4$$

The effective thermal conductivity is

$$F_{\text{cyc}} = \frac{[\ln(D_o/D_i)]^4}{L_c^3(D_i^{-3/5}+D_o^{-3/5})^5} = \frac{[\ln(5/2.5)]^4}{(1.25/12\ \text{ft})^3[(2.5/12\ \text{ft})^{-3/5}+(5/12\ \text{ft})^{-3/5}]^5} = 0.1466$$

$$\begin{aligned}k_{\text{eff}} &= 0.386k\left(\frac{\Pr}{0.861+\Pr}\right)^{1/4}(F_{\text{cyc}}\text{Ra}_L)^{1/4}\\ &= 0.386(0.01529\ \text{Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F})\left(\frac{0.726}{0.861+0.726}\right)(0.1466\times1.334\times10^4)^{1/4}\\ &= 0.03227\ \text{Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}\end{aligned}$$

Then the rate of heat transfer between the cylinders by convection becomes

$$\dot{Q}_{i,\text{conv}} = \frac{2\pi k_{\text{eff}}}{\ln(D_o/D_i)}(T_i - T_o) = \frac{2\pi(0.03227\ \text{Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F})}{\ln(5/2.5)}(118.5-81.5)^\circ\text{F} = 10.8\ \text{Btu/h}$$

Also,

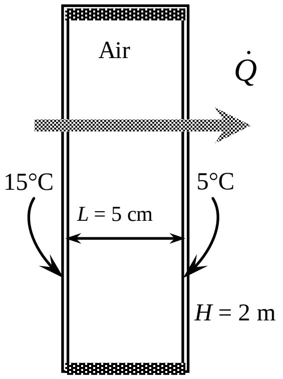
$$\dot{Q}_{i,\text{rad}} = \frac{\sigma A_i(T_i^4 - T_o^4)}{\dfrac{1}{\varepsilon_i}+\dfrac{1-\varepsilon_o}{\varepsilon_o}\left(\dfrac{D_i}{D_o}\right)} = \frac{(0.1714\times10^{-8}\ \text{Btu/h}\cdot\text{ft}^2\cdot\text{R}^4)(0.6545\ \text{ft}^2)\left[(578.5\ \text{R})^4-(541.5\ \text{R})^4\right]}{\dfrac{1}{0.9}+\dfrac{1-0.9}{0.9}\left(\dfrac{2.5\ \text{in}}{5\ \text{in}}\right)} = 25.0\ \text{Btu/h}$$

Then the total rate of heat loss from the glass cover becomes

$$\dot{Q}_{i,\text{total}} = \dot{Q}_{i,\text{conv}} + \dot{Q}_{i,\text{rad}} = 10.8 + 25.0 = 35.8\ \text{Btu/h}$$

which is more than 30 Btu/h. Therefore, the assumed temperature of 118.5°F for the tube is high. By trying other values, the tube temperature corresponding to 30 Btu/h is determined to be **113.2°F**. Therefore, the tube will reach an equilibrium temperature of 113.2°F when the pump fails.

12-95 A double-pane window consists of two sheets of glass separated by an air space. The rates of heat transfer through the window by natural convection and radiation are to be determined.



Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Air is an ideal gas with constant specific heats. **4** Heat transfer through the window is one-dimensional and the edge effects are negligible.

Properties The emissivities of glass surfaces are given to be $\varepsilon_1 = \varepsilon_2 = 0.9$. The properties of air at 0.3 atm and the average temperature of $(T_1+T_2)/2 = (15+5)/2 = 10°\text{C}$ are (Table A-15)

$$k = 0.02439 \text{ W/m.°C}$$

$$\upsilon = \upsilon_{1atm} / 0.3 = 1.426\times10^{-5}/0.3 = 4.753\times10^{-5} \text{ m}^2\text{/s}$$

$$\text{Pr} = 0.7336$$

$$\beta = \frac{1}{(10+273)\text{ K}} = 0.003534 \text{ K}^{-1}$$

Analysis The characteristic length in this case is the distance between the glasses, $L_c = L = 0.05 \text{ m}$

$$Ra = \frac{g\beta(T_1 - T_2)L^3}{\upsilon^2}\text{Pr} = \frac{(9.81 \text{ m/s}^2)(0.003534 \text{ K}^{-1})(15-5)\text{K}(0.05 \text{ m})^3}{(4.753\times10^{-5} \text{ m}^2\text{/s})^2}(0.7336) = 1.918\times10^4$$

$$Nu = 0.197Ra^{1/4}\left(\frac{H}{L}\right)^{-1/9} = 0.197(1.918\times10^4)^{1/4}\left(\frac{2}{0.05}\right)^{-1/9} = 1.539$$

$$A_s = (2 \text{ m})(3 \text{ m}) = 6 \text{ m}^2$$

Then the rate of heat transfer by natural convection becomes

$$\dot{Q}_{conv} = kNuA_s\frac{T_1 - T_2}{L} = (0.02439 \text{ W/m.°C})(1.539)(6 \text{ m}^2)\frac{(15-5)\text{°C}}{0.05 \text{ m}} = \mathbf{45.0\ W}$$

The rate of heat transfer by radiation is determined from

$$\dot{Q}_{\text{rad}} = \frac{A_s\sigma(T_1{}^4 - T_2{}^4)}{\dfrac{1}{\varepsilon_1}+\dfrac{1}{\varepsilon_2}-1}$$

$$= \frac{(6 \text{ m}^2)(5.67\times10^{-8} \text{ W/m}^2\cdot\text{K}^4)[(15+273 \text{ K})^4 - (5+273 \text{ K})^4]}{\dfrac{1}{0.9}+\dfrac{1}{0.9}-1}$$

$$= \mathbf{252\ W}$$

Then the rate of total heat transfer becomes

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad} = 45 + 252 = \mathbf{297\ W}$$

Discussion Note that heat transfer through the window is mostly by radiation.

12-96 A simple solar collector is built by placing a clear plastic tube around a garden hose. The rate of heat loss from the water in the hose by natural convection and radiation is to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Air is an ideal gas with constant specific heats.

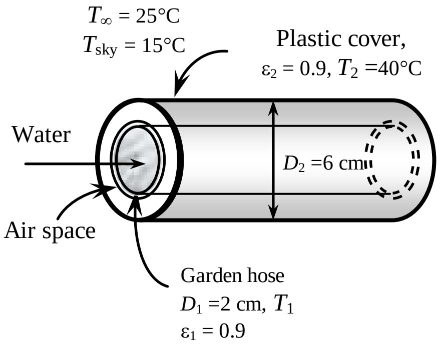
Properties The emissivities of surfaces are given to be $\varepsilon_1 = \varepsilon_2 = 0.9$. The properties of air are at 1 atm and the film temperature of $(T_s+T_\infty)/2 = (40+25)/2 = 32.5$°C are (Table A-15)

$$k = 0.02607\ \text{W/m.°C}$$

$$\upsilon = 1.632\times10^{-5}\ \text{m}^2\text{/s}$$

$$\text{Pr} = 0.7275$$

$$\beta = \frac{1}{(32.5+273)\ \text{K}} = 0.003273\ \text{K}^{-1}$$



Analysis Under steady conditions, the heat transfer rate from the water in the hose equals to the rate of heat loss from the clear plastic tube to the surroundings by natural convection and radiation. The characteristic length in this case is the diameter of the plastic tube, $L_c = D_{plastic} = D_2 = 0.06\ \text{m}$.

$$Ra = \frac{g\beta(T_s - T_\infty)D_2^3}{\upsilon^2}\text{Pr} = \frac{(9.81\ \text{m/s}^2)(0.003273\ \text{K}^{-1})(40-25)\text{K}(0.06\ \text{m})^3}{(1.632\times10^{-5}\ \text{m}^2\text{/s})^2}(0.7275) = 2.842\times10^5$$

$$\text{Nu} = \left\{0.6 + \frac{0.387\ \text{Ra}_\text{D}^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6 + \frac{0.387(2.842\times10^5)^{1/6}}{\left[1+(0.559/0.7241)^{9/16}\right]^{8/27}}\right\}^2 = 10.30$$

$$h = \frac{k}{D_2}Nu = \frac{0.02607\ \text{W/m.°C}}{0.06\ \text{m}}(10.30) = 4.475\ \text{W/m}^2\text{.°C}$$

$$A_{plastic} = A_2 = \pi D_2 L = \pi(0.06\ \text{m})(1\ \text{m}) = 0.1885\ \text{m}^2$$

Then the rate of heat transfer from the outer surface by natural convection becomes

$$\dot{Q}_{conv} = hA_2(T_s - T_\infty) = (4.475\ \text{W/m}^2\text{.°C})(0.1885\ \text{m}^2)(40-25)\text{°C} = \mathbf{12.7\ W}$$

The rate of heat transfer by radiation from the outer surface is determined from

$$\begin{aligned}\dot{Q}_\text{rad} &= \varepsilon A_2\sigma(T_s{}^4 - T_{sky}{}^4)\\ &= (0.90)(0.1885\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(40+273\ \text{K})^4 - (15+273\ \text{K})^4]\\ &= \mathbf{26.2\ W}\end{aligned}$$

Finally,

$$\dot{Q}_{total,loss} = 12.7 + 26.2 = 38.9\ \text{W}$$

Discussion Note that heat transfer is mostly by radiation.

12-97 A solar collector consists of a horizontal copper tube enclosed in a concentric thin glass tube. The annular space between the copper and the glass tubes is filled with air at 1 atm. The rate of heat loss from the collector by natural convection and radiation is to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Air is an ideal gas with constant specific heats.

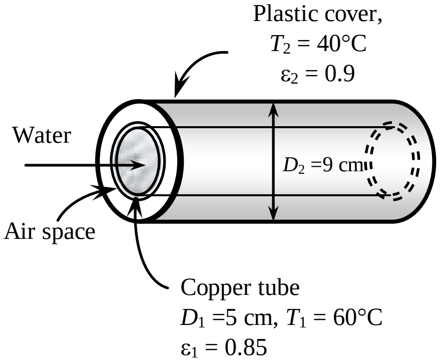
Properties The emissivities of surfaces are given to be ε_1 = 0.85 for the tube surface and ε_2 = 0.9 for glass cover. The properties of air at 1 atm and the average temperature of $(T_1+T_2)/2$ = (60+40)/2 = 50°C are (Table A-15)

$$k = 0.02735 \text{ W/m.°C}$$

$$\upsilon = 1.798\times10^{-5} \text{ m}^2\text{/s}$$

$$\text{Pr} = 0.7228$$

$$\beta = \frac{1}{(50+273)\text{ K}} = 0.003096 \text{ K}^{-1}$$



Analysis The characteristic length in this case is

$$L_c = \frac{1}{2}(D_2 - D_1) = \frac{1}{2}(0.09\text{ m - }0.05\text{ m}) = 0.02\text{ m}$$

$$Ra = \frac{g\beta(T_1 - T_2)L_c^3}{\upsilon^2}\text{Pr} = \frac{(9.81\text{ m/s}^2)(0.003096\text{ K}^{-1})(60-40)\text{K}(0.02\text{ m})^3}{(1.798\times10^{-5}\text{ m}^2\text{/s})^2}(0.7228) = 10{,}850$$

The effective thermal conductivity is

$$F_{\text{cyl}} = \frac{[\ln(D_o/D_i)]^4}{L_c^3(D_i^{-3/5} + D_o^{-3/5})^5} = \frac{[\ln(0.09/0.05)]^4}{(0.02\text{ m})^3\left[(0.09\text{ m})^{-3/5} + (0.05\text{ m})^{-3/5}\right]^5} = 0.1303$$

$$k_{\text{eff}} = 0.386k\left(\frac{\text{Pr}}{0.861+\text{Pr}}\right)^{1/4}(F_{\text{cyl}}\text{Ra})^{1/4}$$

$$= 0.386(0.02735\text{ W/m.°C})\left(\frac{0.7228}{0.861+0.7228}\right)^{1/4}\left[(0.1303)(10{,}850)\right]^{1/4} = 0.05321\text{ W/m.°C}$$

Then the rate of heat transfer between the cylinders becomes

$$\dot{Q}_{\text{conv}} = \frac{2\pi k_{\text{eff}}}{\ln(D_o/D_i)}(T_i - T_o) = \frac{2\pi(0.05321\text{ W/m.°C})}{\ln(0.09/0.05)}(60-40)\text{°C} = \mathbf{11.4\ W} \qquad \text{(Eq. 1)}$$

The rate of heat transfer by radiation is determined from

$$\dot{Q}_{\text{rad}} = \frac{A_1\sigma(T_1^4 - T_2^4)}{\frac{1}{\varepsilon_1} + \frac{1-\varepsilon_2}{\varepsilon_2}\left(\frac{D_1}{D_2}\right)}$$

$$= \frac{(0.1571\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[(60+273\text{ K})^4 - (40+273\text{ K})^4]}{\frac{1}{0.85} + \frac{1-0.9}{0.9}\left(\frac{5}{9}\right)}$$

$$= \mathbf{13.4\ W}$$

Finally,

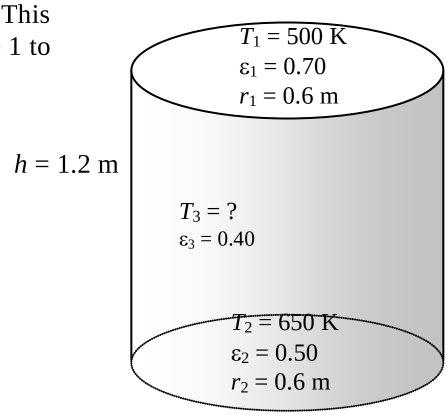
$$\dot{Q}_{total,loss} = 11.4 + 13.4 = 24.8\text{ W} \quad \text{(per m length)}$$

12-98 A cylindrical furnace with specified top and bottom surface temperatures and specified heat transfer rate at the bottom surface is considered. The temperature of the side surface and the net rates of heat transfer between the top and the bottom surfaces, and between the bottom and the side surfaces are to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivities of the top, bottom, and side surfaces are 0.70, 0.50, and 0.40, respectively.

Analysis We consider the top surface to be surface 1, the bottom surface to be surface 2, and the side surface to be surface 3. This system is a three-surface enclosure. The view factor from surface 1 to surface 2 is determined from



$$\left.\begin{array}{l}\dfrac{L}{r}=\dfrac{1.2}{0.6}=2\\[2ex] \dfrac{r}{L}=\dfrac{0.6}{1.2}=0.5\end{array}\right\}F_{12}=0.17 \qquad \text{(Fig. 12-7)}$$

The surface areas are

$$A_1 = A_2 = \pi D^2/4 = \pi(1.2\,\text{m})^2/4 = 1.131\,\text{m}^2$$

$$A_3 = \pi DL = \pi(1.2\,\text{m})(1.2\,\text{m}) = 4.524\,\text{m}^2$$

Then other view factors are determined to be

$$F_{12} = F_{21} = 0.17$$

$$F_{11}+F_{12}+F_{13}=1 \longrightarrow 0+0.17+F_{13}=1 \longrightarrow F_{13}=0.83 \quad \text{(summation rule)}, \quad F_{23}=F_{13}=0.83$$

$$A_1F_{13}=A_3F_{31} \longrightarrow (1.131)(0.83)=(4.524)F_{31} \longrightarrow F_{31}=0.21 \quad \text{(reciprocity rule)}, \qquad F_{32}=F_{31}=0.21$$

We now apply Eq. 12-35 to each surface

Surface 1:

$$\sigma T_1^{\,4} = J_1 + \frac{1-\varepsilon_1}{\varepsilon_1}\left[F_{12}(J_1-J_2)+F_{13}(J_1-J_3)\right]$$

$$(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)(500\ \text{K})^4 = J_1 + \frac{1-0.70}{0.70}\left[0.17(J_1-J_2)+0.83(J_1-J_3)\right]$$

Surface 2:

$$\sigma T_2^{\,4} = J_2 + \frac{1-\varepsilon_2}{\varepsilon_2}\left[F_{21}(J_2-J_1)+F_{23}(J_2-J_3)\right]$$

$$(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)(500\ \text{K})^4 = J_2 + \frac{1-0.50}{0.50}\left[0.17(J_2-J_1)+0.83(J_2-J_3)\right]$$

Surface 3:

$$\sigma T_3^{\,4} = J_3 + \frac{1-\varepsilon_3}{\varepsilon_3}\left[F_{31}(J_3-J_1)+F_{32}(J_3-J_2)\right]$$

$$(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)T_3^{\,4} = J_3 + \frac{1-0.40}{0.40}\left[0.21(J_1-J_2)+0.21(J_1-J_3)\right]$$

We now apply Eq. 12-34 to surface 2

$$\dot{Q}_2 = A_2\left[F_{21}(J_2-J_1)+F_{23}(J_2-J_3)\right] = (1.131\,\text{m}^2)\left[0.17(J_2-J_1)+0.83(J_2-J_3)\right]$$

Solving the above four equations, we find

$$T_3 = \mathbf{631\,K},\quad J_1 = 4974\,\text{W/m}^2,\quad J_2 = 8883\,\text{W/m}^2,\quad J_3 = 8193\,\text{W/m}^2$$

The rate of heat transfer between the bottom and the top surface is

$$\dot{Q}_{21} = A_2F_{21}(J_2-J_1) = (1.131\,\text{m}^2)(0.17)(8883-4974)\text{W/m}^2 = \mathbf{751.6\ W}$$

The rate of heat transfer between the bottom and the side surface is

$$\dot{Q}_{23} = A_2F_{23}(J_2-J_3) = (1.131\,\text{m}^2)(0.83)(8883-8197)\text{W/m}^2 = \mathbf{644.0\ W}$$

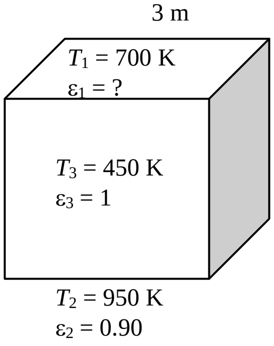
Discussion The sum of these two heat transfer rates are 751.6 + 644 = 1395.6 W, which is practically equal to 1400 W heat supply rate from surface 2. This must be satisfied to maintain the surfaces at the specified temperatures under steady operation. Note that the difference is due to round-off error.

12-99 A cylindrical furnace with specified top and bottom surface temperatures and specified heat transfer rate at the bottom surface is considered. The emissivity of the top surface and the net rates of heat transfer between the top and the bottom surfaces, and between the bottom and the side surfaces are to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivity of the bottom surface is 0.90.

Analysis We consider the top surface to be surface 1, the base surface to be surface 2, and the side surface to be surface 3. This system is a three-surface enclosure. The view factor from the base to the top surface of the cube is $F_{12} = 0.2$. The view factor from the base or the top to the side surfaces is determined by applying the summation rule to be



$$F_{11} + F_{12} + F_{13} = 1 \longrightarrow F_{13} = 1 - F_{12} = 1 - 0.2 = 0.8$$

since the base surface is flat and thus $F_{11} = 0$. Other view factors are

$$F_{21} = F_{12} = 0.20, \qquad F_{23} = F_{13} = 0.80, \qquad F_{31} = F_{32} = 0.20$$

We now apply Eq. 9-35 to each surface

Surface 1:
$$\sigma T_1^4 = J_1 + \frac{1-\varepsilon_1}{\varepsilon_1}\left[F_{12}(J_1 - J_2) + F_{13}(J_1 - J_3)\right]$$
$$(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)(700\ \text{K})^4 = J_1 + \frac{1-\varepsilon_1}{\varepsilon_1}\left[0.20(J_1 - J_2) + 0.80(J_1 - J_3)\right]$$

Surface 2:
$$\sigma T_2^4 = J_2 + \frac{1-\varepsilon_2}{\varepsilon_2}\left[F_{21}(J_2 - J_1) + F_{23}(J_2 - J_3)\right]$$
$$(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)(950\ \text{K})^4 = J_2 + \frac{1-0.90}{0.90}\left[0.20(J_2 - J_1) + 0.80(J_2 - J_3)\right]$$

Surface 3:
$$\sigma T_3^4 = J_3$$
$$(5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4)(450\ \text{K})^4 = J_3$$

We now apply Eq. 9-34 to surface 2

$$\dot{Q}_2 = A_2\left[F_{21}(J_2 - J_1) + F_{23}(J_2 - J_3)\right] = (9\ \text{m}^2)\left[0.20(J_2 - J_1) + 0.80(J_2 - J_3)\right]$$

Solving the above four equations, we find

$$\varepsilon_1 = \mathbf{0.44}, \quad J_1 = 11{,}736\ \text{W/m}^2, \quad J_2 = 41{,}985\ \text{W/m}^2, \quad J_3 = 2325\ \text{W/m}^2$$

The rate of heat transfer between the bottom and the top surface is

$$A_1 = A_2 = (3\ \text{m})^2 = 9\ \text{m}^2$$

$$\dot{Q}_{21} = A_2 F_{21}(J_2 - J_1) = (9\ \text{m}^2)(0.20)(41{,}985 - 11{,}736)\text{W/m}^2 = \mathbf{54.4\ kW}$$

The rate of heat transfer between the bottom and the side surface is

$$A_3 = 4A_1 = 4(9\ \text{m}^2) = 36\ \text{m}^2$$

$$\dot{Q}_{23} = A_2 F_{23}(J_2 - J_3) = (9\ \text{m}^2)(0.8)(41{,}985 - 2325)\text{W/m}^2 = \mathbf{285.6\ kW}$$

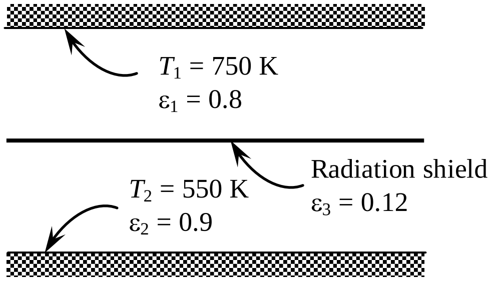
Discussion The sum of these two heat transfer rates are 54.4 + 285.6 = 340 kW, which is equal to 340 kW heat supply rate from surface 2.

12-100 A thin aluminum sheet is placed between two very large parallel plates that are maintained at uniform temperatures. The net rate of radiation heat transfer between the plates and the temperature of the radiation shield are to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivities of surfaces are given to be $\varepsilon_1 = 0.8$, $\varepsilon_2 = 0.9$, and $\varepsilon_3 = 0.12$.

Analysis The net rate of radiation heat transfer with a thin aluminum shield per unit area of the plates is



$$\begin{aligned}\dot{Q}_{12,\text{one shield}} &= \frac{\sigma(T_1^{\,4} - T_2^{\,4})}{\left(\dfrac{1}{\varepsilon_1}+\dfrac{1}{\varepsilon_2}-1\right)+\left(\dfrac{1}{\varepsilon_{3,1}}+\dfrac{1}{\varepsilon_{3,2}}-1\right)} \\ &= \frac{(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(750\ \text{K})^4-(550\ \text{K})^4]}{\left(\dfrac{1}{0.8}+\dfrac{1}{0.9}-1\right)+\left(\dfrac{1}{0.12}+\dfrac{1}{0.12}-1\right)} \\ &= \mathbf{748.9\ W/m^2}\end{aligned}$$

The equilibrium temperature of the radiation shield is determined from

$$\dot{Q}_{13} = \frac{\sigma(T_1^{\,4} - T_3^{\,4})}{\left(\dfrac{1}{\varepsilon_1}+\dfrac{1}{\varepsilon_3}-1\right)}$$

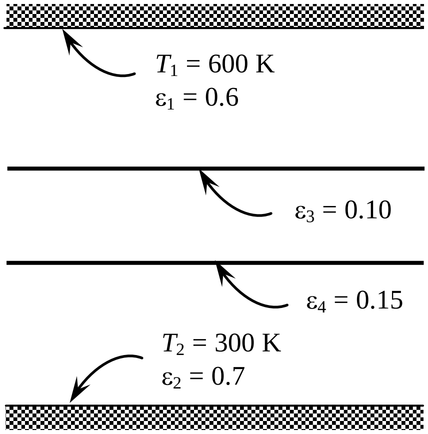
$$748.9\ \text{W/m}^2 = \frac{(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(750\ \text{K})^4 - T_3^{\,4}]}{\left(\dfrac{1}{0.8}+\dfrac{1}{0.12}-1\right)} \longrightarrow T_3 = \mathbf{671.3\ K}$$

12-101 Two thin radiation shields are placed between two large parallel plates that are maintained at uniform temperatures. The net rate of radiation heat transfer between the plates with and without the shields, and the temperatures of radiation shields are to be determined.

Assumptions **1** Steady operating conditions exist **2** The surfaces are opaque, diffuse, and gray. **3** Convection heat transfer is not considered.

Properties The emissivities of surfaces are given to be $\varepsilon_1 = 0.6$, $\varepsilon_2 = 0.7$, $\varepsilon_3 = 0.10$, and $\varepsilon_4 = 0.15$.

Analysis The net rate of radiation heat transfer without the shields per unit area of the plates is



$$\dot{Q}_{12,\text{no shield}} = \frac{\sigma(T_1^{\,4} - T_2^{\,4})}{\dfrac{1}{\varepsilon_1} + \dfrac{1}{\varepsilon_2} - 1} = \frac{(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(600\ \text{K})^4 - (300\ \text{K})^4]}{\dfrac{1}{0.6} + \dfrac{1}{0.7} - 1} = \mathbf{3288\ W/m^2}$$

The net rate of radiation heat transfer with two thin radiation shields per unit area of the plates is

$$\dot{Q}_{12,\text{two-shields}} = \frac{\sigma(T_1^{\,4} - T_2^{\,4})}{\left(\dfrac{1}{\varepsilon_1} + \dfrac{1}{\varepsilon_2} - 1\right) + \left(\dfrac{1}{\varepsilon_3} + \dfrac{1}{\varepsilon_3} - 1\right) + \left(\dfrac{1}{\varepsilon_4} + \dfrac{1}{\varepsilon_4} - 1\right)}$$

$$= \frac{(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(600\ \text{K})^4 - (300\ \text{K})^4]}{\left(\dfrac{1}{0.6} + \dfrac{1}{0.7} - 1\right) + \left(\dfrac{1}{0.10} + \dfrac{1}{0.10} - 1\right) + \left(\dfrac{1}{0.15} + \dfrac{1}{0.15} - 1\right)} = \mathbf{206\ W/m^2}$$

The equilibrium temperatures of the radiation shields are determined from

$$\dot{Q}_{13} = \frac{\sigma(T_1^{\,4} - T_3^{\,4})}{\left(\dfrac{1}{\varepsilon_1} + \dfrac{1}{\varepsilon_3} - 1\right)}$$

$$206\ \text{W/m}^2 = \frac{(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(600\ \text{K})^4 - T_3^{\,4}]}{\left(\dfrac{1}{0.6} + \dfrac{1}{0.10} - 1\right)} \longrightarrow T_3 = \mathbf{549\ K}$$

$$\dot{Q}_{42} = \frac{\sigma(T_4^{\,4} - T_2^{\,4})}{\left(\dfrac{1}{\varepsilon_4} + \dfrac{1}{\varepsilon_2} - 1\right)}$$

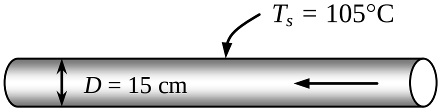
$$206\ \text{W/m}^2 = \frac{(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[T_4^{\,4} - (300\ \text{K})^4]}{\left(\dfrac{1}{0.15} + \dfrac{1}{0.7} - 1\right)} \longrightarrow T_4 = \mathbf{429\ K}$$

12-102 Combustion gases flow inside a tube in a boiler. The rates of heat transfer by convection and radiation and the rate of evaporation of water are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The inner surfaces of the duct are smooth. **3** Combustion gases are assumed to have the properties of air, which is an ideal gas with constant properties.

Properties The properties of air at 1200 K = 927°C and 1 atm are (Table A-15)

$$\rho = 0.2944 \text{ kg/m}^3 \qquad C_p = 1173 \text{ J/kg.°C}$$
$$k = 0.07574 \text{ W/m.°C} \qquad \text{Pr} = 0.7221$$
$$\upsilon = 1.586\times10^{-5} \text{ m}^2\text{/s}$$



Combustion gases, 1 atm
T_i = 1200 K
3 m/s

Analysis (*a*) The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_m D}{\upsilon} = \frac{(3 \text{ m/s})(0.15 \text{ m})}{1.586\times10^{-5} \text{ m}^2\text{/s}} = 28{,}373$$

which is greater than 10,000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D = 10(0.15 \text{ m}) = 1.5 \text{ m}$$

which is much shorter than the total length of the duct. Therefore, we can assume fully developed turbulent flow in the entire duct, and determine the Nusselt number from

$$Nu = \frac{hD_h}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.3} = 0.023(28{,}373)^{0.8}(0.7221)^{0.3} = 76.14$$

Heat transfer coefficient is

$$h = \frac{k}{D} Nu = \frac{0.07574 \text{ W/m.°C}}{0.15 \text{ m}}(76.14) = 38.45 \text{ W/m}^2\text{.°C}$$

Next we determine the exit temperature of air

$$A = \pi DL = \pi(0.15 \text{ m})(6 \text{ m}) = 2.827 \text{ m}^2$$
$$A_c = \pi D^2/4 = \pi(0.15 \text{ m})^2/4 = 0.01767 \text{ m}^2$$
$$\dot{m} = \rho V A_c = (0.2944 \text{ kg/m}^3)(3 \text{ m/s})(0.01767 \text{ m}^2) = 0.01561 \text{ kg/s}$$

$$T_e = T_s - (T_s - T_i)e^{-hA/(\dot{m}C_p)} = 105 - (105 - 927)e^{-\frac{(38.45)(2.827)}{(0.01561)(1173)}} = 107.2\text{°C}$$

Then the rate of heat transfer by convection becomes

$$\dot{Q}_{\text{conv}} = \dot{m}C_p(T_i - T_e) = (0.01561 \text{ kg/s})(1173 \text{ J/kg.°C})(927 - 107.2)\text{°C} = \mathbf{15{,}010\ W}$$

Next, we determine the emissivity of combustion gases. First, the mean beam length for an infinite circular cylinder is, from Table 12-4,

$$L = 0.95(0.15 \text{ m}) = 0.1425 \text{ m}$$

Then,

$$P_c L = (0.08 \text{ atm})(0.1425 \text{ m}) = 0.0114 \text{ m}\cdot\text{atm} = 0.037 \text{ ft}\cdot\text{atm}$$
$$P_w L = (0.16 \text{ atm})(0.1425 \text{ m}) = 0.0228 \text{ m}\cdot\text{atm} = 0.075 \text{ ft}\cdot\text{atm}$$

The emissivities of CO_2 and H_2O corresponding to these values at the average gas temperature of T_g=(T_g+T_g)/2 = (927+107.2)/2 = 517.1°C = 790 K and 1atm are, from Fig. 12-36,

$$\varepsilon_{c,1\text{atm}} = 0.055 \quad \text{and} \quad \varepsilon_{w,1\text{atm}} = 0.062$$

Both CO_2 and H_2O are present in the same mixture, and we need to correct for the overlap of emission bands. The emissivity correction factor at $T = T_g = 800$ K is, from Fig. 12-38,

$$\left.\begin{aligned} P_cL + P_wL &= 0.037 + 0.075 = 0.112 \\ \frac{P_w}{P_w + P_c} &= \frac{0.16}{0.16 + 0.08} = 0.67 \end{aligned}\right\} \Delta\varepsilon = 0.0$$

Then the effective emissivity of the combustion gases becomes

$$\varepsilon_g = C_c\varepsilon_{c,1\,\text{atm}} + C_w\varepsilon_{w,1\,\text{atm}} - \Delta\varepsilon = 1\times 0.055 + 1\times 0.062 - 0.0 = 0.117$$

Note that the pressure correction factor is 1 for both gases since the total pressure is 1 atm. For a source temperature of T_s = 105°C = 378 K, the absorptivity of the gas is again determined using the emissivity charts as follows:

$$P_cL\frac{T_s}{T_g} = (0.08\text{ atm})(0.1425\text{ m})\frac{378\text{ K}}{790\text{ K}} = 0.00545\text{ m}\cdot\text{atm} = 0.018\text{ ft}\cdot\text{atm}$$

$$P_wL\frac{T_s}{T_g} = (0.16\text{ atm})(0.1425\text{ m})\frac{378\text{ K}}{790\text{ K}} = 0.0109\text{ m}\cdot\text{atm} = 0.036\text{ ft}\cdot\text{atm}$$

The emissivities of CO_2 and H_2O corresponding to these values at a temperature of T_s = 378 K and 1atm are, from Fig. 12-36,

$$\varepsilon_{c,1\,\text{atm}} = 0.037 \quad\text{and}\quad \varepsilon_{w,1\,\text{atm}} = 0.062$$

Then the absorptivities of CO_2 and H_2O become

$$\alpha_c = C_c\left(\frac{T_g}{T_s}\right)^{0.65}\varepsilon_{c,1\,\text{atm}} = (1)\left(\frac{790\text{ K}}{378\text{ K}}\right)^{0.65}(0.037) = 0.0597$$

$$\alpha_w = C_w\left(\frac{T_g}{T_s}\right)^{0.45}\varepsilon_{w,1\,\text{atm}} = (1)\left(\frac{790\text{ K}}{378\text{ K}}\right)^{0.45}(0.062) = 0.0864$$

Also $\Delta\alpha = \Delta\varepsilon$, but the emissivity correction factor is to be evaluated from Fig. 12-38 at $T = T_s$ = 378 K instead of T_g = 790 K. We use the chart for 400 K. At $P_w/(P_w + P_c) = 0.67$ and $P_cL + P_wL = 0.112$ we read $\Delta\varepsilon = 0.0$. Then the absorptivity of the combustion gases becomes

$$\alpha_g = \alpha_c + \alpha_w - \Delta\alpha = 0.0597 + 0.0864 - 0.0 = 0.146$$

The emissivity of the inner surface s of the tubes is 0.9. Then the net rate of radiation heat transfer from the combustion gases to the walls of the tube becomes

$$\begin{aligned} \dot{Q}_{\text{rad}} &= \frac{\varepsilon_s + 1}{2}A_s\sigma(\varepsilon_g T_g^4 - \alpha_g T_s^4) \\ &= \frac{0.9 + 1}{2}(2.827\text{ m}^2)(5.67\times 10^{-8}\text{ W/m}^2\cdot\text{K}^4)[0.117(790\text{ K})^4 - 0.146(378\text{ K})^4] \\ &= \mathbf{6486\ W} \end{aligned}$$

(*b*) The heat of vaporization of water at 1 atm is 2257 kJ/kg (Table A-9). Then rate of evaporation of water becomes

$$\dot{Q}_{\text{conv}} + \dot{Q}_{\text{rad}} = \dot{m}_{\text{evap}}h_{fg} \longrightarrow \dot{m}_{\text{evap}} = \frac{\dot{Q}_{\text{conv}} + \dot{Q}_{\text{rad}}}{h_{fg}} = \frac{(15{,}010 + 6486)\text{ W}}{333.7\times 10^3\text{ J/kg}} = \mathbf{0.0644\ kg/s}$$

12-103 Combustion gases flow inside a tube in a boiler. The rates of heat transfer by convection and radiation and the rate of evaporation of water are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The inner surfaces of the duct are smooth. **3** Combustion gases are assumed to have the properties of air, which is an ideal gas with constant properties.

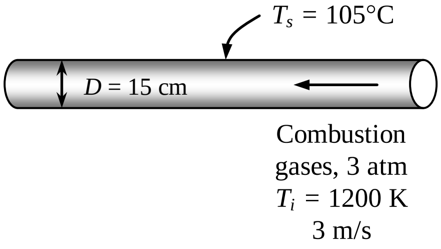
Properties The properties of air at 1200 K = 927°C and 3 atm are (Table A-15)

$$\rho = 0.2944\ \text{kg/m}^3 \qquad C_p = 1173\ \text{J/kg.°C}$$

$$k = 0.07574\ \text{W/m.°C} \qquad \text{Pr} = 0.7221$$

$$\upsilon = (1.586\times10^{-5}\ \text{m}^2/\text{s})/3$$

$$= 0.5287\times10^{-5}\ \text{m}^2/\text{s}$$



Analysis (*a*) The Reynolds number is

$$\text{Re} = \frac{\mathbf{V}_m D}{\upsilon} = \frac{(3\ \text{m/s})(0.15\ \text{m})}{0.5287\times10^{-5}\ \text{m}^2/\text{s}} = 85{,}114$$

which is greater than 10,000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D = 10(0.15\ \text{m}) = 1.5\ \text{m}$$

which is much shorter than the total length of the duct. Therefore, we can assume fully developed turbulent flow in the entire duct, and determine the Nusselt number from

$$Nu = \frac{hD_h}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.3} = 0.023(85{,}114)^{0.8}(0.7221)^{0.3} = 183.4$$

Heat transfer coefficient is

$$h = \frac{k}{D}Nu = \frac{0.07574\ \text{W/m.°C}}{0.15\ \text{m}}(183.4) = 92.59\ \text{W/m}^2.\text{°C}$$

Next we determine the exit temperature of air

$$A = \pi DL = \pi(0.15\ \text{m})(6\ \text{m}) = 2.827\ \text{m}^2$$

$$A_c = \pi D^2/4 = \pi(0.15\ \text{m})^2/4 = 0.01767\ \text{m}^2$$

$$\dot m = \rho V A_c = (0.2944\ \text{kg/m}^3)(3\ \text{m/s})(0.01767\ \text{m}^2) = 0.01561\ \text{kg/s}$$

$$T_e = T_s - (T_s - T_i)e^{-hA/(\dot m C_p)} = 105 - (105 - 927)e^{-\frac{(92.59)(2.827)}{(0.01561)(1173)}} = 105.0\text{°C}$$

Then the rate of heat transfer by convection becomes

$$\dot Q_\text{conv} = \dot m C_p(T_i - T_e) = (0.01561\ \text{kg/s})(1173\ \text{J/kg.°C})(927 - 105.0)\text{°C} = \mathbf{15{,}050\ W}$$

Next, we determine the emissivity of combustion gases. First, the mean beam length for an infinite circular cylinder is, from Table 12-4,

$$L = 0.95(0.15\ \text{m}) = 0.1425\ \text{m}$$

Then,

$$P_c L = (0.08\ \text{atm})(0.1425\ \text{m}) = 0.0114\ \text{m}\cdot\text{atm} = 0.037\ \text{ft}\cdot\text{atm}$$

$$P_w L = (0.16\ \text{atm})(0.1425\ \text{m}) = 0.0228\ \text{m}\cdot\text{atm} = 0.075\ \text{ft}\cdot\text{atm}$$

The emissivities of CO_2 and H_2O corresponding to these values at the average gas temperature of T_g=(T_g+T_g)/2 = (927+105)/2 = 516°C = 790 K and 1atm are, from Fig. 12-36,

$$\varepsilon_{c,1\,\text{atm}} = 0.055 \quad \text{and} \quad \varepsilon_{w,1\,\text{atm}} = 0.062$$

These are the base emissivity values at 1 atm, and they need to be corrected for the 3 atm total pressure. Noting that (P_w+P)/2 = (0.16+3)/2 = 1.58 atm, the pressure correction factors are, from Fig. 12-37,

$$C_c = 1.5 \quad \text{and} \quad C_w = 1.8$$

Both CO_2 and H_2O are present in the same mixture, and we need to correct for the overlap of emission bands. The emissivity correction factor at T = T_g = 800 K is, from Fig. 12-38,

$$\left.\begin{aligned} &P_c L + P_w L = 0.037 + 0.075 = 0.112 \\ &\frac{P_w}{P_w + P_c} = \frac{0.16}{0.16 + 0.08} = 0.67 \end{aligned}\right\} \Delta\varepsilon = 0.0$$

Then the effective emissivity of the combustion gases becomes

$$\varepsilon_g = C_c \varepsilon_{c,1\,\text{atm}} + C_w \varepsilon_{w,1\,\text{atm}} - \Delta\varepsilon = 1.5\times 0.055 + 1.8\times 0.062 - 0.0 = 0.194$$

For a source temperature of T_s = 105°C = 378 K, the absorptivity of the gas is again determined using the emissivity charts as follows:

$$P_c L \frac{T_s}{T_g} = (0.08\,\text{atm})(0.1425\,\text{m})\frac{378\,\text{K}}{790\,\text{K}} = 0.00545\,\text{m}\cdot\text{atm} = 0.018\,\text{ft}\cdot\text{atm}$$

$$P_w L \frac{T_s}{T_g} = (0.16\,\text{atm})(0.1425\,\text{m})\frac{378\,\text{K}}{790\,\text{K}} = 0.0109\,\text{m}\cdot\text{atm} = 0.036\,\text{ft}\cdot\text{atm}$$

The emissivities of CO_2 and H_2O corresponding to these values at a temperature of T_s = 378 K and 1atm are, from Fig. 12-36,

$$\varepsilon_{c,1\,\text{atm}} = 0.037 \quad \text{and} \quad \varepsilon_{w,1\,\text{atm}} = 0.062$$

Then the absorptivities of CO_2 and H_2O become

$$\alpha_c = C_c\left(\frac{T_g}{T_s}\right)^{0.65} \varepsilon_{c,1\,\text{atm}} = (1.5)\left(\frac{790\,\text{K}}{378\,\text{K}}\right)^{0.65}(0.037) = 0.0896$$

$$\alpha_w = C_w\left(\frac{T_g}{T_s}\right)^{0.45} \varepsilon_{w,1\,\text{atm}} = (1.8)\left(\frac{790\,\text{K}}{378\,\text{K}}\right)^{0.45}(0.062) = 0.1555$$

Also $\Delta\alpha = \Delta\varepsilon$, but the emissivity correction factor is to be evaluated from Fig. 12-38 at $T = T_s$ = 378 K instead of T_g = 790 K. We use the chart for 400 K. At $P_w/(P_w + P_c) = 0.67$ and $P_c L + P_w L = 0.112$ we read $\Delta\varepsilon = 0.0$. Then the absorptivity of the combustion gases becomes

$$\alpha_g = \alpha_c + \alpha_w - \Delta\alpha = 0.0896 + 0.1555 - 0.0 = 0.245$$

The emissivity of the inner surfaces of the tubes is 0.9. Then the net rate of radiation heat transfer from the combustion gases to the walls of the tube becomes

$$\begin{aligned} \dot{Q}_\text{rad} &= \frac{\varepsilon_s + 1}{2} A_s \sigma(\varepsilon_g T_g^4 - \alpha_g T_s^4) \\ &= \frac{0.9 + 1}{2}(2.827\,\text{m}^2)(5.67\times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4)[0.194(790\,\text{K})^4 - 0.245(378\,\text{K})^4] \\ &= \mathbf{10{,}745\ W} \end{aligned}$$

(*b*) The heat of vaporization of water at 1 atm is 2257 kJ/kg (Table A-9). Then rate of evaporation of water becomes

$$\dot{Q}_\text{conv} + \dot{Q}_\text{rad} = \dot{m}_\text{evap} h_{fg} \longrightarrow \dot{m}_\text{evap} = \frac{\dot{Q}_\text{conv} + \dot{Q}_\text{rad}}{h_{fg}} = \frac{(15{,}050 + 10{,}745)\,\text{W}}{333.7\times 10^3\,\text{J/kg}} = \mathbf{0.0773\ kg/s}$$

12-104 ….. 12-106 Design and Essay Problems

⁂

Chapter 13

HEAT EXCHANGERS

Types of Heat Exchangers

13-1C Heat exchangers are classified according to the flow type as parallel flow, counter flow, and cross-flow arrangement. In parallel flow, both the hot and cold fluids enter the heat exchanger at the same end and move in the same direction. In counter-flow, the hot and cold fluids enter the heat exchanger at opposite ends and flow in opposite direction. In cross-flow, the hot and cold fluid streams move perpendicular to each other.

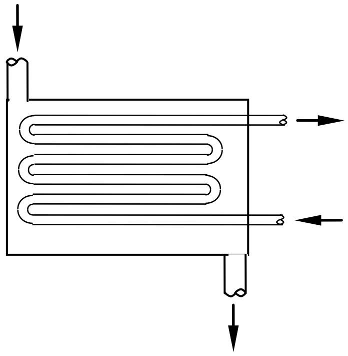
13-2C In terms of construction type, heat exchangers are classified as compact, shell and tube and regenerative heat exchangers. Compact heat exchangers are specifically designed to obtain large heat transfer surface areas per unit volume. The large surface area in compact heat exchangers is obtained by attaching closely spaced thin plate or corrugated fins to the walls separating the two fluids. Shell and tube heat exchangers contain a large number of tubes packed in a shell with their axes parallel to that of the shell. Regenerative heat exchangers involve the alternate passage of the hot and cold fluid streams through the same flow area. In compact heat exchangers, the two fluids usually move perpendicular to each other.

13-3C A heat exchanger is classified as being compact if $\beta > 700\ \text{m}^2/\text{m}^3$ or ($200\ \text{ft}^2/\text{ft}^3$) where β is the ratio of the heat transfer surface area to its volume which is called the area density. The area density for double-pipe heat exchanger can not be in the order of 700. Therefore, it can not be classified as a compact heat exchanger.

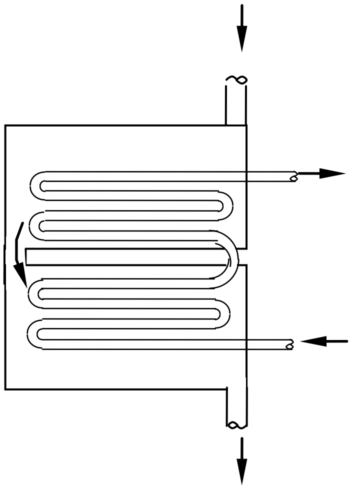
13-4C In counter-flow heat exchangers, the hot and the cold fluids move parallel to each other but both enter the heat exchanger at opposite ends and flow in opposite direction. In cross-flow heat exchangers, the two fluids usually move perpendicular to each other. The cross-flow is said to be unmixed when the plate fins force the fluid to flow through a particular interfin spacing and prevent it from moving in the transverse direction. When the fluid is free to move in the transverse direction, the cross-flow is said to be mixed.

13-5C In the shell and tube exchangers, baffles are commonly placed in the shell to force the shell side fluid to flow across the shell to enhance heat transfer and to maintain uniform spacing between the tubes. Baffles disrupt the flow of fluid, and an increased pumping power will be needed to maintain flow. On the other hand, baffles eliminate dead spots and increase heat transfer rate.

13-6C Using six-tube passes in a shell and tube heat exchanger increases the heat transfer surface area, and the rate of heat transfer increases. But it also increases the manufacturing costs.



13-7C Using so many tubes increases the heat transfer surface area which in turn increases the rate of heat transfer.



13-8C Regenerative heat exchanger involves the alternate passage of the hot and cold fluid streams through the same flow area. The static type regenerative heat exchanger is basically a porous mass which has a large heat storage capacity, such as a ceramic wire mash. Hot and cold fluids flow through this porous mass alternately. Heat is transferred from the hot fluid to the matrix of the regenerator during the flow of the hot fluid and from the matrix to the cold fluid. Thus the matrix serves as a temporary heat storage medium. The dynamic type regenerator involves a rotating drum and continuous flow of the hot and cold fluid through different portions of the drum so that any portion of the drum passes periodically through the hot stream, storing heat and then through the cold stream, rejecting this stored heat. Again the drum serves as the medium to transport the heat from the hot to the cold fluid stream.

The Overall Heat Transfer Coefficient

13-9C Heat is first transferred from the hot fluid to the wall by convection, through the wall by conduction and from the wall to the cold fluid again by convection.

13-10C When the wall thickness of the tube is small and the thermal conductivity of the tube material is high, which is usually the case, the thermal resistance of the tube is negligible.

13-11C The heat transfer surface areas are $A_i = \pi D_1 L$ and $A_o = \pi D_2 L$. When the thickness of inner tube is small, it is reasonable to assume $A_i \cong A_o \cong A_s$.

13-12C No, it is not reasonable to say $h_i \approx h_0 \approx h$

13-13C When the wall thickness of the tube is small and the thermal conductivity of the tube material is high, the thermal resistance of the tube is negligible and the inner and the outer surfaces of the tube are almost identical ($A_i \cong A_o \cong A_s$). Then the overall heat transfer coefficient of a heat exchanger can be determined to from $U = (1/h_i + 1/h_o)^{-1}$

13-14C None.

13-15C When one of the convection coefficients is much smaller than the other $h_i << h_o$, and $A_i \approx A_0 \approx A_s$. Then we have ($1/h_i >> 1/h_o$) and thus $U_i = U_0 = U \cong h_i$.

13-16C The most common type of fouling is the precipitation of solid deposits in a fluid on the heat transfer surfaces. Another form of fouling is corrosion and other chemical fouling. Heat exchangers may also be fouled by the growth of algae in warm fluids. This type of fouling is called the biological fouling. Fouling represents additional resistance to heat transfer and causes the rate of heat transfer in a heat exchanger to decrease, and the pressure drop to increase.

13-17C The effect of fouling on a heat transfer is represented by a fouling factor R_f. Its effect on the heat transfer coefficient is accounted for by introducing a thermal resistance R_f/A_s. The fouling increases with increasing temperature and decreasing velocity.

13-18 The heat transfer coefficients and the fouling factors on tube and shell side of a heat exchanger are given. The thermal resistance and the overall heat transfer coefficients based on the inner and outer areas are to be determined.

Assumptions **1** The heat transfer coefficients and the fouling factors are constant and uniform.

Analysis (*a*) The total thermal resistance of the heat exchanger per unit length is

$$R = \frac{1}{h_i A_i} + \frac{R_{fi}}{A_i} + \frac{\ln(D_o / D_i)}{2\pi kL} + \frac{R_{fo}}{A_o} + \frac{1}{h_o A_o}$$

$$R = \frac{1}{(700\ \text{W/m}^2.°\text{C})[\pi(0.012\ \text{m})(1\ \text{m})]} + \frac{(0.0005\ \text{m}^2.°\text{C/W})}{[\pi(0.012\ \text{m})(1\ \text{m})]}$$

$$+ \frac{\ln(1.6/1.2)}{2\pi(380\ \text{W/m}.°\text{C})(1\ \text{m})} + \frac{(0.0002\ \text{m}^2.°\text{C/W})}{[\pi(0.016\ \text{m})(1\ \text{m})]}$$

$$+ \frac{1}{(700\ \text{W/m}^2.°\text{C})[\pi(0.016\ \text{m})(1\ \text{m})]}$$

$$= \mathbf{0.0837°C/W}$$

Inner surface
D_i, A_i, h_i, U_i , R_{fi}

(*b*) The overall heat transfer coefficient based on the inner and the outer surface areas of the tube per length are

$$R = \frac{1}{UA} = \frac{1}{U_i A_i} = \frac{1}{U_o A_o}$$

$$U_i = \frac{1}{RA_i} = \frac{1}{(0.0837\ °\text{C/W})[\pi(0.012\ \text{m})(1\ \text{m})]} = \mathbf{317\ W/m^2.°C}$$

$$U_o = \frac{1}{RA_o} = \frac{1}{(0.0837\ °\text{C/W})[\pi(0.016\ \text{m})(1\ \text{m})]} = \mathbf{238\ W/m^2.°C}$$

D_i, A_i, h_i, U_i , R_{fi}

Analysis The Reynolds number is

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(3.5\ \text{m/s})(0.01\ \text{m})}{0.268\times10^{-6}\ \text{m}^2/\text{s}} = 130{,}600$$

which is greater than 10,000. Therefore, the flow is turbulent. Assuming fully developed flow,

$$Nu = \frac{hD_h}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.4} = 0.023(130{,}600)^{0.8}(1.58)^{0.4} = 342$$

and $$h = \frac{k}{D_h}Nu = \frac{0.682\ \text{W/m.°C}}{0.01\ \text{m}}(342) = 23{,}324\ \text{W/m}^2.\text{°C}$$

The total resistance of this heat exchanger is then determined from

$$R = R_{total} = R_i + R_{wall} + R_o = \frac{1}{h_i A_i} + \frac{\ln(D_o/D_i)}{2\pi kL} + \frac{1}{h_o A_o}$$
$$= \frac{1}{(23{,}324\ \text{W/m}^2.\text{°C})[\pi(0.01\ \text{m})(5\ \text{m})]} + \frac{\ln(1.4/1)}{[2\pi(14.2\ \text{W/m.°C})(5\ \text{m})]}$$
$$+ \frac{1}{(8400\ \text{W/m}^2.\text{°C})[\pi(0.014\ \text{m})(5\ \text{m})]}$$
$$= 0.00157\text{°C/W}$$

and $$R = \frac{1}{U_i A_i} \longrightarrow U_i = \frac{1}{RA_i} = \frac{1}{(0.00157\text{°C/W})[\pi(0.01\ \text{m})(5\ \text{m})]} = \mathbf{4055\ W/m^2.°C}$$

13-21 Water is flowing through the tubes in a boiler. The overall heat transfer coefficient of this boiler based on the inner surface area is to be determined.

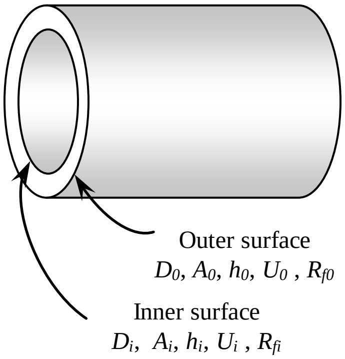
Assumptions **1** Water flow is fully developed. **2** Properties of water are constant. **3** The heat transfer coefficient and the fouling factor are constant and uniform.

Properties The properties water at 107°C ≈ 110°C are (Table A-9)

$$\upsilon = \mu / \rho = 0.268 \times 10^{-6}\ \text{m}^2/\text{s}$$

$$k = 0.682\ \text{W/m}^2.\text{K}$$

$$\text{Pr} = 1.58$$



Outer surface
D_0, A_0, h_0, U_0 , R_{f0}
Inner surface
D_i, A_i, h_i, U_i , R_{fi}

Analysis The Reynolds number is

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(3.5\ \text{m/s})(0.01\ \text{m})}{0.268 \times 10^{-6}\ \text{m}^2/\text{s}} = 130{,}600$$

which is greater than 10,000. Therefore, the flow is turbulent. Assuming fully developed flow,

$$Nu = \frac{hD_h}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.4} = 0.023(130{,}600)^{0.8}(1.58)^{0.4} = 342$$

and $$h = \frac{k}{D_h} Nu = \frac{0.682\ \text{W/m.°C}}{0.01\ \text{m}}(342) = 23{,}324\ \text{W/m}^2.\text{°C}$$

The thermal resistance of heat exchanger with a fouling factor of $R_{f,i} = 0.0005\ \text{m}^2.\text{°C/W}$ is determined from

$$R = \frac{1}{h_i A_i} + \frac{R_{f,i}}{A_i} + \frac{\ln(D_o / D_i)}{2\pi kL} + \frac{1}{h_o A_o}$$

$$R = \frac{1}{(23{,}324\ \text{W/m}^2.\text{°C})[\pi(0.01\ \text{m})(5\ \text{m})]} + \frac{0.0005\ \text{m}^2.\text{°C/W}}{[\pi(0.01\ \text{m})(5\ \text{m})]}$$
$$+ \frac{\ln(1.4/1)}{2\pi(14.2\ \text{W/m.°C})(5\ \text{m})} + \frac{1}{(8400\ \text{W/m}^2.\text{°C})[\pi(0.014\ \text{m})(5\ \text{m})]}$$
$$= 0.00476\text{°C/W}$$

Then,

$$R = \frac{1}{U_i A_i} \longrightarrow U_i = \frac{1}{RA_i} = \frac{1}{(0.00476\text{°C/W})[\pi(0.01\ \text{m})(5\ \text{m})]} = \mathbf{1337\ W/m^2.°C}$$

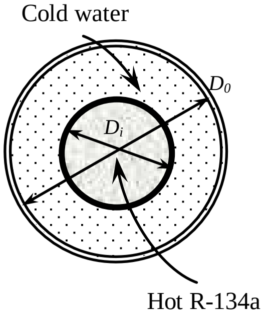
13-23 Refrigerant-134a is cooled by water in a double-pipe heat exchanger. The overall heat transfer coefficient is to be determined.

Assumptions **1** The thermal resistance of the inner tube is negligible since the tube material is highly conductive and its thickness is negligible. **2** Both the water and refrigerant-134a flow are fully developed. **3** Properties of the water and refrigerant-134a are constant.

Properties The properties water at 20°C are (Table A-9)



$$\rho = 998\ \text{kg/m}^3$$
$$\upsilon = \mu/\rho = 1.004\times10^{-6}\ \text{m}^2\text{/s}$$
$$k = 0.598\ \text{W/m.°C}$$
$$\text{Pr} = 7.01$$

Analysis The hydraulic diameter for annular space is

$$D_h = D_o - D_i = 0.025 - 0.01 = 0.015\ \text{m}$$

The average velocity of water in the tube and the Reynolds number are

$$V_m = \frac{\dot m}{\rho A_c} = \frac{\dot m}{\rho\left(\pi\dfrac{D_o^{\,2} - D_i^{\,2}}{4}\right)} = \frac{0.3\ \text{kg/s}}{(998\ \text{kg/m}^3)\left(\pi\dfrac{(0.025\ \text{m})^2 - (0.01\ \text{m})^2}{4}\right)} = 0.729\ \text{m/s}$$

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(0.729\ \text{m/s})(0.015\ \text{m})}{1.004\times10^{-6}\ \text{m}^2/\text{s}} = 10{,}890$$

which is greater than 10,000. Therefore flow is turbulent. Assuming fully developed flow,

$$Nu = \frac{hD_h}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.4} = 0.023(10{,}890)^{0.8}(7.01)^{0.4} = 85.0$$

and

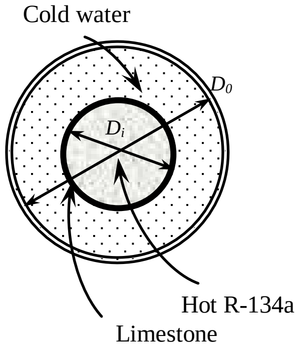
$$h_o = \frac{k}{D_h}Nu = \frac{0.598\ \text{W/m.°C}}{0.015\ \text{m}}(85.0) = 3390\ \text{W/m}^2\text{.°C}$$

Then the overall heat transfer coefficient becomes

$$U = \frac{1}{\dfrac{1}{h_i} + \dfrac{1}{h_o}} = \frac{1}{\dfrac{1}{5000\ \text{W/m}^2\text{.°C}} + \dfrac{1}{3390\ \text{W/m}^2\text{.°C}}} = \mathbf{2020\ W/m^2.°C}$$

13-24 Refrigerant-134a is cooled by water in a double-pipe heat exchanger. The overall heat transfer coefficient is to be determined.

Assumptions **1** The thermal resistance of the inner tube is negligible since the tube material is highly conductive and its thickness is negligible. **2** Both the water and refrigerant-134a flows are fully developed. **3** Properties of the water and refrigerant-134a are constant. **4** The limestone layer can be treated as a plain layer since its thickness is very small relative to its diameter.



Properties The properties water at 20°C are (Table A-9)

$$\rho = 998\ \text{kg/m}^3$$
$$\upsilon = \mu / \rho = 1.004\times10^{-6}\ \text{m}^2\text{/s}$$
$$k = 0.598\ \text{W/m.°C}$$
$$\text{Pr} = 7.01$$

Analysis The hydraulic diameter for annular space is

$$D_h = D_o - D_i = 0.025 - 0.01 = 0.015\ \text{m}$$

The average velocity of water in the tube and the Reynolds number are

$$V_m = \frac{\dot{m}}{\rho A_c} = \frac{\dot{m}}{\rho\left(\pi\dfrac{D_o{}^2 - D_i{}^2}{4}\right)} = \frac{0.3\ \text{kg/s}}{(998\ \text{kg/m}^3)\left(\pi\dfrac{(0.025\ \text{m})^2-(0.01\ \text{m})^2}{4}\right)} = 0.729\ \text{m/s}$$

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(0.729\ \text{m/s})(0.015\ \text{m})}{1.004\times10^{-6}\ \text{m}^2/\text{s}} = 10{,}890$$

which is greater than 10,000. Therefore flow is turbulent. Assuming fully developed flow,

$$Nu = \frac{hD_h}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.4} = 0.023(10{,}890)^{0.8}(7.01)^{0.4} = 85.0$$

and

$$h_o = \frac{k}{D_h}Nu = \frac{0.598\ \text{W/m.°C}}{0.015\ \text{m}}(85.0) = 3390\ \text{W/m}^2\text{.°C}$$

Disregarding the curvature effects, the overall heat transfer coefficient is determined to be

$$U = \frac{1}{\dfrac{1}{h_i}+\left(\dfrac{L}{k}\right)_{\text{limeston}}+\dfrac{1}{h_o}} = \frac{1}{\dfrac{1}{5000\ \text{W/m}^2\text{.°C}}+\dfrac{0.002\ \text{m}}{1.3\ \text{W/m.°C}}+\dfrac{1}{3390\ \text{W/m}^2\text{.°C}}} = \mathbf{493\ W/m^2.°C}$$

13-26E Water is cooled by air in a cross-flow heat exchanger. The overall heat transfer coefficient is to be determined.

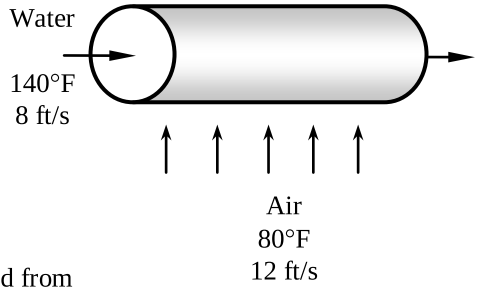
Assumptions **1** The thermal resistance of the inner tube is negligible since the tube material is highly conductive and its thickness is negligible. **2** Both the water and air flow are fully developed. **3** Properties of the water and air are constant.

Properties The properties water at 140°F are (Table A-9E)

$$k = 0.378\ \text{Btu/h.ft.°F}$$
$$\upsilon = 5.11\times10^{-6}\ \text{ft}^2/\text{s}$$
$$\text{Pr} = 2.98$$

The properties of air at 80°F are (Table A-18E)

$$k = 0.0150\ \text{Btu/h.ft.°F}$$
$$\upsilon = 0.17\times10^{-3}\ \text{ft}^2/\text{s}$$
$$\text{Pr} = 0.72$$



Analysis The overall heat transfer coefficient can be determined from

$$\frac{1}{U} = \frac{1}{h_i} + \frac{1}{h_o}$$

The Reynolds number of water is

$$\text{Re} = \frac{V_m D_h}{\upsilon} = \frac{(8\ \text{ft/s})[0.75/12\ \text{ft}]}{5.11\times10^{-6}\ \text{ft}^2/\text{s}} = 97{,}850$$

which is greater than 10,000. Therefore the flow of water is turbulent. Assuming the flow to be fully developed, the Nusselt number is determined from

$$Nu = \frac{hD_h}{k} = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.4} = 0.023(97{,}850)^{0.8}(2.98)^{0.4} = 350$$

and $$h_i = \frac{k}{D_h}Nu = \frac{0.378\ \text{Btu/h.ft.°F}}{0.75/12\ \text{ft}}(350) = 2117\ \text{Btu/h.ft}^2\text{.°F}$$

The Reynolds number of air is

$$\text{Re} = \frac{V_\infty D}{\upsilon} = \frac{(12\ \text{ft/s})[3/(4\times12)\ \text{ft}]}{0.17\times10^{-3}\ \text{ft}^2/\text{s}} = 4412$$

The flow of air is across the cylinder. The proper relation for Nusselt number in this case is

$$Nu = \frac{hD}{k} = 0.3 + \frac{0.62\,\text{Re}^{0.5}\,\text{Pr}^{1/3}}{\left[1+(0.4/\text{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(4412)^{0.5}(0.729)^{1/3}}{\left[1+(0.4/0.729)^{2/3}\right]^{1/4}}\left[1+\left(\frac{4412}{282{,}000}\right)^{5/8}\right]^{4/5} = 34.8$$

and $$h_o = \frac{k}{D}Nu = \frac{0.01481\ \text{Btu/h.ft.°F}}{0.75/12\ \text{ft}}(34.8) = 8.25\ \text{Btu/h.ft}^2\text{.°F}$$

Then the overall heat transfer coefficient becomes

$$U = \frac{1}{\dfrac{1}{h_i}+\dfrac{1}{h_o}} = \frac{1}{\dfrac{1}{2117\ \text{Btu/h.ft}^2\text{.°F}}+\dfrac{1}{8.25\ \text{Btu/h.ft}^2\text{.°F}}} = \mathbf{8.22\ Btu/h.ft^2.°F}$$

Analysis of Heat Exchangers

13-27C The heat exchangers usually operate for long periods of time with no change in their operating conditions, and then they can be modeled as steady-flow devices. As such , the mass flow rate of each fluid remains constant and the fluid properties such as temperature and velocity at any inlet and outlet remain constant. The kinetic and potential energy changes are negligible. The specific heat of a fluid can be treated as constant in a specified temperature range. Axial heat conduction along the tube is negligible. Finally, the outer surface of the heat exchanger is assumed to be perfectly insulated so that there is no heat loss to the surrounding medium and any heat transfer thus occurs is between the two fluids only.

13-28C That relation is valid under steady operating conditions, constant specific heats, and negligible heat loss from the heat exchanger.

13-29C The product of the mass flow rate and the specific heat of a fluid is called the heat capacity rate and is expressed as $C = \dot{m}C_p$. When the heat capacity rates of the cold and hot fluids are equal, the temperature change is the same for the two fluids in a heat exchanger. That is, the temperature rise of the cold fluid is equal to the temperature drop of the hot fluid. A heat capacity of infinity for a fluid in a heat exchanger is experienced during a phase-change process in a condenser or boiler.

13-30C The mass flow rate of the cooling water can be determined from $\dot{Q} = (\dot{m}C_p\Delta T)_{\text{cooling water}}$. The rate of condensation of the steam is determined from $\dot{Q} = (\dot{m}h_{fg})_{\text{steam}}$, and the total thermal resistance of the condenser is determined from $R = \dot{Q} / \Delta T$.

13-31C When the heat capacity rates of the cold and hot fluids are identical, the temperature rise of the cold fluid will be equal to the temperature drop of the hot fluid.

The Log Mean Temperature Difference Method

13-32C ΔT_{lm} is called the log mean temperature difference, and is expressed as

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)}$$

where

$\Delta T_1 = T_{h,in} - T_{c,in}$ $\quad \Delta T_2 = T_{h,out} - T_{c,out}$ for parallel-flow heat exchangers and

$\Delta T = T_{h,in} - T_{c,out}$ $\quad \Delta T_2 = T_{h,out} - T_{c,in}$ for counter-flow heat exchangers

13-33C The temperature difference between the two fluids decreases from ΔT_1 at the inlet to ΔT_2 at the outlet, and arithmetic mean temperature difference is defined as $\Delta T_m = \frac{\Delta T_1 + \Delta T_2}{2}$. The logarithmic mean temperature difference ΔT_{lm} is obtained by tracing the actual temperature profile of the fluids along the heat exchanger, and is an exact representation of the average temperature difference between the hot and cold fluids. It truly reflects the exponential decay of the local temperature difference. The logarithmic mean temperature difference is always less than the arithmetic mean temperature.

13-34C ΔT_{lm} cannot be greater than both ΔT_1 and ΔT_2 because ΔT_{ln} is always less than or equal to ΔT_{m} (arithmetic mean) which can not be greater than both ΔT_1 and ΔT_2.

13-35C No, it cannot. When ΔT_1 is less than ΔT_2 the ratio of them must be less than one and the natural logarithms of the numbers which are less than 1 are negative. But the numerator is also negative in this case. When ΔT_1 is greater than ΔT_2, we obtain positive numbers at the both numerator and denominator.

13-36C In the parallel-flow heat exchangers the hot and cold fluids enter the heat exchanger at the same end, and the temperature of the hot fluid decreases and the temperature of the cold fluid increases along the heat exchanger. But the temperature of the cold fluid can never exceed that of the hot fluid. In case of the counter-flow heat exchangers the hot and cold fluids enter the heat exchanger from the opposite ends and the outlet temperature of the cold fluid may exceed the outlet temperature of the hot fluid.

13-37C The ΔT_{lm} will be greatest for double-pipe counter-flow heat exchangers.

13-38C The factor F is called as correction factor which depends on the geometry of the heat exchanger and the inlet and the outlet temperatures of the hot and cold fluid streams. It represents how closely a heat exchanger approximates a counter-flow heat exchanger in terms of its logarithmic mean temperature difference. F cannot be greater than unity.

13-39C In this case it is not practical to use the LMTD method because it requires tedious iterations. Instead, the effectiveness-NTU method should be used.

13-40C First heat transfer rate is determined from $\dot{Q} = \dot{m}C_p[T_{in} - T_{out}]$, $\Delta T_{\ln}$ from $\Delta T_{lm} = \dfrac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)}$, correction factor from the figures, and finally the surface area of the heat exchanger from $\dot{Q} = UAFDT_{lm,cf}$

13-41 Steam is condensed by cooling water in the condenser of a power plant. The mass flow rate of the cooling water and the rate of condensation are to be determined.

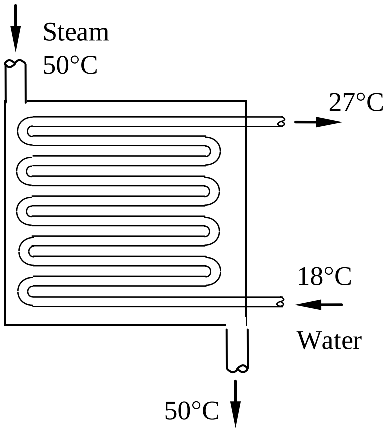
Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant.

Properties The heat of vaporization of water at 50°C is given to be h_{fg} = 2305 kJ/kg and specific heat of cold water at the average temperature of 22.5°C is given to be C_p = 4180 J/kg.°C.

Analysis The temperature differences between the steam and the cooling water at the two ends of the condenser are

$$\Delta T_1 = T_{h,in} - T_{c,out} = 50^\circ\text{C} - 27^\circ\text{C} = 23^\circ\text{C}$$

$$\Delta T_2 = T_{h,out} - T_{c,in} = 50^\circ\text{C} - 18^\circ\text{C} = 32^\circ\text{C}$$



and

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{23-32}{\ln(23/32)} = 27.3^\circ\text{C}$$

Then the heat transfer rate in the condenser becomes

$$\dot{Q} = UA_s\Delta T_{lm} = (2400\ \text{W/m}^2.^\circ\text{C})(58\ \text{m}^2)(27.3^\circ\text{C}) = 3800\ \text{kW}$$

The mass flow rate of the cooling water and the rate of condensation of steam are determined from

$$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{\text{cooling water}}$$

$$\dot{m}_{\substack{\text{cooling}\\\text{water}}} = \frac{\dot{Q}}{C_p(T_{out} - T_{in})} = \frac{3800\ \text{kJ/s}}{(4.18\ \text{kJ/kg.°C})(27°\text{C} - 18°\text{C})} = \mathbf{101 kg/s}$$

$$\dot{Q} = (\dot{m}h_{fg})_{steam} \longrightarrow \dot{m}_{steam} = \frac{\dot{Q}}{h_{fg}} = \frac{3800\ \text{kJ/s}}{2305\ \text{kJ/kg}} = \mathbf{1.65\ kg/s}$$

13-42 Water is heated in a double-pipe parallel-flow heat exchanger by geothermal water. The required length of tube is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant.

Properties The specific heats of water and geothermal fluid are given to be 4.18 and 4.31 kJ/kg.°C, respectively.

Analysis The rate of heat transfer in the heat exchanger is

$$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{\text{water}} = (0.2\text{ kg/s})(4.18\text{ kJ/kg.°C})(60\text{°C} - 25\text{°C}) = 29.26\text{ kW}$$

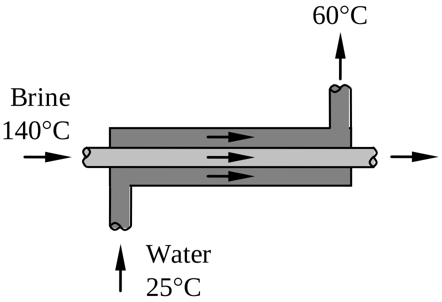
Then the outlet temperature of the geothermal water is determined from

$$\dot{Q} = [\dot{m}C_p(T_{in} - T_{out})]_{\text{geot.water}} \longrightarrow T_{out} = T_{in} - \frac{\dot{Q}}{\dot{m}C_p} = 140\text{°C} - \frac{29.26\text{ kW}}{(0.3\text{ kg/s})(4.31\text{ kJ/kg.°C})} = 117.4\text{°C}$$

The logarithmic mean temperature difference is

$$\Delta T_1 = T_{h,in} - T_{c,in} = 140\text{°C} - 25\text{°C} = 115\text{°C}$$

$$\Delta T_2 = T_{h,out} - T_{c,out} = 117.4\text{°C} - 60\text{°C} = 57.4\text{°C}$$



and

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{115 - 57.4}{\ln(115/57.4)} = 82.9\text{°C}$$

The surface area of the heat exchanger is determined from

$$\dot{Q} = UA_s\Delta T_{lm} \longrightarrow A_s = \frac{\dot{Q}}{U\Delta T_{lm}} = \frac{29.26\text{ kW}}{(0.55\text{ kW/m}^2)(82.9\text{°C})} = 0.642\text{ m}^2$$

Then the length of the tube required becomes

$$A_s = \pi DL \longrightarrow L = \frac{A_s}{\pi D} = \frac{0.642\text{ m}^2}{\pi(0.008\text{ m})} = \mathbf{25.5\text{ m}}$$

13-44E Glycerin is heated by hot water in a 1-shell pass and 8-tube passes heat exchanger. The rate of heat transfer for the cases of fouling and no fouling are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** Heat transfer coefficients and fouling factors are constant and uniform. **5** The thermal resistance of the inner tube is negligible since the tube is thin-walled and highly conductive.

Properties The specific heats of glycerin and water are given to be 0.60 and 1.0 Btu/lbm.°F, respectively.

Analysis (*a*) The tubes are thin walled and thus we assume the inner surface area of the tube to be equal to the outer surface area. Then the heat transfer surface area of this heat exchanger becomes

$$A_s = n\pi DL = 8\pi(0.5/12\text{ ft})(500\text{ ft}) = 523.6\text{ ft}^2$$

The temperature differences at the two ends of the heat exchanger are

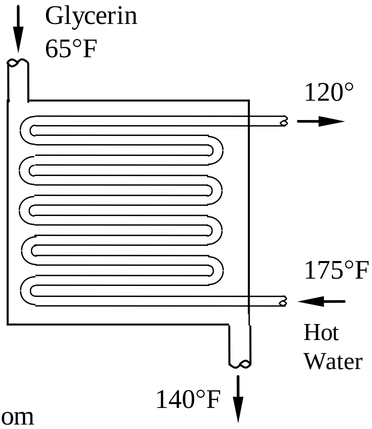
$$\Delta T_1 = T_{h,in} - T_{c,out} = 175°\text{F} - 140°\text{F} = 35°\text{F}$$

$$\Delta T_2 = T_{h,out} - T_{c,in} = 120°\text{F} - 65°\text{F} = 55°\text{F}$$

and $$\Delta T_{lm,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{35-55}{\ln(35/55)} = 44.25°\text{F}$$

The correction factor is

$$\left.\begin{aligned} P &= \frac{t_2 - t_1}{T_1 - t_1} = \frac{120-175}{65-175} = 0.5 \\ R &= \frac{T_1 - T_2}{t_2 - t_1} = \frac{65-140}{120-175} = 1.36 \end{aligned}\right\} F = 0.70$$



In case of no fouling, the overall heat transfer coefficient is determined from

$$U = \frac{1}{\dfrac{1}{h_i} + \dfrac{1}{h_o}} = \frac{1}{\dfrac{1}{50\text{ Btu/h.ft}^2.°\text{F}} + \dfrac{1}{4\text{ Btu/h.ft}^2.°\text{F}}} = 3.7\text{ Btu/h.ft}^2.°\text{F}$$

Then the rate of heat transfer becomes

$$\dot{Q} = UA_s F\Delta T_{lm,CF} = (3.7\text{ Btu/h.ft}^2.°\text{F})(523.6\text{ ft}^2)(0.70)(44.25°\text{F}) = \mathbf{60{,}000\text{ Btu/h}}$$

(*b*) The thermal resistance of the heat exchanger with a fouling factor is

$$\begin{aligned} R &= \frac{1}{h_i A_i} + \frac{R_{fi}}{A_i} + \frac{1}{h_o A_o} \\ &= \frac{1}{(50\text{ Btu/h.ft}^2.°\text{F})(523.6\text{ ft}^2)} + \frac{0.002\text{ h.ft}^2.°\text{F/Btu}}{523.6\text{ ft}^2} + \frac{1}{(4\text{ Btu/h.ft}^2.°\text{F})(523.6\text{ ft}^2)} \\ &= 0.0005195\text{ h.°F/Btu} \end{aligned}$$

The overall heat transfer coefficient in this case is

$$R = \frac{1}{UA_s} \longrightarrow U = \frac{1}{RA_s} = \frac{1}{(0.0005195\text{ h.°F/Btu})(523.6\text{ ft}^2)} = 3.68\text{ Btu/h.ft}^2.°\text{F}$$

Then rate of heat transfer becomes

$$\dot{Q} = UA_s F\Delta T_{lm,CF} = (3.68\text{ Btu/h.ft}^2.°\text{F})(523.6\text{ ft}^2)(0.70)(44.25°\text{F}) = \mathbf{59{,}680\text{ Btu/h}}$$

13-45 During an experiment, the inlet and exit temperatures of water and oil and the mass flow rate of water are measured. The overall heat transfer coefficient based on the inner surface area is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** Fluid properties are constant.

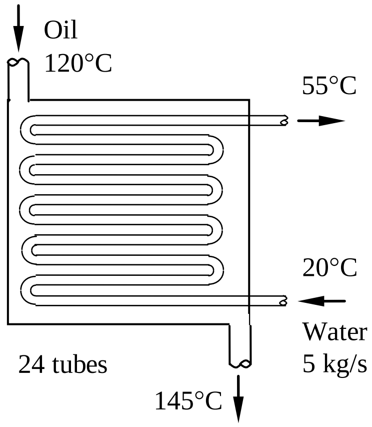
Properties The specific heats of water and oil are given to be 4180 and 2150 J/kg.°C, respectively.

Analysis The rate of heat transfer from the oil to the water is

$$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{\text{water}} = (5\text{ kg/s})(4.18\text{ kJ/kg.°C})(55\text{°C} - 20\text{°C}) = 731.5\text{ kW}$$

The heat transfer area on the tube side is

$$A_i = n\pi D_i L = 24\pi(0.012\text{ m})(2\text{ m}) = 1.8\text{ m}^2$$



The logarithmic mean temperature difference for counter-flow arrangement and the correction factor F are

$$\Delta T_1 = T_{h,in} - T_{c,out} = 120\text{°C} - 55\text{°C} = 65\text{°C}$$

$$\Delta T_2 = T_{h,out} - T_{c,in} = 45\text{°C} - 20\text{°C} = 25\text{°C}$$

$$\Delta T_{lm,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{65 - 25}{\ln(65/25)} = 41.9\text{°C}$$

$$\left.\begin{aligned} P &= \frac{t_2 - t_1}{T_1 - t_1} = \frac{55 - 20}{120 - 20} = 0.35 \\ R &= \frac{T_1 - T_2}{t_2 - t_1} = \frac{120 - 45}{55 - 20} = 2.14 \end{aligned}\right\} F = 0.70$$

Then the overall heat transfer coefficient becomes

$$\dot{Q} = U_i A_i F \Delta T_{lm,CF} \longrightarrow U_i = \frac{\dot{Q}}{A_i F \Delta T_{lm,CF}} = \frac{731.5\text{ kW}}{(1.8\text{ m}^2)(0.70)(41.9\text{°C})} = \mathbf{13.9\ kW/m^2.°C}$$

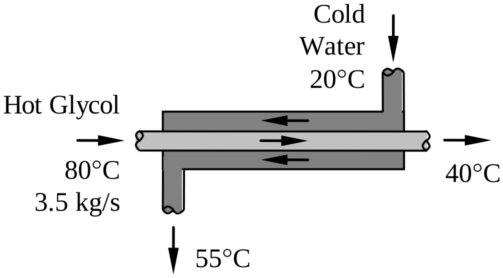
13-46 Ethylene glycol is cooled by water in a double-pipe counter-flow heat exchanger. The rate of heat transfer, the mass flow rate of water, and the heat transfer surface area on the inner side of the tubes are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant.

Properties The specific heats of water and ethylene glycol are given to be 4.18 and 2.56 kJ/kg.°C, respectively.

Analysis (*a*) The rate of heat transfer is

$$\begin{aligned}\dot{Q} &= [\dot{m}C_p(T_{in} - T_{out})]_{\text{glycol}} \\ &= (3.5\text{ kg/s})(2.56\text{ kJ/kg.°C})(80°\text{C} - 40°\text{C}) \\ &= \mathbf{358.4\ kW}\end{aligned}$$



(*b*) The rate of heat transfer from water must be equal to the rate of heat transfer to the glycol. Then,

$$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{\text{water}} \longrightarrow \dot{m}_{\text{water}} = \frac{\dot{Q}}{C_p(T_{out} - T_{in})}$$

$$= \frac{358.4\text{ kJ/s}}{(4.18\text{ kJ/kg.°C})(55°\text{C} - 20°\text{C})} = \mathbf{2.45\ kg/s}$$

(*c*) The temperature differences at the two ends of the heat exchanger are

$$\begin{aligned}\Delta T_1 &= T_{h,in} - T_{c,out} = 80°\text{C} - 55°\text{C} = 25°\text{C} \\ \Delta T_2 &= T_{h,out} - T_{c,in} = 40°\text{C} - 20°\text{C} = 20°\text{C}\end{aligned}$$

and

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{25 - 20}{\ln(25/20)} = 22.4°\text{C}$$

Then the heat transfer surface area becomes

$$\dot{Q} = U_i A_i \Delta T_{lm} \longrightarrow A_i = \frac{\dot{Q}}{U_i \Delta T_{lm}} = \frac{358.4\text{ kW}}{(0.25\text{ kW/m}^2\text{.°C})(22.4°\text{C})} = \mathbf{64.0\ m^2}$$

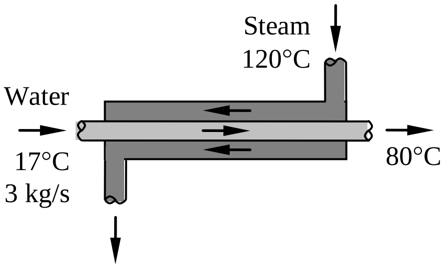
13-47 Water is heated by steam in a double-pipe counter-flow heat exchanger. The required length of the tubes is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant.

Properties The specific heat of water is given to be 4.18 kJ/kg.°C. The heat of condensation of steam at 120°C is given to be 2203 kJ/kg.

Analysis The rate of heat transfer is

$$\begin{aligned}\dot{Q} &= [\dot{m}C_p(T_{out}-T_{in})]_{\text{water}}\\ &= (3\text{ kg/s})(4.18\text{ kJ/kg.°C})(80°\text{C}-17°\text{C})\\ &= 790.02\text{ kW}\end{aligned}$$



The logarithmic mean temperature difference is

$$\Delta T_1 = T_{h,in}-T_{c,out} = 120°\text{C}-80°\text{C} = 40°\text{C}$$

$$\Delta T_2 = T_{h,in}-T_{c,in} = 120°\text{C}-17°\text{C} = 103°\text{C}$$

$$\Delta T_{lm} = \frac{\Delta T_1-\Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{40-103}{\ln(40/103)} = 66.6°\text{C}$$

The heat transfer surface area is

$$\dot{Q} = U_i A_i \Delta T_{lm} \longrightarrow A_i = \frac{\dot{Q}}{U_i \Delta T_{lm}} = \frac{790.02\text{ kW}}{(1.5\text{ kW/m}^2.°\text{C})(66.6°\text{C})} = 7.9\text{ m}^2$$

Then the length of tube required becomes

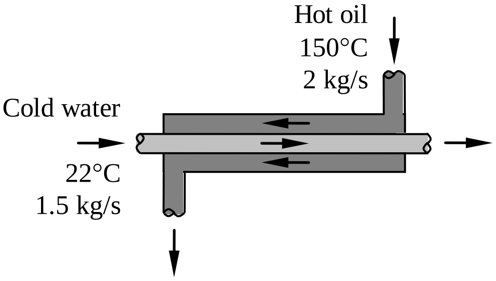
$$A_i = \pi D_i L \longrightarrow L = \frac{A_i}{\pi D_i} = \frac{7.9\text{ m}^2}{\pi(0.025\text{ m})} = \mathbf{100.6\text{ m}}$$

13-48 Oil is cooled by water in a thin-walled double-pipe counter-flow heat exchanger. The overall heat transfer coefficient of the heat exchanger is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant. **6** The thermal resistance of the inner tube is negligible since the tube is thin-walled and highly conductive.

Properties The specific heats of water and oil are given to be 4.18 and 2.20 kJ/kg.°C, respectively.

Analysis The rate of heat transfer from the water to the oil is



$$\begin{aligned}\dot{Q} &= [\dot{m}C_p(T_{in} - T_{out})]_{\text{oil}}\\ &= (2\text{ kg/s})(2.2\text{ kJ/kg.°C})(150\text{°C} - 40\text{°C})\\ &= 484\text{ kW}\end{aligned}$$

The outlet temperature of the water is determined from

$$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{\text{water}} \longrightarrow T_{out} = T_{in} + \frac{\dot{Q}}{\dot{m}C_p}$$

$$= 22^\circ\text{C} + \frac{484\text{ kW}}{(1.5\text{ kg/s})(4.18\text{ kJ/kg.}^\circ\text{C})} = 99.2^\circ\text{C}$$

The logarithmic mean temperature difference is

$$\Delta T_1 = T_{h,in} - T_{c,out} = 150^\circ\text{C} - 99.2^\circ\text{C} = 50.8^\circ\text{C}$$

$$\Delta T_2 = T_{h,out} - T_{c,in} = 40^\circ\text{C} - 22^\circ\text{C} = 18^\circ\text{C}$$

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{50.8 - 18}{\ln(50.8/18)} = 31.6^\circ\text{C}$$

Then the overall heat transfer coefficient becomes

$$U = \frac{\dot{Q}}{A_s \Delta T_{lm}} = \frac{484\text{ kW}}{\pi(0.025\text{ m})(6\text{ m})(31.6\text{°C})} = \mathbf{32.5\ kW/m^2.°C}$$

13-50 The inlet and outlet temperatures of the cold and hot fluids in a double-pipe heat exchanger are given. It is to be determined whether this is a parallel-flow or counter-flow heat exchanger.

Analysis In parallel-flow heat exchangers, the temperature of the cold water can never exceed that of the hot fluid. In this case $T_{\text{cold out}}$ = 50°C which is greater than $T_{\text{hot out}}$ = 45°C. Therefore this must be a counter-flow heat exchanger.

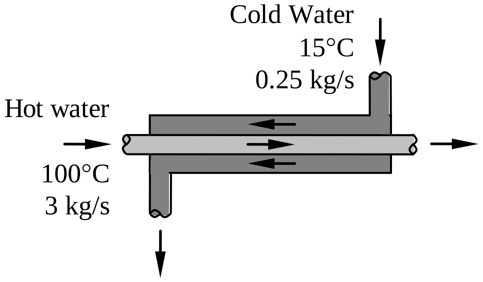
13-51 Cold water is heated by hot water in a double-pipe counter-flow heat exchanger. The rate of heat transfer and the heat transfer surface area of the heat exchanger are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant. **6** The thermal resistance of the inner tube is negligible since the tube is thin-walled and highly conductive.

Properties The specific heats of cold and hot water are given to be 4.18 and 4.19 kJ/kg.°C, respectively.

Analysis The rate of heat transfer in this heat exchanger is

$$\begin{aligned}\dot{Q} &= [\dot{m}C_p(T_{out} - T_{in})]_{\text{cold water}}\\ &= (0.25\text{ kg/s})(4.18\text{ kJ/kg.°C})(45°\text{C} - 15°\text{C})\\ &= \mathbf{31.35\ kW}\end{aligned}$$



The outlet temperature of the hot water is determined from

$$\dot{Q} = [\dot{m}C_p(T_{in} - T_{out})]_{\text{hot water}} \longrightarrow T_{out} = T_{in} - \frac{\dot{Q}}{\dot{m}C_p} = 100°\text{C} - \frac{31.35\text{ kW}}{(3\text{ kg/s})(4.19\text{ kJ/kg.°C})} = 97.5°\text{C}$$

The temperature differences at the two ends of the heat exchanger are

$$\begin{aligned}\Delta T_1 &= T_{h,in} - T_{c,out} = 100°\text{C} - 45°\text{C} = 55°\text{C}\\ \Delta T_2 &= T_{h,out} - T_{c,in} = 97.5°\text{C} - 15°\text{C} = 82.5°\text{C}\end{aligned}$$

and

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{55 - 82.5}{\ln(55/82.5)} = 67.8°\text{C}$$

Then the surface area of this heat exchanger becomes

$$\dot{Q} = UA_s\Delta T_{lm} \longrightarrow A_s = \frac{\dot{Q}}{U\Delta T_{lm}} = \frac{31.35\text{ kW}}{(1.210\text{ kW/m}^2\text{.°C})(67.8°\text{C})} = \mathbf{0.382\ m^2}$$

13-52 Engine oil is heated by condensing steam in a condenser. The rate of heat transfer and the length of the tube required are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant. **6** The thermal resistance of the inner tube is negligible since the tube is thin-walled and highly conductive.

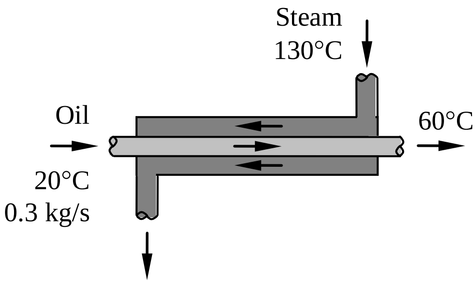
Properties The specific heat of engine oil is given to be 2.1 kJ/kg.°C. The heat of condensation of steam at 130°C is given to be 2174 kJ/kg.

Analysis The rate of heat transfer in this heat exchanger is

$$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{\text{oil}} = (0.3\,\text{kg/s})(2.1\,\text{kJ/kg.°C})(60°\text{C} - 20°\text{C}) = \mathbf{25.2\ kW}$$

The temperature differences at the two ends of the heat exchanger are

$$\Delta T_1 = T_{h,in} - T_{c,out} = 130°\text{C} - 60°\text{C} = 70°\text{C}$$
$$\Delta T_2 = T_{h,out} - T_{c,in} = 130°\text{C} - 20°\text{C} = 110°\text{C}$$



and

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{70 - 110}{\ln(70/110)} = 88.5°\text{C}$$

The surface area is

$$A_s = \frac{\dot{Q}}{U\Delta T_{lm}} = \frac{25.2\,\text{kW}}{(0.65\,\text{kW/m}^2.°\text{C})(88.5°\text{C})} = 0.44\,\text{m}^2$$

Then the length of the tube required becomes

$$A_s = \pi DL \longrightarrow L = \frac{A_s}{\pi D} = \frac{0.44\,\text{m}^2}{\pi(0.02\,\text{m})} = \mathbf{7.0\ m}$$

13-53E Water is heated by geothermal water in a double-pipe counter-flow heat exchanger. The mass flow rate of each fluid and the total thermal resistance of the heat exchanger are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant.

Properties The specific heats of water and geothermal fluid are given to be 1.0 and 1.03 Btu/lbm.°F, respectively.

Analysis The mass flow rate of each fluid are determined from

$$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{\text{water}}$$

$$\dot{m}_{\text{water}} = \frac{\dot{Q}}{C_p(T_{out} - T_{in})} = \frac{30 \text{ Btu/s}}{(1.0 \text{ Btu/lbm.°F})(200\text{°F} - 140\text{°F})} = \mathbf{0.5\ lbm/s}$$

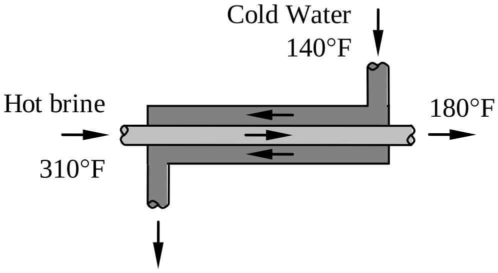
$$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{\text{geo. water}}$$

$$\dot{m}_{\text{geo. water}} = \frac{\dot{Q}}{C_p(T_{out} - T_{in})} = \frac{30 \text{ Btu/s}}{(1.03 \text{ Btu/lbm.°F})(310\text{°F} - 180\text{°F})} = \mathbf{0.224\ lbm/s}$$

The temperature differences at the two ends of the heat exchanger are

$$\Delta T_1 = T_{h,in} - T_{c,out} = 310\text{°F} - 200\text{°F} = 110\text{°F}$$

$$\Delta T_2 = T_{h,out} - T_{c,in} = 180\text{°F} - 140\text{°F} = 40\text{°F}$$



and

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{110 - 40}{\ln(110/40)} = 69.20\text{°F}$$

Then

$$\dot{Q} = UA_s \Delta T_{lm} \longrightarrow UA_s = \frac{\dot{Q}}{\Delta T_{lm}} = \frac{30 \text{ Btu/s}}{69.20\text{°F}} = 0.4335 \text{ Btu/s.}^\text{o}\text{ F}$$

$$U = \frac{1}{RA_s} \longrightarrow R = \frac{1}{UA_s} = \frac{1}{0.4336 \text{ Btu/s.°F}} = \mathbf{2.31\ s.°F/Btu}$$

13-54 Glycerin is heated by ethylene glycol in a thin-walled double-pipe parallel-flow heat exchanger. The rate of heat transfer, the outlet temperature of the glycerin, and the mass flow rate of the ethylene glycol are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant. **6** The thermal resistance of the inner tube is negligible since the tube is thin-walled and highly conductive.

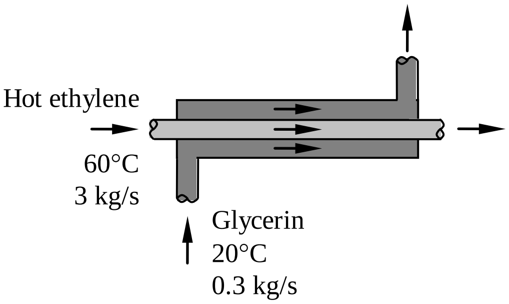
Properties The specific heats of glycerin and ethylene glycol are given to be 2.4 and 2.5 kJ/kg.°C, respectively.

Analysis (*a*) The temperature differences at the two ends are

$$\Delta T_1 = T_{h,in} - T_{c,in} = 60^\circ\text{C} - 20^\circ\text{C} = 40^\circ\text{C}$$

$$\Delta T_2 = T_{h,out} - T_{c,out} = T_{h,out} - (T_{h,out} - 15^\circ\text{C}) = 15^\circ\text{C}$$

and $$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{40-15}{\ln(40/15)} = 25.5^\circ\text{C}$$



Then the rate of heat transfer becomes

$$\dot{Q} = UA_s\Delta T_{lm} = (240\text{ W/m}^2.^\circ\text{C})(3.2\text{ m}^2)(25.5^\circ\text{C}) = 19{,}584\text{ W} = \mathbf{19.58\ kW}$$

(*b*) The outlet temperature of the glycerin is determined from

$$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{\text{glycerin}} \longrightarrow T_{out} = T_{in} + \frac{\dot{Q}}{\dot{m}C_p} = 20^\circ\text{C} + \frac{19.584\text{ kW}}{(0.3\text{ kg/s})(2.4\text{ kJ/kg.}^\circ\text{C})} = \mathbf{47.2^\circ C}$$

(*c*) Then the mass flow rate of ethylene glycol becomes

$$\dot{Q} = [\dot{m}C_p(T_{in} - T_{out})]_{\text{ethylene glycol}}$$

$$\dot{m}_{\text{ethylene glycol}} = \frac{\dot{Q}}{C_p(T_{in} - T_{out})} = \frac{19.584\text{ kJ/s}}{(2.5\text{ kJ/kg.}^\circ\text{C})[(47.2+15)^\circ\text{C} - 60^\circ\text{C}]} = \mathbf{3.56\ kg/s}$$

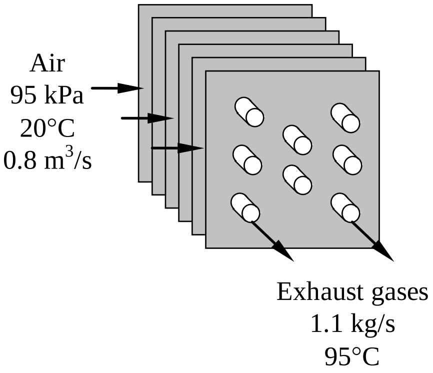
13-55 Air is preheated by hot exhaust gases in a cross-flow heat exchanger. The rate of heat transfer and the outlet temperature of the air are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant.

Properties The specific heats of air and combustion gases are given to be 1005 and 1100 J/kg.°C, respectively.

Analysis The rate of heat transfer is

$$\begin{aligned}\dot{Q} &= [\dot{m}C_p(T_{in}-T_{out})]_{\text{gas.}}\\ &= (1.1\text{ kg/s})(1.1\text{ kJ/kg.°C})(180°\text{C}-95°\text{C})\\ &= \mathbf{103\ kW}\end{aligned}$$



The mass flow rate of air is

$$\dot{m} = \frac{P\dot{V}}{RT} = \frac{(95\text{ kPa})(0.8\text{ m}^3/\text{s})}{(0.287\text{ kPa.m}^3/\text{kg.K})\times 293\text{ K}} = 0.904\text{ kg/s}$$

Then the outlet temperature of the air becomes

$$\dot{Q} = \dot{m}C_p(T_{c,out}-T_{c,in})$$

$$T_{c,out} = T_{c,in} + \frac{\dot{Q}}{\dot{m}C_p} = 20°\text{C} + \frac{103\times 10^3\text{ W}}{(0.904\text{ kg/s})(1005\text{ J/kg.°C})} = \mathbf{133°C}$$

13-56 Water is heated by hot oil in a 2-shell passes and 12-tube passes heat exchanger. The heat transfer surface area on the tube side is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant.

Properties The specific heats of water and oil are given to be 4.18 and 2.3 kJ/kg.°C, respectively.

Analysis The rate of heat transfer in this heat exchanger is

$$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{\text{water}} = (4.5\text{ kg/s})(4.18\text{ kJ/kg.°C})(70\text{°C} - 20\text{°C}) = 940.5\text{ kW}$$

The outlet temperature of the hot water is determined from

$$\dot{Q} = [\dot{m}C_p(T_{in} - T_{out})]_{\text{oil}} \longrightarrow T_{out} = T_{in} - \frac{\dot{Q}}{\dot{m}C_p} = 170\text{°C} - \frac{940.5\text{ kW}}{(10\text{ kg/s})(2.3\text{ kJ/kg.°C})} = 129\text{°C}$$

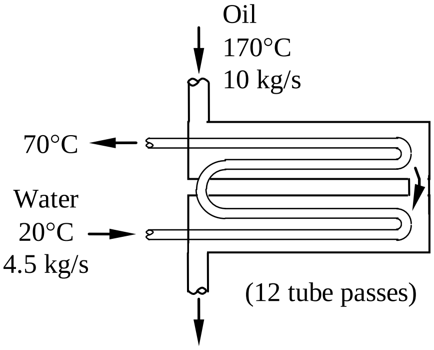
The logarithmic mean temperature difference for counter-flow arrangement and the correction factor F are

$$\Delta T_1 = T_{h,in} - T_{c,out} = 170\text{°C} - 70\text{°C} = 100\text{°C}$$

$$\Delta T_2 = T_{h,out} - T_{c,in} = 129\text{°C} - 20\text{°C} = 109\text{°C}$$

$$\Delta T_{lm,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{100 - 109}{\ln(100/109)} = 105\text{°C}$$

$$\left.\begin{aligned} P &= \frac{t_2 - t_1}{T_1 - t_1} = \frac{129 - 170}{20 - 170} = 0.27 \\ R &= \frac{T_1 - T_2}{t_2 - t_1} = \frac{20 - 70}{129 - 170} = 1.2 \end{aligned}\right\} F = 1.0$$



Then the heat transfer surface area on the tube side becomes

$$\dot{Q} = UA_s F\Delta T_{lm,CF} \longrightarrow A_s = \frac{\dot{Q}}{UF\Delta T_{lm,CF}} = \frac{940.5\text{ kW}}{(0.6\text{ kW/m}^2.\text{°C})(1.0)(105\text{°C})} = \mathbf{15\ m^2}$$

13-57 Water is heated by hot oil in a 2-shell passes and 12-tube passes heat exchanger. The heat transfer surface area on the tube side is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant.

Properties The specific heats of water and oil are given to be 4.18 and 2.3 kJ/kg.°C, respectively.

Analysis The rate of heat transfer in this heat exchanger is

$$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{\text{water}} = (2\text{ kg/s})(4.18\text{ kJ/kg.°C})(70\text{°C} - 20\text{°C}) = 418\text{ kW}$$

The outlet temperature of the oil is determined from

$$\dot{Q} = [\dot{m}C_p(T_{in} - T_{out})]_{\text{oil}} \longrightarrow T_{out} = T_{in} - \frac{\dot{Q}}{\dot{m}C_p} = 170\text{°C} - \frac{418\text{ kW}}{(10\text{ kg/s})(2.3\text{ kJ/kg.°C})} = 151.8\text{°C}$$

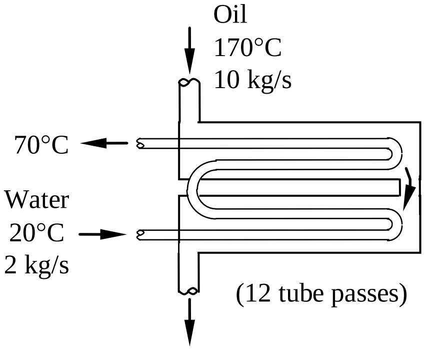
The logarithmic mean temperature difference for counter-flow arrangement and the correction factor F are

$$\Delta T_1 = T_{h,in} - T_{c,out} = 170\text{°C} - 70\text{°C} = 100\text{°C}$$

$$\Delta T_2 = T_{h,out} - T_{c,in} = 151.8\text{°C} - 20\text{°C} = 131.8\text{°C}$$

$$\Delta T_{lm,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{100 - 131.8}{\ln(100/131.8)} = 115.2\text{°C}$$

$$\left.\begin{aligned} P &= \frac{t_2 - t_1}{T_1 - t_1} = \frac{151.8 - 170}{20 - 170} = 0.12 \\ R &= \frac{T_1 - T_2}{t_2 - t_1} = \frac{20 - 70}{151.8 - 170} = 2.7 \end{aligned}\right\} F = 1.0$$



Then the heat transfer surface area on the tube side becomes

$$\dot{Q} = U_i A_i F\Delta T_{lm,CF} \longrightarrow A_i = \frac{\dot{Q}}{U_i F\Delta T_{lm,CF}} = \frac{418\text{ kW}}{(0.6\text{ kW/m}^2\text{.°C})(1.0)(115.2\text{°C})} = \mathbf{6.05\ m^2}$$

13-58 Ethyl alcohol is heated by water in a 2-shell passes and 8-tube passes heat exchanger. The heat transfer surface area of the heat exchanger is to be determined.

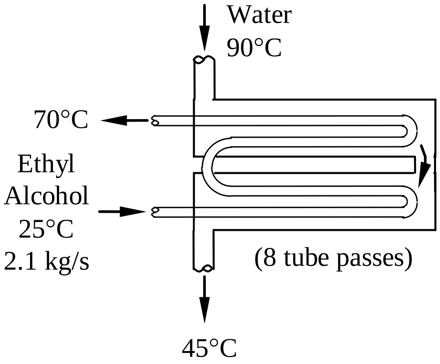
Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant.

Properties The specific heats of water and ethyl alcohol are given to be 4.19 and 2.67 kJ/kg.°C, respectively.

Analysis The rate of heat transfer in this heat exchanger is

$$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{\text{ethyl alcohol}} = (2.1\,\text{kg/s})(2.67\,\text{kJ/kg.°C})(70°\text{C} - 25°\text{C}) = 252.3\,\text{kW}$$

The logarithmic mean temperature difference for counter-flow arrangement and the correction factor F are



$$\Delta T_1 = T_{h,in} - T_{c,out} = 95°\text{C} - 70°\text{C} = 25°\text{C}$$

$$\Delta T_2 = T_{h,out} - T_{c,in} = 45°\text{C} - 25°\text{C} = 20°\text{C}$$

$$\Delta T_{lm,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{25-20}{\ln(25/20)} = 22.4°\text{C}$$

$$\left.\begin{aligned} P &= \frac{t_2 - t_1}{T_1 - t_1} = \frac{45-95}{25-95} = 0.7 \\ R &= \frac{T_1 - T_2}{t_2 - t_1} = \frac{25-70}{45-95} = 0.9 \end{aligned}\right\} F = 0.77$$

Then the heat transfer surface area on the tube side becomes

$$\dot{Q} = U_i A_i F \Delta T_{lm,CF} \longrightarrow A_i = \frac{\dot{Q}}{U_i F \Delta T_{lm,CF}} = \frac{252.3\,\text{kW}}{(0.950\,\text{kW/m}^2.°\text{C})(0.77)(22.4°\text{C})} = \mathbf{15.4\ m^2}$$

13-59 Water is heated by ethylene glycol in a 2-shell passes and 12-tube passes heat exchanger. The rate of heat transfer and the heat transfer surface area on the tube side are to be determined.

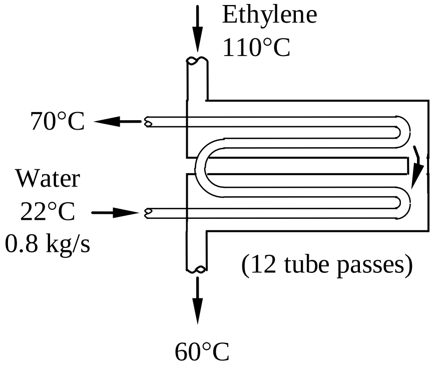
Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant.

Properties The specific heats of water and ethylene glycol are given to be 4.18 and 2.68 kJ/kg.°C, respectively.

Analysis The rate of heat transfer in this heat exchanger is :

$$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{\text{water}} = (0.8\text{ kg/s})(4.18\text{ kJ/kg.°C})(70°\text{C} - 22°\text{C}) = \mathbf{160.5\ kW}$$

The logarithmic mean temperature difference for counter-flow arrangement and the correction factor F are



$$\Delta T_1 = T_{h,in} - T_{c,out} = 110°\text{C} - 70°\text{C} = 40°\text{C}$$

$$\Delta T_2 = T_{h,out} - T_{c,in} = 60°\text{C} - 22°\text{C} = 38°\text{C}$$

$$\Delta T_{lm,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{40-38}{\ln(40/38)} = 39°\text{C}$$

$$\left.\begin{aligned} P &= \frac{t_2 - t_1}{T_1 - t_1} = \frac{60-110}{22-110} = 0.57 \\ R &= \frac{T_1 - T_2}{t_2 - t_1} = \frac{22-70}{60-110} = 0.96 \end{aligned}\right\} F = 0.94$$

Then the heat transfer surface area on the tube side becomes

$$\dot{Q} = U_i A_i F \Delta T_{lm,CF} \longrightarrow A_i = \frac{\dot{Q}}{U_i F \Delta T_{lm,CF}} = \frac{160.5\text{ kW}}{(0.28\text{ kW/m}^2.°\text{C})(0.94)(39°\text{C})} = \mathbf{15.6\ m^2}$$

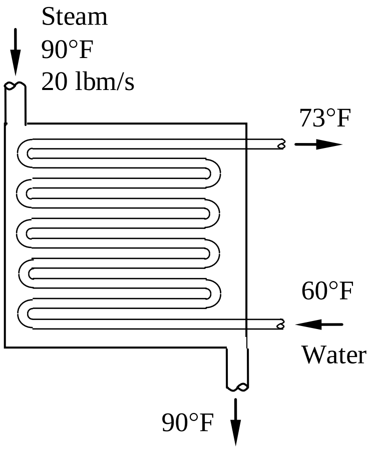
13-61E Steam is condensed by cooling water in a condenser. The rate of heat transfer, the rate of condensation of steam, and the mass flow rate of cold water are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant. **6** The thermal resistance of the inner tube is negligible since the tube is thin-walled and highly conductive.



Properties We take specific heat of water are given to be 1.0 Btu/lbm.°F. The heat of condensation of steam at 90°F is 1043 Btu/lbm.

Analysis (*a*) The log mean temperature difference is determined from

$$\Delta T_1 = T_{h,in} - T_{c,out} = 90°\text{ F} - 73°\text{ F} = 17°\text{ F}$$

$$\Delta T_2 = T_{h,out} - T_{c,in} = 90°\text{ F} - 60°\text{ F} = 30°\text{ F}$$

$$\Delta T_{lm,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{17 - 30}{\ln(17/30)} = 22.9°\text{ F}$$

The heat transfer surface area is

$$A_s = 8n\pi DL = 8 \times 50 \times \pi(3/48\text{ ft})(5\text{ ft}) = 392.7\text{ ft}^2$$

and

$$\dot{Q} = UA_s \Delta T_{lm} = (600\text{ Btu/h.ft}^2.°\text{F})(392.7\text{ ft}^2)(22.9°\text{F}) = \mathbf{5.396 \times 10^6\ Btu/h}$$

(*b*) The rate of condensation of the steam is

$$\dot{Q} = (\dot{m}h_{fg})_{steam} \longrightarrow \dot{m}_{steam} = \frac{\dot{Q}}{h_{fg}} = \frac{5.396 \times 10^6\text{ Btu/h}}{1043\text{ Btu/lbm}} = \mathbf{5173\ lbm/h = 1.44\ lbm/s}$$

(*c*) Then the mass flow rate of cold water becomes

$$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{\text{cold water}}$$

$$\dot{m}_{\text{cold water}} = \frac{\dot{Q}}{C_p(T_{out} - T_{in})} = \frac{5.396 \times 10^6\text{ Btu/h}}{(1.0\text{ Btu/lbm.°F})(73°\text{F} - 60°\text{F}]} = \mathbf{4.15 \times 10^5\ lbm/h} = \mathbf{115\ lbm/s}$$

13-63 Glycerin is heated by hot water in a 1-shell pass and 13-tube passes heat exchanger. The mass flow rate of glycerin and the overall heat transfer coefficient of the heat exchanger are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant.

Properties The specific heats of water and glycerin are given to be 4.18 and 2.48 kJ/kg.°C, respectively.

Analysis The rate of heat transfer in this heat exchanger is

$$\dot{Q} = [\dot{m}C_p(T_{in} - T_{out})]_{\text{water}} = (5 \text{ kg/s})(4.18 \text{ kJ/kg.°C})(100\text{°C} - 55\text{°C}) = 940.5 \text{ kW}$$

The mass flow rate of the glycerin is determined from

$$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{\text{glycerin}}$$

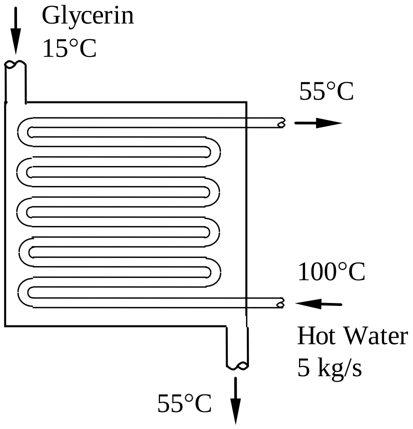
$$\dot{m}_{\text{glycerin}} = \frac{\dot{Q}}{C_p(T_{out} - T_{in})} = \frac{940.5 \text{ kJ/s}}{(2.48 \text{ kJ/kg.°C})[(55\text{°C} - 15\text{°C}]} = \mathbf{9.5\ kg/s}$$

The logarithmic mean temperature difference for counter-flow arrangement and the correction factor F are

$$\Delta T_1 = T_{h,in} - T_{c,out} = 100\text{°C} - 55\text{°C} = 45\text{°C}$$
$$\Delta T_2 = T_{h,out} - T_{c,in} = 55\text{°C} - 15\text{°C} = 40\text{°C}$$

$$\Delta T_{lm,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{45-40}{\ln(45/40)} = 42.5\text{°C}$$

$$\left.\begin{aligned} P &= \frac{t_2 - t_1}{T_1 - t_1} = \frac{55-100}{15-100} = 0.53 \\ R &= \frac{T_1 - T_2}{t_2 - t_1} = \frac{15-55}{55-100} = 0.89 \end{aligned}\right\} F = 0.77$$



The heat transfer surface area is

$$A_s = n\pi DL = 10\pi(0.015 \text{ m})(2 \text{ m}) = 0.94 \text{ m}^2$$

Then the overall heat transfer coefficient of the heat exchanger is determined to be

$$\dot{Q} = UA_s F\Delta T_{lm,CF} \longrightarrow U = \frac{\dot{Q}}{A_s F\Delta T_{lm,CF}} = \frac{940.5 \text{ kW}}{(0.94 \text{ m}^2)(0.77)(42.5\text{°C})} = \mathbf{30.6\ kW/m^2.°C}$$

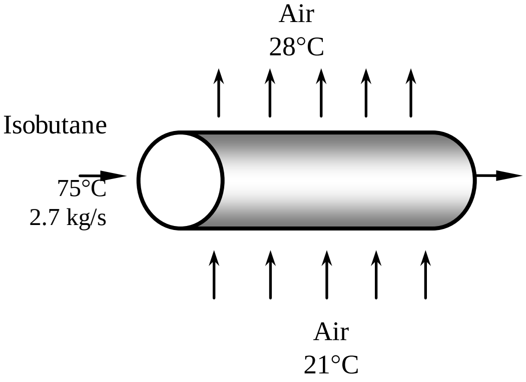
13-64 Isobutane is condensed by cooling air in the condenser of a power plant. The mass flow rate of air and the overall heat transfer coefficient are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant.

Properties The heat of vaporization of isobutane at 75°C is given to be h_{fg} = 255.7 kJ/kg and specific heat of air is given to be C_p = 1005 J/kg.°C.

Analysis First, the rate of heat transfer is determined from

$$\dot{Q} = (\dot{m}h_{fg})_{\text{isobutane}} = (2.7\text{ kg/s})(255.7\text{ kJ/kg}) = 690.39\text{ kW}$$



The mass flow rate of air is determined from

$$\dot{Q} = [\dot{m}C_p(T_{\text{out}} - T_{\text{in}})]_{\text{air}}$$

$$\dot{m}_{\text{air}} = \frac{\dot{Q}}{C_p(T_{\text{out}} - T_{\text{in}})} = \frac{690.39\text{ kJ/s}}{(1.005\text{ kJ/kg.°C})(28\text{°C} - 21\text{°C})} = \mathbf{98.14\ kg/s}$$

The temperature differences between the isobutane and the air at the two ends of the condenser are

$$\Delta T_1 = T_{\text{h,in}} - T_{\text{c,out}} = 75\text{°C} - 21\text{°C} = 54\text{°C}$$
$$\Delta T_2 = T_{\text{h,out}} - T_{\text{c,in}} = 75\text{°C} - 28\text{°C} = 47\text{°C}$$

and

$$\Delta T_{\text{lm}} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{54 - 47}{\ln(54/47)} = 50.4\text{°C}$$

Then the overall heat transfer coefficient is determined from

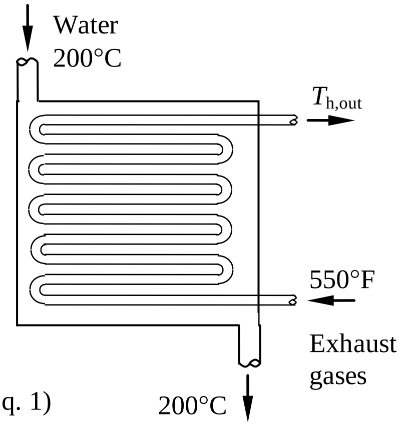
$$\dot{Q} = UA_s\Delta T_{\text{lm}} \longrightarrow 690{,}390\text{ W} = U(24\text{ m}^2)(50.4\text{°C}) \longrightarrow U = \mathbf{571\ W/m^2.°C}$$

13-65 Water is evaporated by hot exhaust gases in an evaporator. The rate of heat transfer, the exit temperature of the exhaust gases, and the rate of evaporation of water are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant.

Properties The heat of vaporization of water at 200°C is given to be h_{fg} = 1941 kJ/kg and specific heat of exhaust gases is given to be C_p = 1051 J/kg.°C.

Analysis The temperature differences between the water and the exhaust gases at the two ends of the evaporator are



$$\Delta T_1 = T_{h,in} - T_{c,out} = 550°\text{C} - 200°\text{C} = 350°\text{C}$$
$$\Delta T_2 = T_{h,out} - T_{c,in} = (T_{h,out} - 200)°\text{C}$$

and

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{350 - (T_{h,out} - 200)}{\ln\left[350/(T_{h,out} - 200)\right]}$$

Then the rate of heat transfer can be expressed as

$$\dot{Q} = UA_s\Delta T_{lm} = (1.780\ \text{kW/m}^2.°\text{C})(0.5\ \text{m}^2)\frac{350 - (T_{h,out} - 200)}{\ln\left[350/(T_{h,out} - 200)\right]} \quad \text{(Eq. 1)}$$

The rate of heat transfer can also be expressed as in the following forms

$$\dot{Q} = [\dot{m}C_p(T_{h,in} - T_{h,out})]_{\substack{\text{exhaust}\\ \text{gases}}} = (0.25\ \text{kg/s})(1.051\ \text{kJ/kg.°C})(550°\text{C} - T_{h,out}) \quad \text{(Eq. 2)}$$

$$\dot{Q} = (\dot{m}h_{fg})_{\text{water}} = \dot{m}_{\text{water}}(1941\ \text{kJ/kg}) \quad \text{(Eq. 3)}$$

We have three equations with three unknowns. Using an equation solver such as EES, the unknowns are determined to be

$$\dot{Q} = \mathbf{88.85\ kW}$$
$$T_{h,out} = \mathbf{211.8°C}$$
$$\dot{m}_{water} = \mathbf{0.0458\ kg/s}$$

13-67 The waste dyeing water is to be used to preheat fresh water. The outlet temperatures of each fluid and the mass flow rate are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** There is no fouling. **5** Fluid properties are constant.

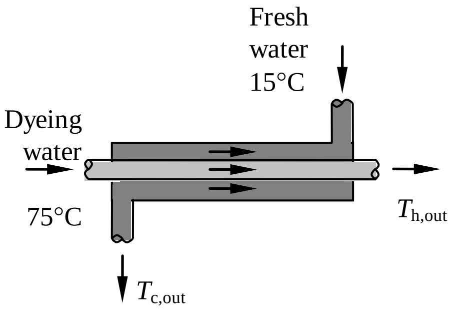
Properties The specific heats of waste dyeing water and the fresh water are given to be C_p = 4295 J/kg.°C and C_p = 4180 J/kg.°C, respectively.

Analysis The temperature differences between the dyeing water and the fresh water at the two ends of the heat exchanger are

$$\Delta T_1 = T_{\text{h,in}} - T_{\text{c,out}} = 75 - T_{\text{c,out}}$$
$$\Delta T_2 = T_{\text{h,out}} - T_{\text{c,in}} = T_{\text{h,out}} - 15$$

and

$$\Delta T_{\text{lm}} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{(75 - T_{\text{c,out}}) - (T_{\text{h,out}} - 15)}{\ln\left[(75 - T_{\text{c,out}})/(T_{\text{h,out}} - 15)\right]}$$



Then the rate of heat transfer can be expressed as

$$\dot{Q} = UA_s\Delta T_{\text{lm}}$$
$$35\text{ kW} = (0.625\text{ kW/m}^2.°\text{C})(1.65\text{ m}^2)\frac{(75 - T_{\text{c,out}}) - (T_{\text{h,out}} - 15)}{\ln\left[(75 - T_{\text{c,out}})/(T_{\text{h,out}} - 15)\right]} \qquad \text{(Eq. 1)}$$

The rate of heat transfer can also be expressed as

$$\dot{Q} = [\dot{m}C_p(T_{\text{h,in}} - T_{\text{h,out}})]_{\substack{\text{dyeing}\\ \text{water}}} \longrightarrow 35\text{ kW} = \dot{m}(4.295\text{ kJ/kg.°C})(75°\text{C} - T_{\text{h,out}}) \quad \text{(Eq. 2)}$$

$$\dot{Q} = [\dot{m}C_p(T_{\text{h,in}} - T_{\text{h,out}})]_{\substack{\text{dyeing}\\ \text{water}}} \longrightarrow 35\text{ kW} = \dot{m}(4.18\text{ kJ/kg.°C})(T_{\text{c,out}} - 15°\text{C}) \quad \text{(Eq. 3)}$$

We have three equations with three unknowns. Using an equation solver such as EES, the unknowns are determined to be

$$T_{\text{c,out}} = \mathbf{41.4°C}$$
$$T_{\text{h,out}} = \mathbf{49.3°C}$$
$$\dot{m} = \mathbf{0.317\ kg/s}$$

The Effectiveness-NTU Method

13-68C When the heat transfer surface area A of the heat exchanger is known, but the outlet temperatures are not, the effectiveness-NTU method is definitely preferred.

13-69C The effectiveness of a heat exchanger is defined as the ratio of the actual heat transfer rate to the maximum possible heat transfer rate and represents how closely the heat transfer in the heat exchanger approaches to maximum possible heat transfer. Since the actual heat transfer rate can not be greater than maximum possible heat transfer rate, the effectiveness can not be greater than one. The effectiveness of a heat exchanger depends on the geometry of the heat exchanger as well as the flow arrangement.

13-70C For a specified fluid pair, inlet temperatures and mass flow rates, the counter-flow heat exchanger will have the highest effectiveness.

13-71C Once the effectiveness ε is known, the rate of heat transfer and the outlet temperatures of cold and hot fluids in a heat exchanger are determined from

$$\dot{Q} = \varepsilon\dot{Q}_{\max} = \varepsilon C_{\min}(T_{h,in} - T_{c,in})$$
$$\dot{Q} = \dot{m}_c C_{p,c}(T_{c,out} - T_{c,in})$$
$$\dot{Q} = \dot{m}_h C_{p,h}(T_{h,in} - T_{h,out})$$

13-72C The heat transfer in a heat exchanger will reach its maximum value when the hot fluid is cooled to the inlet temperature of the cold fluid. Therefore, the temperature of the hot fluid cannot drop below the inlet temperature of the cold fluid at any location in a heat exchanger.

13-73C The heat transfer in a heat exchanger will reach its maximum value when the cold fluid is heated to the inlet temperature of the hot fluid. Therefore, the temperature of the cold fluid cannot rise above the inlet temperature of the hot fluid at any location in a heat exchanger.

13-74C The fluid with the lower mass flow rate will experience a larger temperature change. This is clear from the relation

$$\dot{Q} = \dot{m}_c C_p \Delta T_{cold} = \dot{m}_h C_p \Delta T_{hot}$$

13-75C The maximum possible heat transfer rate is in a heat exchanger is determined from

$$\dot{Q}_{\max} = C_{\min}(T_{h,in} - T_{c,in})$$

where $C_{\min}$ is the smaller heat capacity rate. The value of $\dot{Q}_{\max}$ does not depend on the type of heat exchanger.

13-76C The longer heat exchanger is more likely to have a higher effectiveness.

13-77C The increase of effectiveness with NTU is not linear. The effectiveness increases rapidly with NTU for small values (up to abo ut NTU = 1.5), but rather slowly for larger values. Therefore, the effectiveness will not double when the length of heat exchanger is doubled.

13-78C A heat exchanger has the smallest effectiveness value when the heat capacity rates of two fluids are identical. Therefore, reducing the mass flow rate of cold fluid by half will increase its effectiveness.

13-79C When the capacity ratio is equal to zero and the number of transfer units value is greater than 5, a counter-flow heat exchanger has an effectiveness of one. In this case the exit temperature of the fluid with smaller capacity rate will equal to inlet temperature of the other fluid. For a parallel-flow heat exchanger the answer would be the same.

13-80C The NTU of a heat exchanger is defined as $NTU = \frac{UA_s}{C_{\min}} = \frac{UA_s}{(\dot{m}C_p)_{\min}}$ where U is the overall heat transfer coefficient and A_s is the heat transfer surface area of the heat exchanger. For specified values of U and $C_{\min}$, the value of NTU is a measure of the heat exchanger surface area A_s. Because the effectiveness increases slowly for larger values of NTU, a large heat exchanger cannot be justified economically. Therefore, a heat exchanger with a very large NTU is not necessarily a good one to buy.

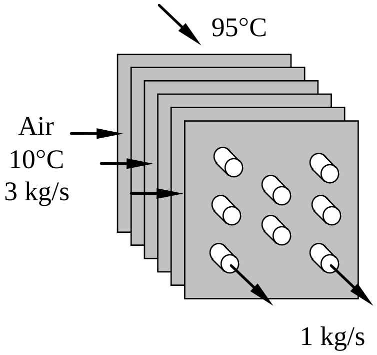
13-81C The value of effectiveness increases slowly with a large values of NTU (usually larger than 3). Therefore, doubling the size of the heat exchanger will not save much energy in this case since the increase in the effectiveness will be very small.

13-82C The value of effectiveness increases rapidly with a small values of NTU (up to about 1.5). Therefore, tripling the NTU will cause a rapid increase in the effectiveness of the heat exchanger, and thus saves energy. I would support this proposal.

13-83 Air is heated by a hot water stream in a cross-flow heat exchanger. The maximum heat transfer rate and the outlet temperatures of the cold and hot fluid streams are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** Fluid properties are constant.

Properties The specific heats of water and air are given to be 4.19 and 1.005 kJ/kg.°C.



Analysis The heat capacity rates of the hot and cold fluids are

$$C_h = \dot{m}_h C_{ph} = (1\text{ kg/s})(4190\text{ J/kg.°C}) = 4190\text{ W/°C}$$

$$C_c = \dot{m}_c C_{pc} = (3\text{ kg/s})(1005\text{ J/kg.°C}) = 3015\text{ W/°C}$$

Therefore

$$C_{\min} = C_c = 3015\text{ W/°C}$$

which is the smaller of the two heat capacity rates. Then the maximum heat transfer rate becomes

$$\dot{Q}_{\max} = C_{\min}(T_{h,in} - T_{c,in}) = (3015\text{ W/°C})(95\text{°C} - 10\text{°C}) = 256,275\text{ W} = \mathbf{256.3\ kW}$$

The outlet temperatures of the cold and the hot streams in this limiting case are determined to be

$$\dot{Q} = C_c(T_{c,out} - T_{c,in}) \longrightarrow T_{c,out} = T_{c,in} + \frac{\dot{Q}}{C_c} = 10\text{°C} + \frac{256.275\text{ kW}}{3.015\text{ kW/°C}} = \mathbf{95°C}$$

$$\dot{Q} = C_h(T_{h,in} - T_{h,out}) \longrightarrow T_{h,out} = T_{h,in} - \frac{\dot{Q}}{C_h} = 95\text{°C} - \frac{256.275\text{ kW}}{4.19\text{ kW/°C}} = \mathbf{33.8°C}$$

13-84 Hot oil is to be cooled by water in a heat exchanger. The mass flow rates and the inlet temperatures are given. The rate of heat transfer and the outlet temperatures are to be determined. √

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The thickness of the tube is negligible since it is thin-walled. **5** The overall heat transfer coefficient is constant and uniform.

Properties The specific heats of the water and oil are given to be 4.18 and 2.2 kJ/kg.°C, respectively.

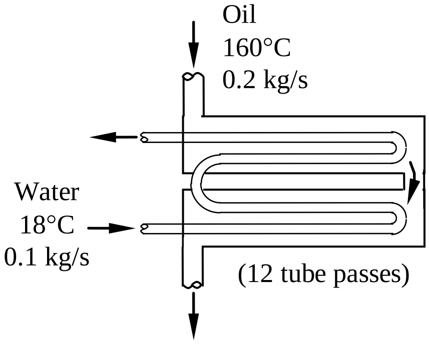
Analysis The heat capacity rates of the hot and cold fluids are

$$C_h = \dot{m}_h C_{ph} = (0.2\text{ kg/s})(2200\text{ J/kg.°C}) = 440\text{ W/°C}$$

$$C_c = \dot{m}_c C_{pc} = (0.1\text{ kg/s})(4180\text{ J/kg.°C}) = 418\text{ W/°C}$$

Therefore, $C_{\min} = C_c = 418\text{ W/°C}$

and $C = \dfrac{C_{\min}}{C_{\max}} = \dfrac{418}{440} = 0.95$



Then the maximum heat transfer rate becomes

$$\dot{Q}_{\max} = C_{\min}(T_{h,in} - T_{c,in}) = (418\text{ W/°C})(160°\text{C} - 18°\text{C}) = 59.36\text{ kW}$$

The heat transfer surface area is

$$A_s = n(\pi DL) = (12)(\pi)(0.018\text{ m})(3\text{ m}) = 2.04\text{ m}^2$$

The NTU of this heat exchanger is

$$NTU = \frac{UA_s}{C_{\min}} = \frac{(340\text{ W/m}^2.°\text{C})\,(2.04\text{ m}^2)}{418\text{ W/°C}} = 1.659$$

Then the effectiveness of this heat exchanger corresponding to C = 0.95 and NTU = 1.659 is determined from Fig. 13-26d to be

$$\varepsilon = 0.61$$

Then the actual rate of heat transfer becomes

$$\dot{Q} = \varepsilon \dot{Q}_{\max} = (0.61)(59.36\text{ kW}) = \mathbf{36.2\text{ kW}}$$

Finally, the outlet temperatures of the cold and hot fluid streams are determined to be

$$\dot{Q} = C_c(T_{c,out} - T_{c,in}) \longrightarrow T_{c,out} = T_{c,in} + \frac{\dot{Q}}{C_c} = 18°\text{C} + \frac{36.2\text{ kW}}{0.418\text{ kW/°C}} = \mathbf{104.6°C}$$

$$\dot{Q} = C_h(T_{h,in} - T_{h,out}) \longrightarrow T_{h,out} = T_{h,in} - \frac{\dot{Q}}{C_h} = 160°\text{C} - \frac{36.2\text{ kW}}{0.44\text{ kW/°C}} = \mathbf{77.7°C}$$

13-85 Inlet and outlet temperatures of the hot and cold fluids in a double-pipe heat exchanger are given. It is to be determined whether this is a parallel-flow or counter-flow heat exchanger and the effectiveness of it.

Analysis This is a counter-flow heat exchanger because in the parallel-flow heat exchangers the outlet temperature of the cold fluid (55°C in this case) cannot exceed the outlet temperature of the hot fluid, which is (45°C in this case). Noting that the mass flow rates of both hot and cold oil streams are the same, we have $C_{\min} = C_{\max} = C$. Then the effectiveness of this heat exchanger is determined from

$$\varepsilon = \frac{\dot{Q}}{\dot{Q}_{\max}} = \frac{C_h(T_{h,in} - T_{h,out})}{C_{\min}(T_{h,in} - T_{c,in})} = \frac{C_h(T_{h,in} - T_{h,out})}{C_h(T_{h,in} - T_{c,in})} = \frac{80^\circ\text{C} - 45^\circ\text{C}}{80^\circ\text{C} - 20^\circ\text{C}} = \mathbf{0.583}$$

13-86E Inlet and outlet temperatures of the hot and cold fluids in a double-pipe heat exchanger are given. It is to be determined the fluid, which has the smaller heat capacity rate and the effectiveness of the heat exchanger.

Analysis Hot water has the smaller heat capacity rate since it experiences a greater temperature change. The effectiveness of this heat exchanger is determined from

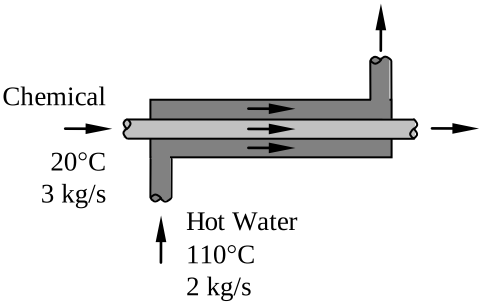
$$\varepsilon = \frac{\dot{Q}}{\dot{Q}_{\max}} = \frac{C_h(T_{h,in} - T_{h,out})}{C_{\min}(T_{h,in} - T_{c,in})} = \frac{C_h(T_{h,in} - T_{h,out})}{C_h(T_{h,in} - T_{c,in})} = \frac{220^\circ\text{F} - 100^\circ\text{F}}{220^\circ\text{F} - 70^\circ\text{F}} = \mathbf{0.8}$$

13-87 A chemical is heated by water in a heat exchanger. The mass flow rates and the inlet temperatures are given. The outlet temperatures of both fluids are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The thickness of the tube is negligible since tube is thin-walled. **5** The overall heat transfer coefficient is constant and uniform.

Properties The specific heats of the water and chemical are given to be 4.18 and 1.8 kJ/kg.°C, respectively.

Analysis The heat capacity rates of the hot and cold fluids are



$$C_h = \dot{m}_h C_{ph} = (2\text{ kg/s})(4.18\text{ kJ/kg.°C}) = 8.36\text{ kW/°C}$$

$$C_c = \dot{m}_c C_{pc} = (3\text{ kg/s})(1.8\text{ kJ/kg.°C}) = 5.40\text{ kW/°C}$$

Therefore, $C_{\min} = C_c = 5.4\text{ kW/°C}$

and $C = \dfrac{C_{\min}}{C_{\max}} = \dfrac{5.40}{8.36} = 0.646$

Then the maximum heat transfer rate becomes

$$\dot{Q}_{\max} = C_{\min}(T_{h,in} - T_{c,in}) = (5.4\text{ kW/°C})(110\text{°C} - 20\text{°C}) = 486\text{ kW}$$

The NTU of this heat exchanger is

$$NTU = \frac{UA_s}{C_{\min}} = \frac{(1.2\text{ kW/m}^2.\text{°C})(7\text{ m}^2)}{5.4\text{ kW/°C}} = 1.556$$

Then the effectiveness of this parallel-flow heat exchanger corresponding to C = 0.646 and NTU=1.556 is determined from

$$\varepsilon = \frac{1-\exp[-NTU(1+C)]}{1+C} = \frac{1-\exp[-1.556(1+0.646)]}{1+0.646} = 0.56$$

Then the actual rate of heat transfer rate becomes

$$\dot{Q} = \varepsilon\dot{Q}_{\max} = (0.56)(486\text{ kW}) = 272.2\text{ kW}$$

Finally, the outlet temperatures of the cold and hot fluid streams are determined to be

$$\dot{Q} = C_c(T_{c,out} - T_{c,in}) \longrightarrow T_{c,out} = T_{c,in} + \frac{\dot{Q}}{C_c} = 20\text{°C} + \frac{272.2\text{ kW}}{5.4\text{ kW/°C}} = \mathbf{70.4°C}$$

$$\dot{Q} = C_h(T_{h,in} - T_{h,out}) \longrightarrow T_{h,out} = T_{h,in} - \frac{\dot{Q}}{C_h} = 110\text{°C} - \frac{272.2\text{ kW}}{8.36\text{ kW/°C}} = \mathbf{77.4°C}$$

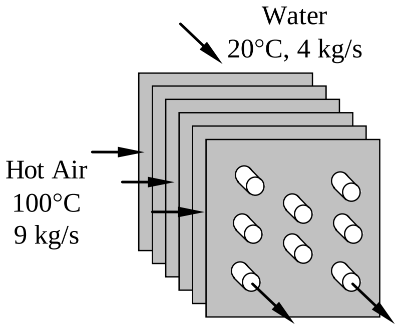
13-89 Water is heated by hot air in a heat exchanger. The mass flow rates and the inlet temperatures are given. The heat transfer surface area of the heat exchanger on the water side is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform.

Properties The specific heats of the water and air are given to be 4.18 and 1.01kJ/kg.°C, respectively.

Analysis The heat capacity rates of the hot and cold fluids are

$$C_h = \dot{m}_h C_{ph} = (4 \text{ kg/s})(4.18 \text{ kJ/kg.°C}) = 16.72 \text{ kW/°C}$$
$$C_c = \dot{m}_c C_{pc} = (9 \text{ kg/s})(1.01 \text{ kJ/kg.°C}) = 9.09 \text{ kW/°C}$$



Therefore, $C_{\min} = C_c = 9.09 \text{ kW/°C}$

and $C = \dfrac{C_{\min}}{C_{\max}} = \dfrac{9.09}{16.72} = 0.544$

Then the NTU of this heat exchanger corresponding to C = 0.544 and ε = 0.65 is determined from Fig. 13-26 to be

NTU = 1.5

Then the surface area of this heat exchanger becomes

$$\text{NTU} = \frac{UA_s}{C_{\min}} \longrightarrow A_s = \frac{\text{NTU}\, C_{\min}}{U} = \frac{(1.5)(9.09 \text{ kW/°C})}{0.260 \text{ kW/m}^2\text{.°C}} = \mathbf{52.4\ m^2}$$

13-90 Water is heated by steam condensing in a condenser. The required length of the tube is to be determined.

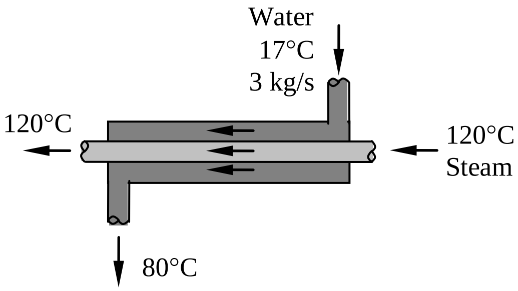
Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform.

Properties The specific heat of the water is given to be 4.18 kJ/kg.°C. The heat of vaporization of water at 120°C is given to be 2203 kJ/kg.

Analysis (*a*) The temperature differences between the steam and the water at the two ends of the condenser are

$$\Delta T_1 = T_{h,in} - T_{c,out} = 120°\text{C} - 80°\text{C} = 40°\text{C}$$

$$\Delta T_2 = T_{h,out} - T_{c,in} = 120°\text{C} - 17°\text{C} = 103°\text{C}$$



The logarithmic mean temperature difference is

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{40 - 103}{\ln(40/103)} = 66.6°\text{C}$$

The rate of heat transfer is determined from

$$\dot{Q} = \dot{m}_c C_{pc}(T_{c,out} - T_{c,in}) = (3\text{ kg/s})(4.18\text{ kJ/kg.°C})(80°\text{C} - 17°\text{C}) = 790.02\text{ kW}$$

The surface area of heat transfer is

$$\dot{Q} = UA_s \Delta T_{lm} \longrightarrow A_s = \frac{\dot{Q}}{U\Delta T_{lm}} = \frac{790.02\text{ kW}}{0.9\text{ kW/m}^2\text{.°C})(66.6°\text{C})} = 13.18\text{ m}^2$$

The length of tube required then becomes

$$A_s = \pi DL \longrightarrow L = \frac{A_s}{\pi D} = \frac{13.18\text{ m}^2}{\pi(0.025\text{ m})} = \mathbf{167.8\text{ m}}$$

(*b*) The rate of heat transfer is

$$\dot{Q} = \dot{m}_c C_{pc}(T_{c,out} - T_{c,in}) = (3\text{ kg/s})(4.18\text{ kJ/kg.°C})(80°\text{C} - 17°\text{C}) = 790.02\text{ kW}$$

and the maximum rate of heat transfer rate is

$$\dot{Q}_{\max} = C_{\min}(T_{h,in} - T_{c,in}) = (12.54\text{ W/°C})(120°\text{C-}17°\text{C}) = 1291.62\text{ kW}$$

Then the effectiveness of this heat exchanger becomes

$$\varepsilon = \frac{Q}{Q_{\max}} = \frac{790.02\text{ kW}}{1291.62\text{ kW}} = 0.61$$

The NTU of this heat exchanger is determined using the relation in Table 13-5 to be

$$\text{NTU} = -\ln(1-\varepsilon) = -\ln(1-0.61) = 0.942$$

The surface area is

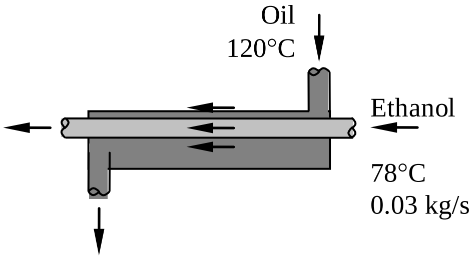
$$NTU = \frac{UA_s}{C_{\min}} \longrightarrow A_s = \frac{NTU\ C_{\min}}{U} = \frac{(0.942)(12.54\text{ kW/°C})}{0.9\text{ kW/m}^2\text{.°C}} = 13.12\text{ m}^2$$

Finally, the length of tube required is

$$A_s = \pi DL \longrightarrow L = \frac{A_s}{\pi D} = \frac{13.12\text{ m}^2}{\pi(0.025\text{ m})} = \mathbf{167\text{ m}}$$

13-91 Ethanol is vaporized by hot oil in a double-pipe parallel-flow heat exchanger. The outlet temperature and the mass flow rate of oil are to be determined using the LMTD and NTU methods.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform.



Properties The specific heat of oil is given to be 2.2 kJ/kg.°C. The heat of vaporization of ethanol at 78°C is given to be 846 kJ/kg.

Analysis (*a*) The rate of heat transfer is

$$\dot{Q} = \dot{m}h_{fg} = (0.03\text{ kg/s})(846\text{ kJ/kg}) = 25.38\text{ kW}$$

The log mean temperature difference is

$$\dot{Q} = UA_s\Delta T_{lm} \longrightarrow \Delta T_{lm} = \frac{\dot{Q}}{UA_s} = \frac{25{,}380\text{ W}}{(320\text{ W/m}^2.°\text{C})(6.2\text{ m}^2)} = 12.8°\text{C}$$

The outlet temperature of the hot fluid can be determined as follows

$$\Delta T_1 = T_{h,in} - T_{c,in} = 120°\text{C} - 78°\text{C} = 42°\text{C}$$

$$\Delta T_2 = T_{h,out} - T_{c,out} = T_{h,out} - 78°\text{C}$$

and $$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{42-(T_{h,out}-78)}{\ln[42/(T_{h,out}-78)]} = 12.8°\text{C}$$

whose solution is $T_{h,out} = \mathbf{79.8°C}$

Then the mass flow rate of the hot oil becomes

$$\dot{Q} = \dot{m}C_p(T_{h,in} - T_{h,out}) \longrightarrow \dot{m} = \frac{\dot{Q}}{C_p(T_{h,in} - T_{h,out})} = \frac{25{,}380\text{ W}}{(2200\text{ J/kg.°C})(120°\text{C} - 79.8°\text{C})} = \mathbf{0.287\text{ kg/s}}$$

(*b*) The heat capacity rate $C = \dot{m}C_p$ of a fluid condensing or evaporating in a heat exchanger is infinity, and thus $C = C_{\min}/C_{\max} = 0$.

The efficiency in this case is determined from $\varepsilon = 1 - e^{-NTU}$

where $$NTU = \frac{UA_s}{C_{\min}} = \frac{(320\text{ W/m}^2.°\text{C})(6.2\text{ m}^2)}{(\dot{m}\text{, kg/s})(2200\text{ J/kg.°C})}$$

and $$\dot{Q}_{\max} = C_{\min}(T_{h,in} - T_{c,in})$$

$$\varepsilon = \frac{Q}{Q_{\max}} = \frac{C_{\min}(T_{h,in} - T_{c,in})}{C_{\min}(T_{h,in} - T_{c,in})} = \frac{120 - T_{h,out}}{120 - 78}$$

$$\dot{Q} = C_h(T_{h,in} - T_{h,out}) = 25{,}380\text{ W}$$

$$\dot{Q} = \dot{m}\times 2200(120 - T_{h,out}) = 25{,}380\text{ W} \quad (1)$$

Also $$\frac{120 - T_{h,out}}{120 - 78} = 1 - e^{-\frac{6.2\times 320}{\dot{m}\times 2200}} \quad (2)$$

Solving (1) and (2) simultaneously gives

$\dot{m}_h = \mathbf{0.287\text{ kg/s}}$ and $T_{h,out} = \mathbf{79.8°C}$

13-92 Water is heated by solar-heated hot air in a heat exchanger. The mass flow rates and the inlet temperatures are given. The outlet temperatures of the water and the air are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform.

Properties The specific heats of the water and air are given to be 4.18 and 1.01 kJ/kg.°C, respectively.

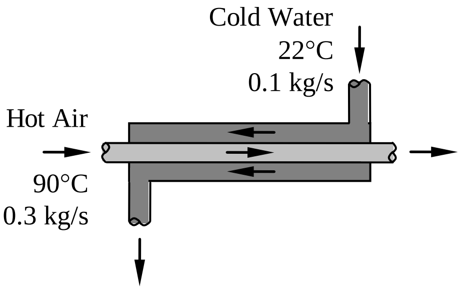
Analysis The heat capacity rates of the hot and cold fluids are

$$C_h = \dot{m}_h C_{ph} = (0.3\text{kg/s})(1010\text{ J/kg.}^\circ\text{C}) = 303\text{ W/}^\circ\text{C}$$
$$C_c = \dot{m}_c C_{pc} = (0.1\text{ kg/s})(4180\text{ J/kg.}^\circ\text{C}) = 418\text{ W/}^\circ\text{C}$$

Therefore, $C_{\min} = C_c = 303\text{ W/}^\circ\text{C}$ and $C = \frac{C_{\min}}{C_{\max}} = \frac{303}{418} = 0.725$

Then the maximum heat transfer rate becomes

$$\dot{Q}_{\max} = C_{\min}(T_{h,in} - T_{c,in})$$
$$= (303\text{ W/°C})(90\text{°C} - 22\text{°C}) = 20{,}604\text{ kW}$$



The heat transfer surface area is

$$A_s = \pi DL = (\pi)(0.012\text{ m})(12\text{ m}) = 0.45\text{ m}^2$$

Then the NTU of this heat exchanger becomes

$$NTU = \frac{UA_s}{C_{\min}} = \frac{(80\text{ W/m}^2.\text{°C})(0.45\text{ m}^2)}{303\text{ W/°C}} = 0.119$$

The effectiveness of this counter-flow heat exchanger corresponding to C = 0.725 and NTU = 0.119 is determined using the relation in Table 13-5 to be

$$\varepsilon = \frac{1-\exp[-NTU(1-C)]}{1-C\exp[-NTU(1-C)]} = \frac{1-\exp[-0.119(1-0.725)]}{1-0.725\exp[-0.119(1-0.725)]} = 0.108$$

Then the actual rate of heat transfer becomes

$$\dot{Q} = \varepsilon\dot{Q}_{\max} = (0.108)(20{,}604\text{ W}) = 2225.2\text{ W}$$

Finally, the outlet temperatures of the cold and hot fluid streams are determined to be

$$\dot{Q} = C_c(T_{c,out} - T_{c,in}) \longrightarrow T_{c,out} = T_{c,in} + \frac{\dot{Q}}{C_c} = 22\text{°C} + \frac{2225.2\text{ W}}{418\text{ W/°C}} = \mathbf{27.3°C}$$
$$\dot{Q} = C_h(T_{h,in} - T_{h,out}) \longrightarrow T_{h,out} = T_{h,in} - \frac{\dot{Q}}{C_h} = 90\text{°C} - \frac{2225.2\text{ W}}{303\text{ W/°C}} = \mathbf{82.7°C}$$

$T_{w,out}$
$T_{air,out}$

13-94E Oil is cooled by water in a double-pipe heat exchanger. The overall heat transfer coefficient of this heat exchanger is to be determined using both the LMTD and NTU methods.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The thickness of the tube is negligible since it is thin-walled.

Properties The specific heats of the water and oil are given to be 1.0 and 0.525 Btu/lbm.°F, respectively.

Analysis (*a*) The rate of heat transfer is

$$\dot{Q} = \dot{m}_h C_{ph}(T_{h,in-}T_{h,out}) = (5\,\text{lbm/s})(0.525\,\text{Btu/lbm.°F})(300-105\text{°F}) = 511.9\,\text{Btu/s}$$

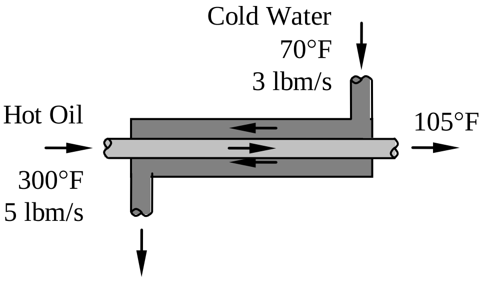
The outlet temperature of the cold fluid is

$$\dot{Q} = \dot{m}_c C_{pc}(T_{c,out}-T_{c,in}) \longrightarrow T_{c,out} = T_{c,in} + \frac{\dot{Q}}{\dot{m}_c C_{pc}} = 70\text{°F} + \frac{511.9\,\text{Btu/s}}{(3\,\text{lbm/s})(1.0\,\text{Btu/lbm.°F})} = 240.6\text{°F}$$

The temperature differences between the two fluids at the two ends of the heat exchanger are

$$\Delta T_1 = T_{h,in} - T_{c,out} = 300\text{° F} - 240.6\text{° F} = 59.4\text{° F}$$

$$\Delta T_2 = T_{h,out} - T_{c,in} = 105\text{° F} - 70\text{° F} = 35\text{° F}$$



The logarithmic mean temperature difference is

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{59.4-35}{\ln(59.4/35)} = 46.1\text{°F}$$

Then the overall heat transfer coefficient becomes

$$\dot{Q} = UA_s\Delta T_{lm} \longrightarrow U = \frac{\dot{Q}}{A_s\Delta T_{lm}} = \frac{511.9\,\text{Btu/s}}{\pi(1/12\,\text{m})(20\,\text{ft})(46.1\text{°F})} = \mathbf{2.12\,Btu/s.ft^2.°F}$$

(*b*) The heat capacity rates of the hot and cold fluids are

$$C_h = \dot{m}_h C_{ph} = (5\text{ lbm/s})(0.525\text{ Btu/lbm.° F}) = 2.625\text{ Btu/s.° F}$$

$$C_c = \dot{m}_c C_{pc} = (3\text{ lbm/s})(1.0\text{ Btu/lbm.° F}) = 3.0\text{ Btu/s.° F}$$

Therefore, $C_{\min} = C_h = 2.625\text{ Btu/s.° F}$ and $C = \dfrac{C_{\min}}{C_{\max}} = \dfrac{2.625}{3.0} = 0.875$

Then the maximum heat transfer rate becomes

$$\dot{Q}_{\max} = C_{\min}(T_{h,in} - T_{c,in}) = (2.625\text{ Btu/s.° F})(300\text{° F - }70\text{° F}) = 603.75\text{ Btu/s}$$

The actual rate of heat transfer and the effectiveness are

$$\dot{Q} = C_h(T_{h,in} - T_{h,out}) = (2.625\text{ Btu/s.° F})(300\text{° F - }105\text{° F}) = 511.9\text{ Btu/s}$$

$$\varepsilon = \frac{\dot{Q}}{\dot{Q}_{\max}} = \frac{511.9}{603.75} = 0.85$$

The NTU of this heat exchanger is determined using the relation in Table 13-3 to be

$$NTU = \frac{1}{C-1}\ln\left(\frac{\varepsilon-1}{\varepsilon C-1}\right) = \frac{1}{0.875-1}\ln\left(\frac{0.85-1}{0.85\times 0.875-1}\right) = 4.28$$

The heat transfer surface area of the heat exchanger is

$$A_s = \pi DL = \pi(1/12\text{ ft})(20\text{ ft}) = 5.24\text{ ft}^2$$

and $$NTU = \frac{UA_s}{C_{\min}} \longrightarrow U = \frac{NTU\ C_{\min}}{A_s} = \frac{(4.28)(2.625\,\text{Btu/s.°F})}{5.24\,\text{ft}^2} = \mathbf{2.14\,Btu/s.ft^2.°F}$$

13-95 Cold water is heated by hot water in a heat exchanger. The net rate of heat transfer and the heat transfer surface area of the heat exchanger are to be determined.

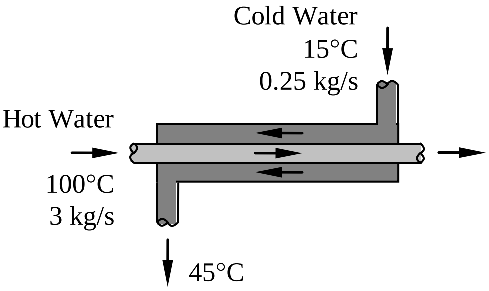
Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform. **5** The thickness of the tube is negligible.

Properties The specific heats of the cold and hot water are given to be 4.18 and 4.19 kJ/kg.°C, respectively.

Analysis The heat capacity rates of the hot and cold fluids are

$$C_h = \dot{m}_h C_{ph} = (0.25\text{ kg/s})(4180\text{ J/kg.°C}) = 1045\text{ W/°C}$$

$$C_c = \dot{m}_c C_{pc} = (3\text{ kg/s})(4190\text{ J/kg.°C}) = 12{,}570\text{ W/°C}$$



Therefore, $C_{\min} = C_c = 1045\text{ W/°C}$

and $C = \dfrac{C_{\min}}{C_{\max}} = \dfrac{1045}{12{,}570} = 0.083$

Then the maximum heat transfer rate becomes

$$\dot{Q}_{\max} = C_{\min}(T_{h,in} - T_{c,in}) = (1045\text{ W/°C})(100\text{°C} - 15\text{°C}) = 88{,}825\text{ W}$$

The actual rate of heat transfer is

$$\dot{Q} = C_h(T_{h,in} - T_{h,out}) = (1045\text{ W/°C})(45\text{°C} - 15\text{°C}) = \mathbf{31{,}350\ W}$$

Then the effectiveness of this heat exchanger becomes

$$\varepsilon = \frac{Q}{Q_{\max}} = \frac{31{,}350}{88{,}825} = 0.35$$

The NTU of this heat exchanger is determined using the relation in Table 13-5 to be

$$NTU = \frac{1}{C-1}\ln\left(\frac{\varepsilon - 1}{\varepsilon C - 1}\right) = \frac{1}{0.083-1}\ln\left(\frac{0.35-1}{0.35\times 0.083-1}\right) = 0.438$$

Then the surface area of the heat exchanger is determined from

$$NTU = \frac{UA}{C_{\min}} \longrightarrow A = \frac{NTU\ C_{\min}}{U} = \frac{(0.438)(1045\text{ W/°C})}{950\text{ W/m}^2\text{.°C}} = \mathbf{0.482\ m^2}$$

13-96

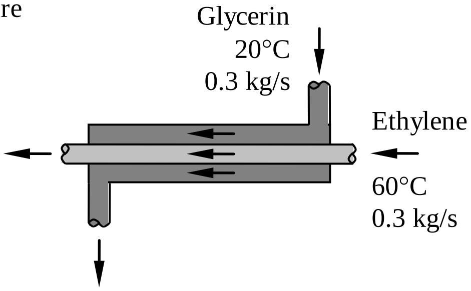
13-97 Glycerin is heated by ethylene glycol in a heat exchanger. Mass flow rates and inlet temperatures are given. The rate of heat transfer and the outlet temperatures are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform. **5** The thickness of the tube is negligible.

Properties The specific heats of the glycerin and ethylene glycol are given to be 2.4 and 2.5 kJ/kg.°C, respectively.

Analysis (*a*) The heat capacity rates of the hot and cold fluids are



$$C_h = \dot{m}_h C_{ph} = (0.3\text{ kg/s})(2400\text{ J/kg.°C}) = 720\text{ W/°C}$$

$$C_c = \dot{m}_c C_{pc} = (0.3\text{ kg/s})(2500\text{ J/kg.°C}) = 750\text{ W/°C}$$

Therefore, $C_{\min} = C_h = 720\text{ W/°C}$

and $C = \dfrac{C_{\min}}{C_{\max}} = \dfrac{720}{750} = 0.96$

Then the maximum heat transfer rate becomes

$$\dot{Q}_{\max} = C_{\min}(T_{h,in} - T_{c,in}) = (720\text{ W/°C})(60\text{°C} - 20\text{°C}) = 28.8\text{ kW}$$

The NTU of this heat exchanger is

$$NTU = \frac{UA_s}{C_{\min}} = \frac{(380\text{ W/m}^2\text{.°C})(5.3\text{ m}^2)}{720\text{ W/°C}} = 2.797$$

Effectiveness of this heat exchanger corresponding to C = 0.96 and NTU = 2.797 is determined using the proper relation in Table 13-4

$$\varepsilon = \frac{1-\exp[-NTU(1+C)]}{1+C} = \frac{1-\exp[-2.797(1+0.96)]}{1+0.96} = 0.508$$

Then the actual rate of heat transfer becomes

$$\dot{Q} = \varepsilon \dot{Q}_{\max} = (0.508)(28.8\text{ kW}) = \mathbf{14.63\text{ kW}}$$

(*b*) Finally, the outlet temperatures of the cold and the hot fluid streams are determined from

$$\dot{Q} = C_c(T_{c,out} - T_{c,in}) \longrightarrow T_{c,out} = T_{c,in} + \frac{\dot{Q}}{C_c} = 20\text{°C} + \frac{14.63\text{ kW}}{0.72\text{ kW/°C}} = \mathbf{40.3°C}$$

$$\dot{Q} = C_h(T_{h,in} - T_{h,out}) \longrightarrow T_{h,out} = T_{h,in} - \frac{\dot{Q}}{C_h} = 60\text{°C} - \frac{14.63\text{ kW}}{0.75\text{ kW/°C}} = \mathbf{40.5°C}$$

13-98 Water is heated by hot air in a cross-flow heat exchanger. Mass flow rates and inlet temperatures are given. The rate of heat transfer and the outlet temperatures are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform. **5** The thickness of the tube is negligible.

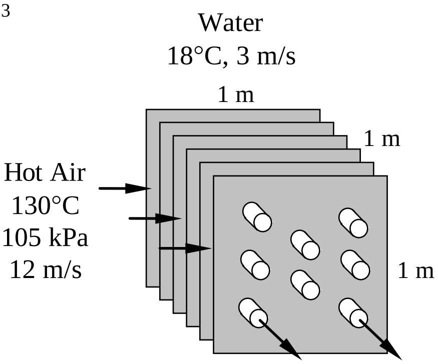
Properties The specific heats of the water and air are given to be 4.18 and 1.01 kJ/kg.°C, respectively.

Analysis The mass flow rates of the hot and the cold fluids are

$$\dot{m}_c = \rho V A_c = (1000\ \text{kg/m}^3)(3\ \text{m/s})[40\pi(0.01\ \text{m})^2/4] = 9.425\ \text{kg/s}$$

$$\rho_{air} = \frac{P}{RT} = \frac{105\ \text{kPa}}{(0.287\ \text{kPa.m}^3/\text{kg.K}) \times (130+273\ \text{K})} = 0.908\ \text{kg/m}^3$$

$$\dot{m}_h = \rho V A_c = (0.908\ \text{kg/m}^3)(12\ \text{m/s})(1\ \text{m})^2 = 10.90\ \text{kg/s}$$



The heat transfer surface area and the heat capacity rates are

$$A_s = n\pi DL = 80\pi(0.01\,\text{m})(1\,\text{m}) = 2.513\,\text{m}^2$$

$$C_h = \dot{m}_h C_{ph} = (9.425\ \text{kg/s})(4.18\ \text{kJ/kg.°C}) = 39.4\ \text{kW/°C}$$

$$C_c = \dot{m}_c C_{pc} = (10.9\ \text{kg/s})(1.010\ \text{kJ/kg.°C}) = 11.01\ \text{kW/°C}$$

Therefore, $C_{\min} = C_c = 11.01\ \text{kW/°C}$ and $C = \dfrac{C_{\min}}{C_{\max}} = \dfrac{11.01}{39.40} = 0.2794$

$$\dot{Q}_{\max} = C_{\min}(T_{h,in} - T_{c,in}) = (11.01\ \text{kW/°C})(30\text{°C} - 18\text{°C}) = 1233\ \text{kW}$$

The NTU of this heat exchanger is

$$NTU = \frac{UA_s}{C_{\min}} = \frac{(130\ \text{W/m}^2.\text{°C})\,(2.513\,\text{m}^2)}{11{,}010\ \text{W/°C}} = 0.02967$$

Noting that this heat exchanger involves mixed cross-flow, the fluid with $C_{\min}$ is mixed, $C_{\max}$ unmixed, effectiveness of this heat exchanger corresponding to C = 0.2794 and NTU =0.02967 is determined using the proper relation in Table 13-4 to be

$$\varepsilon = 1 - \exp\left[-\frac{1}{C}(1 - e^{-CNTU})\right] = 1 - \exp\left[-\frac{1}{0.2794}(1 - e^{-0.2794\times 0.02967})\right] = 0.02912$$

Then the actual rate of heat transfer becomes

$$\dot{Q} = \varepsilon \dot{Q}_{\max} = (0.02912)(1233\,\text{kW}) = \mathbf{35.90\ kW}$$

Finally, the outlet temperatures of the cold and the hot fluid streams are determined from

$$\dot{Q} = C_c(T_{c,out} - T_{c,in}) \longrightarrow T_{c,out} = T_{c,in} + \frac{\dot{Q}}{C_c} = 18\text{°C} + \frac{35.90\ \text{kW}}{39.40\ \text{kW/°C}} = \mathbf{18.9°C}$$

$$\dot{Q} = C_h(T_{h,in} - T_{h,out}) \longrightarrow T_{h,out} = T_{h,in} - \frac{\dot{Q}}{C_h} = 130\text{°C} - \frac{35.90\ \text{kW}}{11.01\,\text{kW/°C}} = \mathbf{126.7°C}$$

13-99 Ethyl alcohol is heated by water in a shell-and-tube heat exchanger. The heat transfer surface area of the heat exchanger is to be determined using both the LMTD and NTU methods.

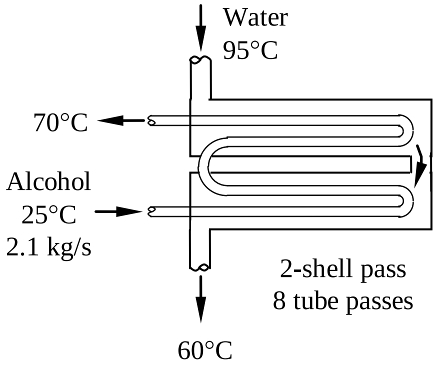
Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform.

Properties The specific heats of the ethyl alcohol and water are given to be 2.67 and 4.19 kJ/kg.°C, respectively.

Analysis (*a*) The temperature differences between the two fluids at the two ends of the heat exchanger are

$$\Delta T_1 = T_{h,in} - T_{c,out} = 95°\text{C} - 70°\text{C} = 25°\text{C}$$

$$\Delta T_2 = T_{h,out} - T_{c,in} = 60°\text{C} - 25°\text{C} = 35°\text{C}$$



The logarithmic mean temperature difference and the correction factor are

$$\Delta T_{lm,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{25-35}{\ln(25/35)} = 29.7°\text{C}$$

$$\left.\begin{aligned} P &= \frac{t_2 - t_1}{T_1 - t_1} = \frac{70-25}{95-25} = 0.64 \\ R &= \frac{T_2 - T_1}{t_1 - t_1} = \frac{95-60}{70-25} = 0.78 \end{aligned}\right\} F = 0.93$$

The rate of heat transfer is determined from

$$\dot{Q} = \dot{m}_c C_{pc}(T_{c,out} - T_{c,in}) = (2.1\text{ kg/s})(2.67\text{ kJ/kg.°C})(70°\text{C} - 25°\text{C}) = 252.3\text{ kW}$$

The surface area of heat transfer is

$$\dot{Q} = UA_s \Delta T_{lm} \longrightarrow A_s = \frac{\dot{Q}}{UF\Delta T_{lm}} = \frac{252.3\text{ kW}}{0.8\text{ kW/m}^2\text{.°C})(0.93)(29.7°\text{C})} = \mathbf{11.4\text{ m}^2}$$

(*b*) The rate of heat transfer is

$$\dot{Q} = \dot{m}_c C_{pc}(T_{c,out} - T_{c,in}) = (2.1\text{ kg/s})(2.67\text{ kJ/kg.°C})(70°\text{C} - 25°\text{C}) = 252.3\text{ kW}$$

The mass flow rate of the hot fluid is

$$\dot{Q} = \dot{m}_h C_{ph}(T_{h,in} - T_{h,out}) \to \dot{m}_h = \frac{\dot{Q}}{C_{ph}(T_{h,in} - T_{h,out})} = \frac{252.3\text{ kW}}{(4.19\text{ kJ/kg.°C})(95°\text{C} - 60°\text{C})} = 1.72\text{ kg/s}$$

The heat capacity rates of the hot and the cold fluids are

$$C_h = \dot{m}_h C_{ph} = (1.72\text{ kg/s})(4.19\text{ kJ/kg.°C}) = 7.21\text{ kW/°C}$$

$$C_c = \dot{m}_c C_{pc} = (2.1\text{ kg/s})(2.67\text{ kJ/kg.°C}) = 5.61\text{ kW/°C}$$

Therefore, $C_{\min} = C_c = 5.61\text{ W/°C}$ and $C = \frac{C_{\min}}{C_{\max}} = \frac{5.61}{7.21} = 0.78$

Then the maximum heat transfer rate becomes

$$\dot{Q}_{\max} = C_{\min}(T_{h,in} - T_{c,in}) = (5.61\text{ W/°C})(95°\text{C} - 25°\text{C}) = 392.7\text{ kW}$$

The effectiveness of this heat exchanger is $\varepsilon = \frac{Q}{Q_{\max}} = \frac{252.3}{392.7} = 0.64$

The NTU of this heat exchanger corresponding to this emissivity and $C = 0.78$ is determined from Fig. 13-26d to be NTU = 1.7. Then the surface area of heat exchanger is determined to be

$$NTU = \frac{UA_s}{C_{\min}} \longrightarrow A_s = \frac{NTU\ C_{\min}}{U} = \frac{(1.7)(5.61\text{ kW/°C})}{0.8\text{ kW/m}^2\text{.°C}} = \mathbf{11.9\text{ m}^2}$$

The small difference between the two results is due to the reading error of the chart.

13-100 Steam is condensed by cooling water in a shell-and-tube heat exchanger. The rate of heat transfer and the rate of condensation of steam are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform. **5** The thickness of the tube is negligible.

Properties The specific heat of the water is given to be 4.18 kJ/kg.°C. The heat of condensation of steam at 30°C is given to be 2430 kJ/kg.

Analysis (*a*) The heat capacity rate of a fluid condensing in a heat exchanger is infinity. Therefore,

$$C_{\min} = C_c = \dot{m}_c C_{pc} = (0.5 \text{ kg/s})(4.18 \text{ kJ/kg.}^\circ\text{C}) = 2.09 \text{ kW/}^\circ\text{C}$$

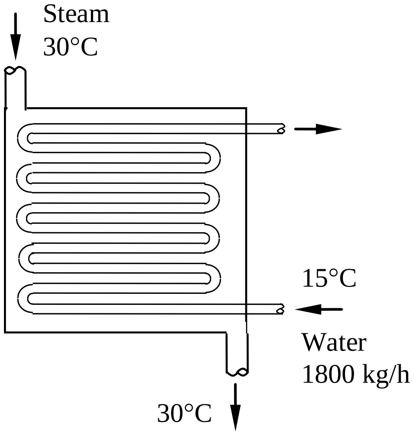
and $C = 0$

Then the maximum heat transfer rate becomes

$$\dot{Q}_{\max} = C_{\min}(T_{h,in} - T_{c,in}) = (2.09 \text{ kW/}^\circ\text{C})(30^\circ\text{C} - 15^\circ\text{C}) = 31.35 \text{ kW}$$

and

$$A_s = 8n\pi DL = 8 \times 50\pi(0.015 \text{ m})(2 \text{ m}) = 37.7 \text{ m}^2$$



The NTU of this heat exchanger

$$NTU = \frac{UA_s}{C_{\min}} = \frac{(3 \text{ kW/m}^2.^\circ\text{C})(37.7 \text{ m}^2)}{2.09 \text{ kW/}^\circ\text{C}} = 54.11$$

Then the effectiveness of this heat exchanger corresponding to $C = 0$ and NTU = 6.76 is determined using the proper relation in Table 13-5

$$\varepsilon = 1 - \exp(-\text{NTU}) = 1 - \exp(-6.76) = 1$$

Then the actual heat transfer rate becomes

$$\dot{Q} = \varepsilon\dot{Q}_{\max} = (1)(31.35 \text{ kW}) = \mathbf{31.35 \text{ kW}}$$

(*b*) Finally, the rate of condensation of the steam is determined from

$$\dot{Q} = \dot{m}h_{fg} \longrightarrow \dot{m} = \frac{\dot{Q}}{h_{fg}} = \frac{31.4 \text{ kJ/s}}{2430 \text{ kJ/kg}} = \mathbf{0.0129 \text{ kg/s}}$$

13-102 Cold water is heated by hot oil in a shell-and-tube heat exchanger. The rate of heat transfer is to be determined using both the LMTD and NTU methods.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform.

Properties The specific heats of the water and oil are given to be 4.18 and 2.2 kJ/kg.°C, respectively.

Analysis (*a*) The LMTD method in this case involves iterations, which involves the following steps:

1) Choose $T_{h,out}$

2) Calculate $\dot{Q}$ from $\dot{Q} = \dot{m}_h C_p (T_{h,out} - T_{h,in})$

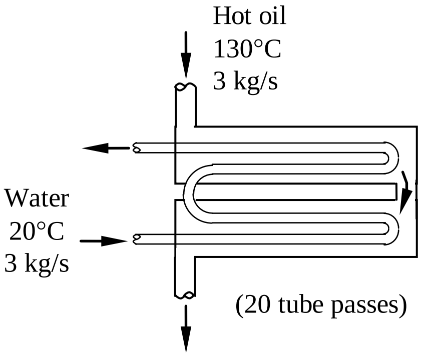
3) Calculate $T_{h,out}$ from $\dot{Q} = \dot{m}_h C_p (T_{h,out} - T_{h,in})$

4) Calculate $\Delta T_{\ln,CF}$

5) Calculate $\dot{Q}$ from $\dot{Q} = UA_s F \Delta T_{\ln,CF}$

6) Compare to the $\dot{Q}$ calculated at step 2, and repeat until reaching the same result

Result: **385 kW**



(*b*) The heat capacity rates of the hot and the cold fluids are

$$C_h = \dot{m}_h C_{ph} = (3 \text{ kg/s})(2.2 \text{ kJ/kg.°C}) = 6.6 \text{ kW/°C}$$
$$C_c = \dot{m}_c C_{pc} = (3 \text{ kg/s})(4.18 \text{ kJ/kg.°C}) = 12.54 \text{ kW/°C}$$

Therefore, $C_{\min} = C_h = 6.6 \text{ kW/°C}$ and $C = \dfrac{C_{\min}}{C_{\max}} = \dfrac{6.6}{12.54} = 0.53$

Then the maximum heat transfer rate becomes

$$\dot{Q}_{\max} = C_{\min}(T_{h,in} - T_{c,in}) = (6.6 \text{ kW/°C})(130\text{°C} - 20\text{°C}) = 726 \text{ kW}$$

The NTU of this heat exchanger is

$$NTU = \frac{UA_s}{C_{\min}} = \frac{(0.3 \text{ kW/m}^2\text{.°C})(20 \text{ m}^2)}{6.6 \text{ kW/°C}} = 0.91$$

Then the effectiveness of this heat exchanger corresponding to C = 0.53 and NTU = 0.91 is determined from Fig. 13-26d to be

$$\varepsilon = 0.53$$

The actual rate of heat transfer then becomes

$$\dot{Q} = \varepsilon \dot{Q}_{\max} = (0.53)(726 \text{ kW}) = \mathbf{385 \text{ kW}}$$

Selection of The Heat Exchangers

13-103C 1) Calculate heat transfer rate, 2) select a suitable type of heat exchanger, 3) select a suitable type of cooling fluid, and its temperature range, 4) calculate or select U, and 5) calculate the size (surface area) of heat exchanger

13-104C The first thing we need to do is determine the life expectancy of the system. Then we need to evaluate how much the larger will save in pumping cost, and compare it to the initial cost difference of the two units. If the larger system saves more than the cost difference in its lifetime, it should be preferred.

13-105C In the case of automotive and aerospace industry, where weight and size considerations are important, and in situations where the space availability is limited, we choose the smaller heat exchanger.

13-106 Oil is to be cooled by water in a heat exchanger. The heat transfer rating of the heat exchanger is to be determined and a suitable type is to be proposed.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible.

Properties The specific heat of the oil is given to be 2.2 kJ/kg.°C.

Analysis The heat transfer rate of this heat exchanger is

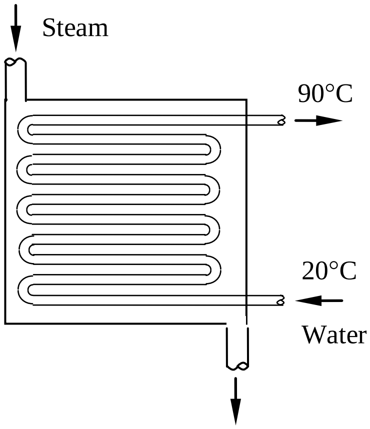
$$\dot{Q} = \dot{m}_c C_{pc}(T_{c,out} - T_{c,in}) = (13\text{ kg/s})(2.2\text{ kJ/kg.°C})(120\text{°C} - 50\text{°C}) = \mathbf{2002\ kW}$$

We propose a compact heat exchanger (like the car radiator) if air cooling is to be used., or a tube-and-shell or plate heat exchanger if water cooling is to be used.

3-107 Water is to be heated by steam in a shell-and-tube process heater. The number of tube passes need to be used is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible.

Properties The specific heat of the water is given to be 4.19 kJ/kg.°C.



Analysis The mass flow rate of the water is

$$\dot{Q}=\dot{m}_c C_{pc}(T_{c,out}-T_{c,in})$$

$$\dot{m}=\frac{\dot{Q}}{C_{pc}(T_{c,out}-T_{c,in})}$$

$$=\frac{600\text{ kW}}{(4.19\text{ kJ/kg.°C})(90°\text{C}-20°\text{C})}$$

$$=2.046\text{ kg/s}$$

The total cross-section area of the tubes corresponding to this mass flow rate is

$$\dot{m}=\rho V A_c \rightarrow A_c=\frac{\dot{m}}{\rho V}=\frac{2.046\text{ kg/s}}{(1000\text{ kg/m}^3)(3\text{ m/s})}=6.82\times10^{-4}\text{ m}^2$$

Then the number of tubes that need to be used becomes

$$A_s=n\frac{\pi D^2}{4}\longrightarrow n=\frac{4A_s}{\pi D^2}=\frac{4(6.82\times10^{-4}\text{ m}^2)}{\pi(0.01\text{ m})^2}=8.68\cong\mathbf{9}$$

Therefore, we need to use at least 9 tubes entering the heat exchanger.

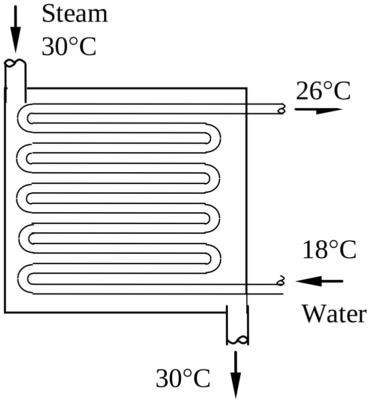
13-109 Cooling water is used to condense the steam in a power plant. The total length of the tubes required in the condenser is to be determined and a suitable HX type is to be proposed.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform.

Properties The specific heat of the water is given to be 4.18 kJ/kg.°C. The heat of condensation of steam at 30°C is given to be 2430 kJ/kg.



Analysis The temperature differences between the steam and the water at the two ends of condenser are

$$\Delta T_1 = T_{h,in} - T_{c,out} = 30°\text{C} - 26°\text{C} = 4°\text{C}$$
$$\Delta T_2 = T_{h,out} - T_{c,in} = 30°\text{C} - 18°\text{C} = 12°\text{C}$$

and the logarithmic mean temperature difference is

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{4-12}{\ln(4/12)} = 7.28°\text{C}$$

The heat transfer surface area is

$$\dot{Q} = UA_s\Delta T_{lm} \longrightarrow A_s = \frac{\dot{Q}}{U\Delta T_{lm}} = \frac{500\times10^6\ \text{W}}{(3500\ \text{W/m}^2.°\text{C})(7.28°\text{C})} = 1.96\times10^4\ \text{m}^2$$

The total length of the tubes required in this condenser then becomes

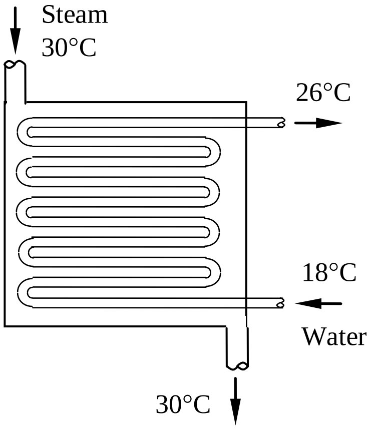
$$A_s = \pi DL \longrightarrow L = \frac{A_s}{\pi D} = \frac{1.96\times10^4\ \text{m}^2}{\pi(0.02\ \text{m})} = 3.123\times10^5\ \text{m} = \mathbf{312.3\ km}$$

A multi-pass shell-and-tube heat exchanger is suitable in this case.

13-110 Cold water is heated by hot water in a heat exchanger. The net rate of heat transfer and the heat transfer surface area of the heat exchanger are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform.

Properties The specific heats of the cold and hot water are given to be 4.18 and 4.19 kJ/kg.°C, respectively.



Analysis The temperature differences between the steam and the water at the two ends of condenser are

$$\Delta T_1 = T_{h,in} - T_{c,out} = 30°\text{C} - 26°\text{C} = 4°\text{C}$$
$$\Delta T_2 = T_{h,out} - T_{c,in} = 30°\text{C} - 18°\text{C} = 12°\text{C}$$

and the logarithmic mean temperature difference is

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{4-12}{\ln(4/12)} = 7.28°\text{C}$$

The heat transfer surface area is

$$\dot{Q} = UA_s \Delta T_{lm} \longrightarrow A_s = \frac{\dot{Q}}{U\Delta T_{lm}} = \frac{300 \times 10^6 \text{ W}}{(3500 \text{ W/m}^2.°\text{C})(7.28°\text{C})} = 1.177 \times 10^4 \text{ m}^2$$

The total length of the tubes required in this condenser then becomes

$$A_s = \pi DL \longrightarrow L = \frac{A_s}{\pi D} = \frac{1.177 \times 10^4 \text{ m}^2}{\pi(0.02 \text{ m})} = 1.874 \times 10^5 \text{ m} = \mathbf{187.4\ km}$$

A multi-pass shell-and-tube heat exchanger is suitable in this case.

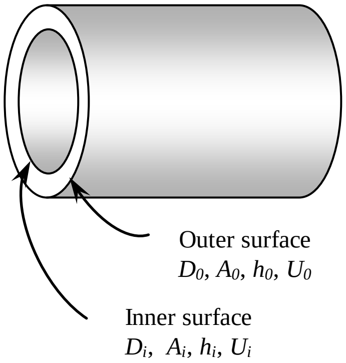
Review Problems

13-111 Hot oil is cooled by water in a multi-pass shell-and-tube heat exchanger. The overall heat transfer coefficient based on the inner surface is to be determined.

Assumptions **1** Water flow is fully developed. **2** Properties of the water are constant.

Properties The properties of water at 300 K ≈25°C are (Table A-9)

$$k = 0.607\ \text{W/m.°C}$$
$$\upsilon = \mu/\rho = 0.894\times10^{-6}\ \text{m}^2\text{/s}$$
$$\text{Pr} = 6.14$$



Analysis The Reynolds number is

$$\text{Re} = \frac{V_m D}{\upsilon} = \frac{(3\ \text{m/s})(0.013\ \text{m})}{0.894\times10^{-6}\ \text{m}^2\text{/s}} = 43{,}771$$

which is greater than 10,000. Therefore, we assume fully developed turbulent flow, and determine Nusselt number from

$$Nu = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.4}\ 0.023(43{,}771)^{0.8}(6.14)^{0.4} = 245$$

and

$$h_i = \frac{k}{D}Nu = \frac{0.607\ \text{W/m.°C}}{0.013\ \text{m}}(245) = 11{,}440\ \text{W/m}^2\text{.°C}$$

The inner and the outer surface areas of the tube are

$$A_i = \pi D_i L = \pi(0.013\ \text{m})(1\ \text{m}) = 0.04084\ \text{m}^2$$
$$A_o = \pi D_o L = \pi(0.015\ \text{m})(1\ \text{m}) = 0.04712\ \text{m}^2$$

The total thermal resistance of this heat exchanger per unit length is

$$\begin{aligned} R &= \frac{1}{h_i A_i} + \frac{\ln(D_o/D_i)}{2\pi k L} + \frac{1}{h_o A_o} \\ &= \frac{1}{(11{,}440\ \text{W/m}^2\text{.°C})(0.04084\ \text{m}^2)} + \frac{\ln(1.5/1.3)}{2\pi(110\ \text{W/m.°C})(1\ \text{m})} + \frac{1}{(35\ \text{W/m}^2\text{.°C})(0.04712\ \text{m}^2)} \\ &= 0.609\text{°C/W} \end{aligned}$$

Then the overall heat transfer coefficient of this heat exchanger based on the inner surface becomes

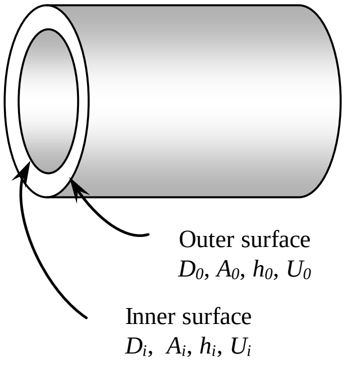
$$R = \frac{1}{U_i A_i} \longrightarrow U_i = \frac{1}{RA_i} = \frac{1}{(0.609\text{°C/W})(0.04084\ \text{m}^2)} = \mathbf{40.2\ W/m^2.°C}$$

13-112 Hot oil is cooled by water in a multi-pass shell-and-tube heat exchanger. The overall heat transfer coefficient based on the inner surface is to be determined.

Assumptions **1** Water flow is fully developed. **2** Properties of the water are constant.

Properties The properties of water at 300 K ≈25°C are (Table A-9)

$$k = 0.607 \text{ W/m.°C}$$
$$\upsilon = \mu / \rho = 0.894 \times 10^{-6} \text{ m}^2\text{/s}$$
$$\Pr = 6.14$$



Analysis The Reynolds number is

$$\text{Re} = \frac{V_m D}{\upsilon} = \frac{(3 \text{ m/s})(0.013 \text{ m})}{0.894 \times 10^{-6} \text{ m}^2\text{/s}} = 43{,}771$$

which is greater than 10,000. Therefore, we assume fully developed turbulent flow, and determine Nusselt number from

$$Nu = 0.023 \text{Re}^{0.8} \Pr^{0.4}\ 0.023(43{,}771)^{0.8}(6.14)^{0.4} = 245$$

and

$$h_i = \frac{k}{D} Nu = \frac{0.607 \text{ W/m.°C}}{0.013 \text{ m}}(245) = 11{,}440 \text{ W/m}^2\text{.°C}$$

The inner and the outer surface areas of the tube are

$$A_i = \pi D_i L = \pi(0.013 \text{ m})(1 \text{ m}) = 0.04084 \text{ m}^2$$
$$A_o = \pi D_o L = \pi(0.015 \text{ m})(1 \text{ m}) = 0.04712 \text{ m}^2$$

The total thermal resistance of this heat exchanger per unit length of it with a fouling factor is

$$\begin{aligned} R &= \frac{1}{h_i A_i} + \frac{\ln(D_o / D_i)}{2\pi kL} + \frac{R_{f,o}}{A_o} + \frac{1}{h_o A_o} \\ &= \frac{1}{(11{,}440 \text{ W/m}^2\text{.°C})(0.04084 \text{ m}^2)} + \frac{\ln(15/13)}{2\pi(110 \text{ W/m.°C})(1 \text{ m})} \\ &\quad + \frac{0.0004 \text{ m}^2\text{.°C/W}}{0.04712 \text{ m}^2} + \frac{1}{(35 \text{ W/m}^2\text{.°C})(0.04712 \text{ m}^2)} \\ &= 0.617\text{°C/W} \end{aligned}$$

Then the overall heat transfer coefficient of this heat exchanger based on the inner surface becomes

$$R = \frac{1}{U_i A_i} \longrightarrow U_i = \frac{1}{RA_i} = \frac{1}{(0.617\text{°C/W})(0.04084 \text{ m}^2)} = \mathbf{39.7 \text{ W/m}^2\text{.°C}}$$

13-113 Water is heated by hot oil in a multi-pass shell-and-tube heat exchanger. The rate of heat transfer and the heat transfer surface area on the outer side of the tube are to be determined. √

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform.

Properties The specific heats of the water and oil are given to be 4.18 and 2.2 kJ/kg.°C, respectively.

Analysis (*a*)The rate of heat transfer in this heat exchanger is

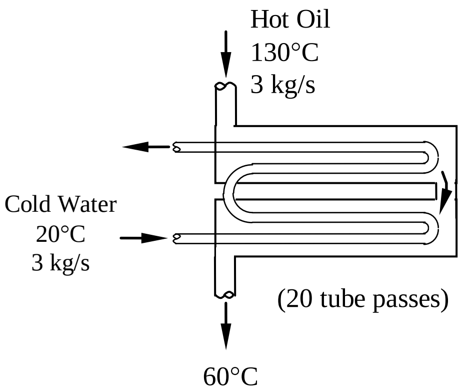
$$\dot{Q} = \dot{m}_h C_{ph}(T_{h,in} - T_{h,out}) = (3\,\text{kg/s})(2.2\,\text{kJ/kg.°C})(130°\text{C} - 60°\text{C}) = \mathbf{462\,kW}$$

(*b*) The outlet temperature of the cold water is

$$\dot{Q} = \dot{m}_c C_{pc}(T_{c,out} - T_{c,in}) \longrightarrow T_{c,out} = T_{c,in} + \frac{\dot{Q}}{\dot{m}_c C_{pc}} = 20°\text{C} + \frac{462\text{ kW}}{(3\text{ kg/s})(4.18\text{ kJ/kg.°C})} = 56.8°\text{C}$$

The temperature differences at the two ends are

$$\Delta T_1 = T_{h,in} - T_{c,out} = 130°\text{C} - 56.8°\text{C} = 73.2°\text{C}$$
$$\Delta T_2 = T_{h,out} - T_{c,in} = 60°\text{C} - 20°\text{C} = 40°\text{C}$$



The logarithmic mean temperature difference is

$$\Delta T_{lm,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{73.2 - 40}{\ln(73.2/40)} = 54.9°\text{C}$$

and

$$\left.\begin{array}{l} P = \dfrac{t_2 - t_1}{T_1 - t_1} = \dfrac{56.8 - 20}{130 - 20} = 0.335 \\ R = \dfrac{T_2 - T_1}{t_2 - t_1} = \dfrac{130 - 60}{56.8 - 20} = 1.90 \end{array}\right\} F = 0.96$$

The heat transfer surface area on the outer side of the tube is then determined from

$$\dot{Q} = UA_s F\Delta T_{lm} \longrightarrow A_s = \frac{\dot{Q}}{UF\Delta T_{lm}} = \frac{462\,\text{kW}}{(0.3\,\text{kW/m}^2.°\text{C})(0.96)(54.9°\text{C})} = \mathbf{29.2\,m^2}$$

13-114E Water is heated by solar-heated hot air in a double-pipe counter-flow heat exchanger. The required length of the tube is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform.

Properties The specific heats of the water and air are given to be 1.0 and 0.24 Btu/lbm.°F, respectively.

Analysis The rate of heat transfer in this heat exchanger is

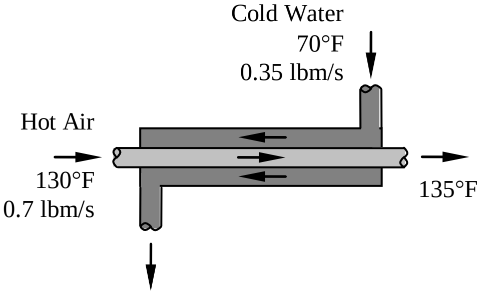
$$\dot{Q} = \dot{m}_h C_{ph}(T_{h,in} - T_{h,out}) = (0.7\text{ lbm/s})(0.24\text{ Btu/lbm.°F})(190\text{°F} - 135\text{°F}) = 9.24\text{ Btu/s}$$

The outlet temperature of the cold water is

$$\dot{Q} = \dot{m}_c C_{pc}(T_{c,out} - T_{c,in}) \longrightarrow T_{c,out} = T_{c,in} + \frac{\dot{Q}}{\dot{m}_c C_{pc}} = 70\text{°F} + \frac{9.24\text{ Btu/s}}{(0.35\text{ lbm/s})(1.0\text{ Btu/lbm.°F})} = 96.4\text{°F}$$

The temperature differences at the two ends are

$$\Delta T_1 = T_{h,in} - T_{c,out} = 190\text{°F} - 96.4\text{°F} = 93.6\text{°F}$$
$$\Delta T_2 = T_{h,out} - T_{c,in} = 135\text{°F} - 70\text{°F} = 65\text{°F}$$



The logarithmic mean temperature difference is

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{93.6 - 65}{\ln(93.6/65)} = 78.43\text{°F}$$

The heat transfer surface area on the outer side of the tube is determined from

$$\dot{Q} = UA_s \Delta T_{lm} \longrightarrow A_s = \frac{\dot{Q}}{U\Delta T_{lm}} = \frac{9.24\text{ Btu/s}}{(20/3600\text{ Btu/s.ft}^2\text{.°F})(78.43\text{°F})} = 21.21\text{ ft}^2$$

Then the length of the tube required becomes

$$A_s = \pi DL \longrightarrow L = \frac{A_s}{\pi D} = \frac{21.21\text{ ft}^2}{\pi(0.5/12\text{ ft})} = \mathbf{162.0\ ft}$$

13-115 It is to be shown that when $\Delta T_1 = \Delta T_2$ for a heat exchanger, the ΔT_{lm} relation reduces to $\Delta T_{\text{lm}} = \Delta T_1 = \Delta T_2$.

Analysis When $\Delta T_1 = \Delta T_2$, we obtain

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{0}{0}$$

This case can be handled by applying L'Hospital's rule (taking derivatives of nominator and denominator separately with respect to ΔT_1 or ΔT_2). That is,

$$\Delta T_{lm} = \frac{d(\Delta T_1 - \Delta T_2)/d\Delta T_1}{d[\ln(\Delta T_1/\Delta T_2)]/d\Delta T_1} = \frac{1}{1/\Delta T_1} = \Delta T_1 = \Delta T_2$$

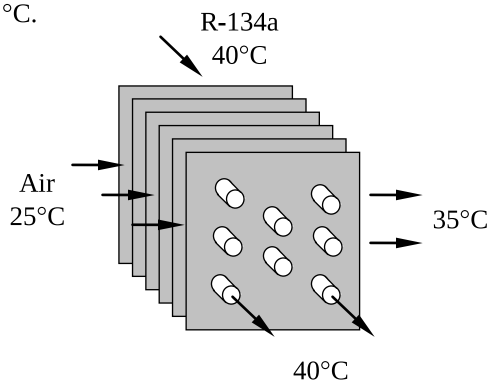
13-116 Refrigerant-134a is condensed by air in the condenser of a room air conditioner. The heat transfer area on the refrigerant side is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform.

Properties The specific heat of air is given to be 1.005 kJ/kg.°C.

Analysis The temperature differences at the two ends are

$$\Delta T_1 = T_{h,in} - T_{c,out} = 40^\circ\text{C} - 35^\circ\text{C} = 5^\circ\text{C}$$
$$\Delta T_2 = T_{h,out} - T_{c,in} = 40^\circ\text{C} - 25^\circ\text{C} = 15^\circ\text{C}$$



The logarithmic mean temperature difference is

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{5-15}{\ln(5/15)} = 9.1^\circ\text{C}$$

The heat transfer surface area on the outer side of the tube is determined from

$$\dot{Q} = UA_s\Delta T_{lm} \longrightarrow A_s = \frac{\dot{Q}}{U\Delta T_{lm}} = \frac{(15{,}000/3600)\text{ kW}}{(0.150\text{ kW/m}^2.^\circ\text{C})(9.1^\circ\text{C})} = \mathbf{3.05\ m^2}$$

13-117 Air is preheated by hot exhaust gases in a cross-flow heat exchanger. The rate of heat transfer is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform.

Properties The specific heats of air and combustion gases are given to be 1.005 and 1.1 kJ/kg.°C, respectively.

Analysis The rate of heat transfer is simply

$$\dot{Q} = [\dot{m}C_p(T_{in} - T_{out})]_{\text{gas.}} = (1.1\text{ kg/s})(1.1\text{ kJ/kg.}^\circ\text{C})(180^\circ\text{C} - 95^\circ\text{C}) = \mathbf{102.9\ kW}$$

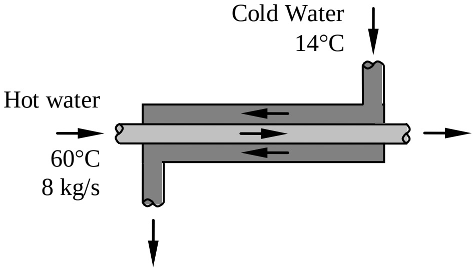
13-118 A water-to-water heat exchanger is proposed to preheat the incoming cold water by the drained hot water in a plant to save energy. The heat transfer rating of the heat exchanger and the amount of money this heat exchanger will save are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible.

Properties The specific heat of the hot water is given to be 4.18 kJ/kg.°C.

Analysis The maximum rate of heat transfer is

$$\begin{aligned}\dot{Q}_{\max} &= \dot{m}_h C_{ph}(T_{h,in} - T_{c,in})\\ &= (8/60\text{ kg/s})(4.18\text{ kJ/kg.°C})(60°\text{C} - 14°\text{C})\\ &= 25.6\text{ kW}\end{aligned}$$



Noting that the heat exchanger will recover 72% of it, the actual heat transfer rate becomes

$$\dot{Q} = \varepsilon \dot{Q}_{\max} = (0.72)(25.6\text{ kJ/s}) = 18.43\text{ kW}$$

which is the heat transfer rating. The operating hours per year are

The annual operating hours = (8 h/day)(5 days/week)(52 week/year) = 2080 h/year

The energy saved during the entire year will be

Energy saved = (heat transfer rate)(operating time)

= (18.43 kJ/s)(2080 h/year)(3600 s/h)

= $1.38\text{x}10^8$ kJ/year

Then amount of fuel and money saved will be

$$\text{Fuel saved} = \frac{\text{Energy saved}}{\text{Furnace efficiency}} = \frac{1.38\times10^8\text{ kJ/year}}{0.78}\left(\frac{1\text{ therm}}{105{,}500\text{ kJ}}\right)$$
$$= 1677\text{ therms/year}$$

Money saved = (fuel saved)(the price of fuel)

= (1677 therms/year)($ 0.54/therm) = **$906/year**

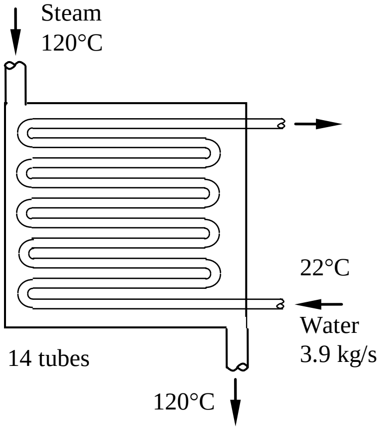
13-119 A shell-and-tube heat exchanger is used to heat water with geothermal steam condensing. The rate of heat transfer, the rate of condensation of steam, and the overall heat transfer coefficient are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** Fluid properties are constant.

Properties The heat of vaporization of geothermal water at 120°C is given to be h_{fg} = 2203 kJ/kg and specific heat of water is given to be C_p = 4180 J/kg.°C.

Analysis (*a*) The outlet temperature of the water is

$$T_{c,out} = T_{h,out} - 46 = 120°C - 46°C = 74°C$$



Then the rate of heat transfer becomes

$$\begin{aligned}\dot{Q} &= [\dot{m}C_p(T_{out} - T_{in})]_{water}\\ &= (3.9\text{ kg/s})(4.18\text{ kJ/kg.°C})(74°C - 22°C)\\ &= \mathbf{847.7\text{ kW}}\end{aligned}$$

(*b*) The rate of condensation of steam is determined from

$$\dot{Q} = (\dot{m}h_{fg})_{\substack{\text{geothermal}\\ \text{steam}}}$$

$$847.7\text{ kW} = \dot{m}(2203\text{ kJ/kg}) \longrightarrow \dot{m} = \mathbf{0.385\text{ kg/s}}$$

(*c*) The heat transfer area is

$$A_i = n\pi D_i L = 14\pi(0.024\text{ m})(3.2\text{ m}) = 3.378\text{ m}^2$$

The logarithmic mean temperature difference for counter-flow arrangement and the correction factor F are

$$\Delta T_1 = T_{h,in} - T_{c,out} = 120°C - 74°C = 46°C$$
$$\Delta T_2 = T_{h,out} - T_{c,in} = 120°C - 22°C = 98°C$$

$$\Delta T_{lm,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)} = \frac{46-98}{\ln(46/98)} = 68.8°C$$

$$\left.\begin{aligned}P &= \frac{t_2 - t_1}{T_1 - t_1} = \frac{74-22}{120-22} = 0.53\\ R &= \frac{T_1 - T_2}{t_2 - t_1} = \frac{120-120}{74-22} = 0\end{aligned}\right\} F = 1$$

Then the overall heat transfer coefficient is determined to be

$$\dot{Q} = U_i A_i F\Delta T_{lm,CF} \longrightarrow U_i = \frac{\dot{Q}}{A_i F\Delta T_{lm,CF}} = \frac{847{,}700\text{ W}}{(3.378\text{ m}^2)(1)(68.8°C)} = \mathbf{3648\text{ W/m}^2.°C}$$

13-120 Water is heated by geothermal water in a double-pipe counter-flow heat exchanger. The mass flow rate of the geothermal water and the outlet temperatures of both fluids are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform.

Properties The specific heats of the geothermal water and the cold water are given to be 4.25 and 4.18 kJ/kg.°C, respectively.

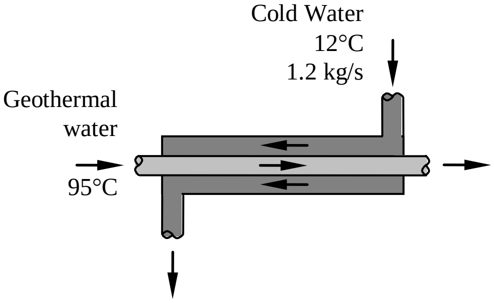
Analysis The heat capacity rates of the hot and cold fluids are

$$C_h = \dot{m}_h C_{ph} = \dot{m}_h(4.25\text{ kJ/kg.°C}) = 4.25\dot{m}_h$$

$$C_c = \dot{m}_c C_{pc} = (1.2\text{ kg/s})(4.18\text{ kJ/kg.°C}) = 5.016\text{ kW/°C}$$

$$C_{\min} = C_c = 5.016\text{ kW/°C}$$

and $$C = \frac{C_{\min}}{C_{\max}} = \frac{5.016}{4.25\dot{m}_h} = \frac{1.1802}{\dot{m}_h}$$



The NTU of this heat exchanger is

$$NTU = \frac{UA_s}{C_{\min}} = \frac{(0.480\text{ kW/m}^2.\text{°C})(25\text{ m}^2)}{5.016\text{ kW/°C}} = 2.392$$

Using the effectiveness relation, we find the capacity ratio

$$\varepsilon = \frac{1-\exp[-\text{NTU}(1-C)]}{1-C\exp[-\text{NTU}(1-C)]} \longrightarrow 0.823 = \frac{1-\exp[-2.392(1-C)]}{1-C\exp[-2.392(1-C)]} \longrightarrow C = 0.494$$

Then the mass flow rate of geothermal water is determined from

$$C = \frac{1.1802}{\dot{m}_h} \longrightarrow 0.494 = \frac{1.1802}{\dot{m}_h} \longrightarrow \dot{m}_h = \mathbf{2.39\text{ kg/s}}$$

The maximum heat transfer rate is

$$\dot{Q}_{\max} = C_{\min}(T_{\text{h,in}} - T_{\text{c,in}}) = (5.016\text{ kW/°C})(95\text{°C} - 12\text{°C}) = 416.328\text{ kW}$$

Then the actual rate of heat transfer rate becomes

$$\dot{Q} = \varepsilon \dot{Q}_{\max} = (0.823)(416.328\text{ kW}) = 342.64\text{ kW}$$

The outlet temperatures of the geothermal and cold waters are determined to be

$$\dot{Q} = C_c(T_{\text{c,out}} - T_{\text{c,in}}) \longrightarrow 342.64\text{ kW} = (5.016\text{ kW/°C})(T_{\text{c,out}} - 12) \longrightarrow T_{\text{c,out}} = \mathbf{80.3°C}$$

$$\dot{Q} = \dot{m}_h C_{ph}(T_{\text{h,in}} - T_{\text{h,out}})$$

$$342.64\text{ kW} = (2.39\text{ kg/s})(4.25\text{ kJ/kg.°C})(95 - T_{\text{h,out}}) \longrightarrow T_{\text{h,out}} = \mathbf{61.3°C}$$

13-121 Air is to be heated by hot oil in a cross-flow heat exchanger with both fluids unmixed. The effectiveness of the heat exchanger, the mass flow rate of the cold fluid, and the rate of heat transfer are to be determined.

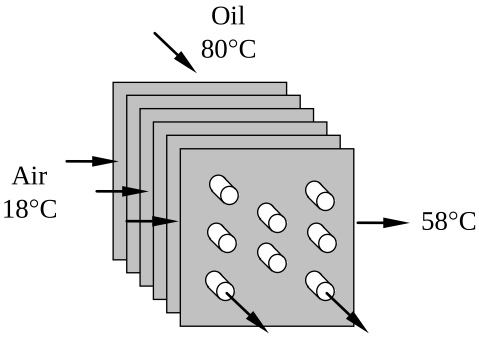
.***Assumptions*** **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform.

Properties The specific heats of the air and the oil are given to be 1.006 and 2.15 kJ/kg.°C, respectively.

Analysis (*a*) The heat capacity rates of the hot and cold fluids are

$$C_h = \dot{m}_h C_{ph} = 0.5\dot{m}_c (2.15\ \text{kJ/kg.°C}) = 1.075\dot{m}_c$$

$$C_c = \dot{m}_c C_{pc} = \dot{m}_c (1.006\ \text{kJ/kg.°C}) = 1.006\dot{m}_c$$



Therefore, $C_{\min} = C_c = 1.006\dot{m}_c$

and $C = \dfrac{C_{\min}}{C_{\max}} = \dfrac{1.006\dot{m}_c}{1.075\dot{m}_c} = 0.936$

The effectiveness of the heat exchanger is determined from

$$\varepsilon = \frac{\dot{Q}}{\dot{Q}_{\max}} = \frac{C_c (T_{\text{c,out}} - T_{\text{c,in}})}{C_c (T_{\text{h,in}} - T_{\text{c,in}})} = \frac{58-18}{80-18} = \mathbf{0.645}$$

(*b*) The NTU of this heat exchanger is expressed as

$$NTU = \frac{UA_s}{C_{\min}} = \frac{(0.750\ \text{kW/°C})}{1.006\dot{m}_c} = \frac{0.7455}{\dot{m}_c}$$

The NTU of this heat exchanger can also be determined from

$$NTU = -\frac{\ln[C\ln(1-\varepsilon)+1]}{C} = -\frac{\ln[0.936\times\ln(1-0.645)+1]}{0.936} = 3.724$$

Then the mass flow rate of the air is determined to be

$$\text{NTU} = \frac{UA_s}{C_{\min}} \longrightarrow 3.724 = \frac{(0.750\ \text{kW/°C})}{1.006\dot{m}_c} \longrightarrow \dot{m}_c = \mathbf{0.20\ kg/s}$$

(*c*) The rate of heat transfer is determined from

$$\dot{Q} = \dot{m}_c C_{pc} (T_{\text{c,out}} - T_{\text{c,in}}) = (0.20\ \text{kg/s})(1.006\ \text{kJ/kg.°C})(58\text{-}18)\text{°C} = \mathbf{8.05\ kW}$$

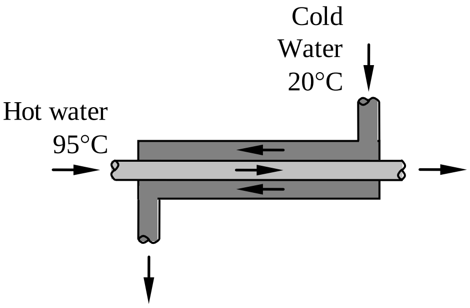
13-122 A water-to-water counter-flow heat exchanger is considered. The outlet temperature of the cold water, the effectiveness of the heat exchanger, the mass flow rate of the cold water, and the heat transfer rate are to be determined.

.***Assumptions*** **1** Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** The overall heat transfer coefficient is constant and uniform.

Properties The specific heats of both the cold and the hot water are given to be 4.18 kJ/kg.°C.

Analysis (*a*) The heat capacity rates of the hot and cold fluids are

$$C_h = \dot m_h C_{ph} = 1.5\dot m_c(4.18\ \text{kJ/kg.°C}) = 6.27\dot m_c$$
$$C_c = \dot m_c C_{pc} = \dot m_c(4.18\ \text{kJ/kg.°C}) = 4.18\dot m_c$$



Therefore, $C_{\min} = C_c = 4.18\dot m_c$

and $C = \dfrac{C_{\min}}{C_{\max}} = \dfrac{4.18\dot m_c}{6.27\dot m_c} = 0.667$

The rate of heat transfer can be expressed as

$$\dot Q = C_c(T_{\text{c,out}} - T_{\text{c,in}}) = (4.18\dot m_c)(T_{\text{c,out}} - 20)$$
$$\dot Q = C_h(T_{\text{h,in}} - T_{\text{h,out}}) = (6.27\dot m_c)\left[95-(T_{\text{c,out}}+15)\right] = (6.27\dot m_c)(80-T_{\text{c,out}})$$

Setting the above two equations equal to each other we obtain the outlet temperature of the cold water

$$\dot Q = 4.18\dot m_c(T_{\text{c,out}} - 20) = 6.27\dot m_c(80 - T_{\text{c,out}}) \longrightarrow T_{\text{c,out}} = \mathbf{56°C}$$

(*b*) The effectiveness of the heat exchanger is determined from

$$\varepsilon = \frac{\dot Q}{\dot Q_{\max}} = \frac{C_c(T_{\text{c,out}} - T_{\text{c,in}})}{C_c(T_{\text{h,in}} - T_{\text{c,in}})} = \frac{4.18\dot m_c(56-20)}{4.18\dot m_c(95-20)} = \mathbf{0.48}$$

(*c*) The NTU of this heat exchanger is determined from

$$NTU = \frac{1}{C-1}\ln\left(\frac{\varepsilon-1}{\varepsilon C-1}\right) = \frac{1}{0.667-1}\ln\left(\frac{0.48-1}{0.48\times0.667-1}\right) = 0.805$$

Then, from the definition of NTU, we obtain the mass flow rate of the cold fluid:

$$NTU = \frac{UA_s}{C_{\min}} \longrightarrow 0.805 = \frac{1.400\ \text{kW/°C}}{4.18\dot m_c} \longrightarrow \dot m_c = \mathbf{0.416\ kg/s}$$

(*d*) The rate of heat transfer is determined from

$$\dot Q = \dot m_c C_{pc}(T_{\text{c,out}} - T_{\text{c,in}}) = (0.416\ \text{kg/s})(4.18\ \text{kJ/kg.°C})(56-20)\text{°C} = \mathbf{62.6\ kW}$$

Chapter 14
MASS TRANSFER

Mass Transfer and Analogy Between Heat and Mass Transfer

14-1C *Bulk fluid flow* refers to the transportation of a fluid on a macroscopic level from one location to another in a flow section by a mover such as a fan or a pump. *Mass flow* requires the presence of two regions at different chemical compositions, and it refers to the movement of a chemical species from a high concentration region towards a lower concentration one relative to the other chemical species present in the medium. Mass transfer cannot occur in a homogeneous medium.

14-2C The *concentration* of a commodity is defined as the amount of that commodity per unit volume. The *concentration gradient dC/dx* is defined as the change in the concentration C of a commodity per unit length in the direction of flow x. The *diffusion rate* of the commodity is expressed as

$$\dot{Q} = -k_{\text{diff}} A \frac{dC}{dx}$$

where A is the area normal to the direction of flow and k_{diff} is the *diffusion coefficient* of the medium, which is a measure of how fast a commodity diffuses in the medium.

14-3C Examples of different kinds of diffusion processes:

(a) *Liquid-to-gas*: A gallon of gasoline left in an open area will eventually evaporate and diffuse into air.

(b) *Solid-to-liquid*: A spoon of sugar in a cup of tea will eventually dissolve and move up.

(c) *Solid-to gas*: A moth ball left in a closet will sublimate and diffuse into the air.

(d) *Gas-to-liquid*: Air dissolves in water.

14-4C Although heat and mass can be converted to each other, there is no such a thing as “mass radiation”, and mass transfer cannot be studied using the laws of radiation transfer. Mass transfer is analogous to conduction, but it is not analogous to radiation.

14-5C (*a*) *Temperature difference* is the driving force for heat transfer, (*b*) *voltage difference* is the driving force for electric current flow, and (*c*) *concentration difference* is the driving force for mass transfer.

14-6C (*a*) *Homogenous reactions* in mass transfer represent the generation of a species within the medium. Such reactions are analogous to internal heat generation in heat transfer. (*b*) *Heterogeneous reactions* in mass transfer represent the generation of a species at the surface as a result of chemical reactions occurring at the surface. Such reactions are analogous to specified surface heat flux in heat transfer.

Mass Diffusion

14-7C In the relation $\dot{Q} = -kA(dT/dx)$, the quantities $\dot{Q}$, k, A, and T represent the following in heat conduction and mass diffusion:

$\dot{Q}$ = Rate of heat transfer in heat conduction, and rate of mass transfer in mass diffusion.

k = Thermal conductivity in heat conduction, and mass diffusivity in mass diffusion.

A = Area normal to the direction of flow in both heat and mass transfer.

T = Temperature in heat conduction, and concentration in mass diffusion.

14-8C (*a*) T (*b*) F (*c*) F (*d*) T (*e*) F

14-9C (*a*) T (*b*) F (*c*) F (*d*) T (*e*) T

14-10C In the Fick's law of diffusion relations expressed as $\dot{m}_{\text{diff,A}} = -\rho A D_{\text{AB}} \dfrac{dw_{\text{A}}}{dx}$ and $\dot{N}_{\text{diff,A}} = -CAD_{\text{AB}} \dfrac{dy_{\text{A}}}{dx}$, the diffusion coefficients D_{AB} are the same.

14-11C The mass diffusivity of a gas mixture (*a*) increases with increasing temperature and (*a*) decreases with increasing pressure.

14-12C In a binary ideal gas mixture of species A and B, the diffusion coefficient of A in B is equal to the diffusion coefficient of B in A. Therefore, the mass diffusivity of air in water vapor will be equal to the mass diffusivity of water vapor in air since the air and water vapor mixture can be treated as ideal gases.

14-13C Solids, in general, have different diffusivities in each other. At a given temperature and pressure, the mass diffusivity of copper in aluminum will not be the equal to the mass diffusivity of aluminum in copper.

14-14C We would carry out the hardening process of steel by carbon at high temperature since mass diffusivity increases with temperature, and thus the hardening process will be completed in a short time.

14-15C The molecular weights of CO_2 and N_2O gases are the same (both are 44). Therefore, the mass and mole fractions of each of these two gases in a gas mixture will be the same.

14-16 The molar fractions of the constituents of moist air are given. The mass fractions of the constituents are to be determined.

Assumptions The small amounts of gases in air are ignored, and dry air is assumed to consist of N_2 and O_2 only.

Properties The molar masses of N_2, O_2, and H_2O are 28.0, 32.0, and 18.0 kg/kmol, respectively (Table A-1)

Analysis The molar mass of moist air is determined to be

$$M = \sum y_i M_i = 0.78 \times 28.0 + 0.20 \times 32.0 + 0.02 \times 18 = 28.6 \text{ kg / kmol}$$

Then the mass fractions of constituent gases are determined from Eq. 14-10 to be

Moist air
78% N_2
20% O_2
2% H_2 O
(Mole fractions)

$$\text{N}_2\text{:} \qquad w_{\text{N}_2} = y_{\text{N}_2} \frac{M_{\text{N}_2}}{M} = (0.78)\frac{28.0}{28.6} = \mathbf{0.764}$$

$$\text{O}_2\text{:} \qquad w_{\text{O}_2} = y_{\text{O}_2} \frac{M_{\text{O}_2}}{M} = (0.20)\frac{32.0}{28.6} = \mathbf{0.224}$$

$$\text{H}_2\text{O:} \qquad w_{\text{H}_2\text{O}} = y_{\text{H}_2\text{O}} \frac{M_{\text{H}_2\text{O}}}{M} = (0.02)\frac{18.0}{28.6} = \mathbf{0.012}$$

Therefore, the mass fractions of N_2, O_2, and H_2O in dry air are 76.4%, 22.4%, and 1.2%, respectively.

14-17E The masses of the constituents of a gas mixture are given. The mass fractions, mole fractions, and the molar mass of the mixture are to be determined.

Assumptions None.

Properties The molar masses of N_2, O_2, and CO_2 are 28, 32, and 44 lbm/lbmol, respectively (Table A-1)

Analysis (*a*) The total mass of the gas mixture is determined to be

$$m = \sum m_i = m_{\mathrm{O_2}} + m_{\mathrm{N_2}} + m_{\mathrm{CO_2}} = 5 + 8 + 10 = 23\ \mathrm{lbm}$$

Then the mass fractions of constituent gases are determined to be

5 lbm O_2
8 lbm N_2
10 lbm CO_2

N_2: $$w_{\mathrm{N_2}} = \frac{m_{\mathrm{N_2}}}{m} = \frac{8}{23} = \mathbf{0.348}$$

O_2: $$w_{\mathrm{O_2}} = \frac{m_{\mathrm{O_2}}}{m} = \frac{5}{23} = \mathbf{0.217}$$

CO_2: $$w_{\mathrm{CO_2}} = \frac{m_{\mathrm{CO_2}}}{m} = \frac{10}{23} = \mathbf{0.435}$$

(*b*) To find the mole fractions, we need to determine the mole numbers of each component first,

N_2: $$N_{\mathrm{N_2}} = \frac{m_{\mathrm{N_2}}}{M_{\mathrm{N_2}}} = \frac{8\ \mathrm{lbm}}{28\ \mathrm{lbm/lbmol}} = \mathbf{0.286\ lbmol}$$

O_2: $$N_{\mathrm{O_2}} = \frac{m_{\mathrm{O_2}}}{M_{\mathrm{O_2}}} = \frac{5\ \mathrm{lbm}}{32\ \mathrm{lbm/lbmol}} = \mathbf{0.156\ lbmol}$$

CO_2: $$N_{\mathrm{CO_2}} = \frac{m_{\mathrm{CO_2}}}{M_{\mathrm{CO_2}}} = \frac{10\ \mathrm{lbm}}{44\ \mathrm{lbm/lbmol}} = \mathbf{0.227\ lbmol}$$

Thus,

$$N_m = \sum N_i = N_{\mathrm{N_2}} + N_{\mathrm{O_2}} + N_{\mathrm{CO_2}} = 0.286 + 0.156 + 0.227 = 0.669\ \mathrm{lbmol}$$

Then the mole fraction of gases are determined to be

N_2: $$y_{\mathrm{N_2}} = \frac{N_{\mathrm{N_2}}}{N_m} = \frac{0.2868}{0.669} = \mathbf{0.428}$$

O_2: $$y_{\mathrm{O_2}} = \frac{N_{\mathrm{O_2}}}{N_m} = \frac{0.156}{0.669} = \mathbf{0.233}$$

CO_2: $$y_{\mathrm{CO_2}} = \frac{N_{\mathrm{CO_2}}}{N_m} = \frac{0.227}{0.669} = \mathbf{0.339}$$

(*c*) The molar mass of the mixture is determined from

$$M = \frac{m_m}{N_m} = \frac{23\ \mathrm{lbm}}{0.669\ \mathrm{lbmol}} = \mathbf{34.4\ lbm/lbmol}$$

14-18 The mole fractions of the constituents of a gas mixture are given. The mass of each gas and the molar mass of the mixture are to be determined.

Assumptions None.

Properties The molar masses of H_2 and N_2 are 2.0 and 28.0 kg/kmol, respectively (Table A-1)

Analysis The mass of each gas is

$$\mathrm{H_2}: \quad m_{\mathrm{H_2}} = N_{\mathrm{H_2}} M_{\mathrm{H_2}} = (8\ \mathrm{kmol}) \times (2\ \mathrm{kg/kmol}) = \mathbf{16\ \ kg}$$

$$\mathrm{N_2}: \quad m_{\mathrm{N_2}} = N_{\mathrm{N_2}} M_{\mathrm{N_2}} = 2\ \mathrm{kmol}) \times (28\ \mathrm{kg/kmol}) = \mathbf{56\ \ kg}$$

8 kmol H_2
2 kmol N_2

The molar mass of the mixture and its apparent gas constant are determined to be

$$M = \frac{m_m}{N_m} = \frac{16+56\ \mathrm{kg}}{8+2\ \mathrm{kmol}} = 7.2\ \ \mathrm{kg/kmol}$$

$$R = \frac{R_u}{M} = \frac{8.314\ \mathrm{kJ/kmol \cdot K}}{7.2\ \mathrm{kg/kmol}} = \mathbf{1.15\ \ kJ/kg \cdot K}$$

14-19 The mole numbers of the constituents of a gas mixture at a specified pressure and temperature are given. The mass fractions and the partial pressures of the constituents are to be determined.

Assumptions The gases behave as ideal gases.

Properties The molar masses of N_2, O_2 and CO_2 are 28, 32, and 44 kg/kmol, respectively (Table A-1)

Analysis When the mole fractions of a gas mixture are known, the mass fractions can be determined from

$$w_i = \frac{m_i}{m_m} = \frac{N_i M_i}{N_m M_m} = y_i \frac{M_i}{M_m}$$

The apparent molar mass of the mixture is

$$M = \sum y_i M_i = 0.65 \times 28.0 + 0.20 \times 32.0 + 0.15 \times 44.0 = 31.2\ \ \mathrm{kg/kmol}$$

Then the mass fractions of the gases are determined from

$$\mathrm{N_2}: \quad w_{\mathrm{N_2}} = y_{\mathrm{N_2}} \frac{M_{\mathrm{N_2}}}{M} = (0.65)\frac{28.0}{31.2} = \mathbf{0.583} \quad \text{(or 58.3\%)}$$

$$\mathrm{O_2}: \quad w_{\mathrm{O_2}} = y_{\mathrm{O_2}} \frac{M_{\mathrm{O_2}}}{M} = (0.20)\frac{32.0}{31.2} = \mathbf{0.205} \quad \text{(or 20.5\%)}$$

$$\mathrm{CO_2}: \quad w_{\mathrm{CO_2}} = y_{\mathrm{CO_2}} \frac{M_{\mathrm{CO_2}}}{M_m} = (0.15)\frac{44}{31.2} = \mathbf{0.212} \quad \text{(or 21.2\%)}$$

65% N_2
20% O_2
15% CO_2

290 K
250 kPa

Noting that the total pressure of the mixture is 250 kPa and the pressure fractions in an ideal gas mixture are equal to the mole fractions, the partial pressures of the individual gases become

$$P_{\mathrm{N_2}} = y_{\mathrm{N_2}} P = (0.65)(250\ \mathrm{kPa}) = \mathbf{162.5\ kPa}$$

$$P_{\mathrm{O_2}} = y_{\mathrm{O_2}} P = (0.20)(250\ \mathrm{kPa}) = \mathbf{50\ kPa}$$

$$P_{\mathrm{CO_2}} = y_{\mathrm{CO_2}} P = (0.15)(250\ \mathrm{kPa}) = \mathbf{37.5\ kPa}$$

14-20 The binary diffusion coefficients of CO_2 in air at various temperatures and pressures are to be determined.

Assumptions The mixture is sufficiently dilute so that the diffusion coefficient is independent of mixture composition.

Properties The binary diffusion coefficients of CO_2 in air at 1 atm pressure are given in Table 14-1 to be 0.74×10^{-5}, 2.63×10^{-5}, and 5.37×10^{-5} m^2/s at temperatures of 200 K, 400 K, and 600 K, respectively.

Analysis Noting that the binary diffusion coefficients of gases are inversely proportional to pressure, the diffusion coefficients at given pressures are determined from

$$D_{AB}(T,P) = D_{AB}(T,\ 1\text{ atm})\ /\ P$$

where P is in atm.

(*a*) At 200 K and 1 atm: D_{AB} (200 K, 1 atm) $=$ **0.74×10^{-5} m^2/s** (since P = 1 atm).

(*b*) At 400 K and 0.8 atm: D_{AB}(400 K, 0.8 atm)=D_{AB}(400 K, 1 atm)/0.8=(2.63×10^{-5})/0.8 = **3.29×10^{-5} m^2/s**

(*c*) At 600 K and 3 atm: D_{AB}(600 K, 3 atm)=D_{AB}(600 K, 1 atm)/3=(5.37×10^{-5})/3 = **1.79×10^{-5} m^2/s**

14-21 The binary diffusion coefficient of O_2 in N_2 at various temperature and pressures are to be determined.

Assumptions The mixture is sufficiently dilute so that the diffusion coefficient is independent of mixture composition.

Properties The binary diffusion coefficient of O_2 in N_2 at T_1 = 273 K and P_1 = 1 atm is given in Table 14-2 to be 1.8×10^{-5} m^2/s.

Analysis Noting that the binary diffusion coefficient of gases is proportional to 3/2 power of temperature and inversely proportional to pressure, the diffusion coefficients at other pressures and temperatures can be determined from

$$\frac{D_{\text{AB},1}}{D_{\text{AB},2}} = \frac{P_2}{P_1}\left(\frac{T_1}{T_2}\right)^{3/2} \quad \rightarrow \ D_{\text{AB},2} = D_{\text{AB},1}\frac{P_1}{P_2}\left(\frac{T_2}{T_1}\right)^{3/2}$$

(*a*) At 200 K and 1 atm: $D_{\text{AB},2} = (1.8\times10^{-5}\ \text{m}^2/\text{s})\dfrac{1\,\text{atm}}{1\,\text{atm}}\left(\dfrac{200\,\text{K}}{273\,\text{K}}\right)^{3/2} = \mathbf{1.13\times10^{-5}\ m^2/s}$

(*b*) At 400 K and 0.8 atm: $D_{\text{AB},2} = (1.8\times10^{-5}\ \text{m}^2/\text{s})\dfrac{1\,\text{atm}}{0.8\,\text{atm}}\left(\dfrac{400\,\text{K}}{273\,\text{K}}\right)^{3/2} = \mathbf{4.0\times10^{-5}\ m^2/s}$

(*c*) At 600 K and 3 atm: $D_{\text{AB},2} = (1.8\times10^{-5}\ \text{m}^2/\text{s})\dfrac{1\,\text{atm}}{3\,\text{atm}}\left(\dfrac{600\,\text{K}}{273\,\text{K}}\right)^{3/2} = \mathbf{1.95\times10^{-5}\ m^2/s}$

14-22E The error involved in assuming the density of air to remain constant during a humidification process is to be determined.

Properties The density of moist air before and after the humidification process is determined from the psychrometric chart to be

$$\left.\begin{array}{l} T_1 = 80^\circ\text{F} \\ \phi_1 = 30\% \end{array}\right\} \rho_{air,1} = 0.0727 \text{lbm/ft}^3 \qquad \text{and} \qquad \left.\begin{array}{l} T_1 = 80^\circ\text{F} \\ \phi_1 = 90\% \end{array}\right\} \rho_{air,2} = 0.07117 \text{lbm/ft}^3$$

Analysis The error involved as a result of assuming constant air density is then determined to be

Air
80°F
14.7 psia
RH_1=30%
RH_2=90%

$$\%\,\text{Error} = \frac{\Delta\rho_{air}}{\rho_{air,1}} \times 100 = \frac{0.0727 - 0.0712 \text{ lbm/ft}^3}{0.0727 \text{ lbm/ft}^3} \times 100 = \mathbf{2.1\%}$$

which is acceptable for most engineering purposes.

14-23 The diffusion coefficient of hydrogen in steel is given as a function of temperature. The diffusion coefficients from 200 K to 1200 K in 200 K increments are to be determined and plotted.

Properties The diffusion coefficient of hydrogen in steel between 200 K and 1200 K is given as

$$D_{AB} = 1.65 \times 10^{-6} \exp(-4630/T) \qquad \text{m}^2/\text{s}$$

Analysis Using the relation above, the diffusion coefficients are calculated, and the results are tabulated and plotted below:

T (K)	D_{AB}, m^2/s
200	1.457×10^{-16}
400	1.550×10^{-11}
600	7.348×10^{-10}
800	5.058×10^{-9}
1000	1.609×10^{-8}
1200	3.482×10^{-8}

Boundary Conditions

14-25C Three boundary conditions for mass transfer (on mass basis) that correspond to specified temperature, specified heat flux, and convection boundary conditions in heat transfer are expressed as follows:

1) $w(0) = w_0$ (specified concentration - corresponds to specified temperature)

2) $-\rho D_{\text{AB}} \left.\dfrac{dw_A}{dx}\right|_{x=0} = J_{A,0}$ (specified mass flux - corresponds to specified heat flux)

3) $j_{\text{A,s}} = -D_{\text{AB}} \left.\dfrac{\partial w_{\text{A}}}{\partial y}\right|_{x=0} = h_{\text{mass}}(w_{A,s} - w_{A,\infty})$ (mass convection - corresponds to heat convection)

14-26C An impermeable surface is a surface that does not allow any mass to pass through. Mathematically it is expressed (at $x = 0$) as

$$\left.\frac{dw_A}{dx}\right|_{x=0} = 0$$

An impermeable surface in mass transfer corresponds to an insulated surface in heat transfer.

14-27C Temperature is necessarily a *continuous* function, but concentration, in general, is not. Therefore, the mole fraction of water vapor in air will, in general, be different from the mole fraction of water in the lake (which is nearly 1).

14-28C When prescribing a boundary condition for mass transfer at a solid-gas interface, we need to specify the side of the surface (whether the solid or the gas side). This is because concentration, in general, is not a continuous function, and there may be large differences in concentrations on the gas and solid sides of the boundary. We did not do this in heat transfer because temperature is a continuous function.

14-29C The mole fraction of the water vapor at the surface of a lake when the temperature of the lake surface and the atmospheric pressure are specified can be determined from

$$y_{\text{vapor}} = \frac{P_{\text{vapor}}}{P} = \frac{P_{\text{sat@T}}}{P_{\text{atm}}}$$

where P_{vapor} is equal to the saturation pressure of water at the lake surface temperature.

14-30C Using solubility data of a solid in a specified liquid, the mass fraction w of the solid A in the liquid at the interface at a specified temperature can be determined from

$$w_A = \frac{m_{\text{solid}}}{m_{\text{solid}} + m_{\text{liquid}}}$$

where m_{solid} is the maximum amount of solid dissolved in the liquid of mass m_{liquid} at the specified temperature.

14-31C The molar concentration C_{i} of the gas species i in the solid at the interface $C_{\text{i, solid side}}(0)$ is proportional to the *partial pressure* of the species i in the gas $P_{\text{i, gas side}}(0)$ on the gas side of the interface, and is determined from

$$C_{\text{i, solid side}}(0) = \mathcal{S} \times P_{\text{i, gas side}}(0) \qquad (\text{kmol/m}^3)$$

where $\mathcal{S}$ is the *solubility* of the gas in that solid at the specified temperature.

14-32C Using Henry's constant data for a gas dissolved in a liquid, the mole fraction of the gas dissolved in the liquid at the interface at a specified temperature can be determined from Henry's law expressed as

$$y_{\text{i, liquid side}}(0) = \frac{P_{\text{i, gas side}}(0)}{H}$$

where H is *Henry's constant* and $P_{\text{i, gas side}}(0)$ is the partial pressure of the gas i at the gas side of the interface. This relation is applicable for dilute solutions (gases that are weakly soluble in liquids).

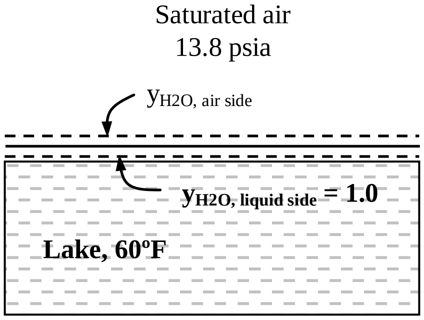
14-33C The permeability is a measure of the ability of a gas to penetrate a solid. The permeability of a gas in a solid, P**,** is related to the solubility of the gas by $\text{P} = \text{S}D_{\text{AB}}$ where D_{AB} is the diffusivity of the gas in the solid.

14-34E The mole fraction of the water vapor at the surface of a lake and the mole fraction of water in the lake are to be determined and compared.

Assumptions **1** Both the air and water vapor are ideal gases. **2** Air is weakly soluble in water and thus Henry's law is applicable.

Properties The saturation pressure of water at 60°F is 0.2563 psia (Table A-9E). Henry's constant for air dissolved in water at 60ºF (289 K) is given in Table 14-6 to be H = 62,000 bar.

Analysis The air at the water surface will be saturated. Therefore, the partial pressure of water vapor in the air at the lake surface will simply be the saturation pressure of water at 15°C,



$$P_{vapor} = P_{sat@60°F} = 0.2563 \text{ psia}$$

Assuming both the air and vapor to be ideal gases, the mole fraction of water vapor in the air at the surface of the lake is determined from Eq. 14-11 to be

$$y_{vapor} = \frac{P_{vapor}}{P} = \frac{0.2563 \text{ psia}}{13.8 \text{ psia}} = \mathbf{0.0186 \text{ (or 1.86 percent)}}$$

The partial pressure of dry air just above the lake surface is

$$P_{dry\ air} = P - P_{vapor} = 13.8 - 0.2563 = 13.54 \text{ psia}$$

Then the mole fraction of air in the water becomes

$$y_{dry\ air, liquid\ side} = \frac{P_{dry\ air, gas side}}{H} = \frac{13.54 \text{ psia}(1 \text{ atm}/14.696 \text{ psia})}{62{,}000 \text{ bar}(1 \text{ atm}/1.01325 \text{ bar})} = 1.51\times10^{-5}$$

which is very small, as expected. Therefore, the mole fraction of water in the lake near the surface is

$$y_{water, liquid\ side} = 1 - y_{dry\ air,\ liquid\ side} = 1 - 1.51\times10^{-5} = \mathbf{0.9999}$$

Discussion The concentration of air in water just below the air-water interface is 1.51 moles per 100,000 moles. The amount of air dissolved in water will decrease with increasing depth.

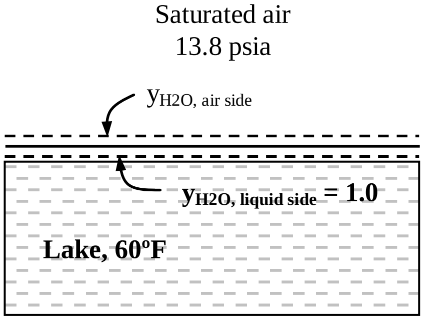
14-35 The mole fraction of the water vapor at the surface of a lake at a specified temperature is to be determined.

Assumptions **1** Both the air and water vapor are ideal gases. **2** Air at the lake surface is saturated.

Properties The saturation pressure of water at 15°C is 1.705 kPa (Table A-9).

Analysis The air at the water surface will be saturated. Therefore, the partial pressure of water vapor in the air at the lake surface will simply be the saturation pressure of water at 15°C,

$$P_{\text{vapor}} = P_{\text{sat@15°C}} = 1.705 \text{ kPa}$$



Saturated air
13.8 psia
$y_{\text{H2O, air side}}$
$y_{\text{H2O, liquid side}} = 1.0$
Lake, 60ºF

Assuming both the air and vapor to be ideal gases, the partial pressure and mole fraction of dry air in the air at the surface of the lake are determined to be

$$P_{\text{dry air}} = P - P_{\text{vapor}} = 100 - 1.705 = 98.295 \text{ kPa}$$

$$y_{\text{dry air}} = \frac{P_{\text{dry air}}}{P} = \frac{98.295 \text{ kPa}}{100 \text{ kPa}} = \mathbf{0.983} \quad \text{(or 98.3\%)}$$

Therefore, the mole fraction of dry air is 98.3 percent just above the air-water interface.

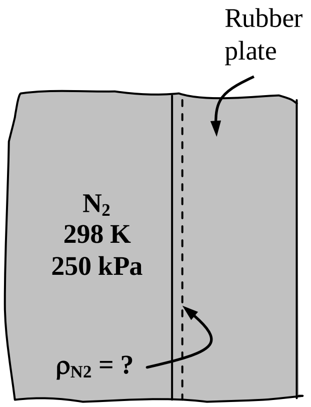
14-37 A rubber plate is exposed to nitrogen. The molar and mass density of nitrogen in the rubber at the interface is to be determined.

Assumptions Rubber and nitrogen are in thermodynamic equilibrium at the interface.

Properties The molar mass of nitrogen is M = 28.0 kg/kmol (Table A-1). The solubility of nitrogen in rubber at 298 K is 0.00156 kmol/m^3·bar (Table 14-7).



Analysis Noting that 250 kPa = 2.5 bar, the molar density of nitrogen in the rubber at the interface is determined from Eq. 14-20 to be

$$\begin{aligned} C_{\mathrm{N_2,\,solid\ side}}(0) &= \mathcal{S}\times P_{\mathrm{N_2,\,gas\ side}} \\ &= (0.00156\ \mathrm{kmol/m^3.bar})(2.5\ \mathrm{bar}) \\ &= \mathbf{0.0039\ kmol/m^3} \end{aligned}$$

It corresponds to a mass density of

$$\begin{aligned} \rho_{\mathrm{N_2,\,solid\ side}}(0) &= C_{\mathrm{N_2,\,solid\ side}}(0)\,M_{\mathrm{N_2}} \\ &= (0.0039\ \mathrm{kmol/m^3})(28\ \mathrm{kmol/kg}) \\ &= \mathbf{0.1092\ kg/m^3} \end{aligned}$$

That is, there will be 0.0039 kmol (or 0.1092 kg) of N$_2$ gas in each m^3 volume of rubber adjacent to the interface.

14-38 A rubber wall separates O_2 and N_2 gases. The molar concentrations of O_2 and N_2 in the wall are to be determined.

Assumptions The O_2 and N_2 gases are in phase equilibrium with the rubber wall.

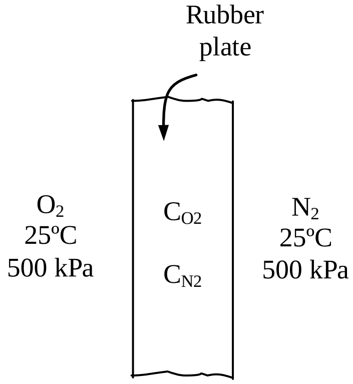
Properties The molar mass of oxygen and nitrogen are 32.0 and 28.0 kg/kmol, respectively (Table A-1). The solubility of oxygen and nitrogen in rubber at 298 K are 0.00312 and 0.00156kmol/m^3·bar, respectively (Table 14-7).

Analysis Noting that 500 kPa = 5 bar, the molar densities of oxygen and nitrogen in the rubber wall are determined from Eq. 14-20 to be

$$\begin{aligned} C_{O_2,\text{solid side}}(0) &= \mathsf{S}\times P_{O_2,\text{gas side}} \\ &= (0.00312\ \text{kmol/m}^3\text{.bar})(5\ \text{bar}) \\ &= \mathbf{0.0156\ kmol/m^3} \end{aligned}$$

$$\begin{aligned} C_{N_2,\text{solid side}}(0) &= \mathsf{S}\times P_{N_2,\text{gas side}} \\ &= (0.00156\ \text{kmol/m}^3\text{.bar})(5\ \text{bar}) \\ &= \mathbf{0.0078\ kmol/m^3} \end{aligned}$$

That is, there will be 0.0156 kmol of 039 kmol of O_2 and 0.0078 kmol of N_2 gas in each m^3 volume of the rubber wall.



14-39 A glass of water is left in a room. The mole fraction of the water vapor in the air and the mole fraction of air in the water are to be determined when the water and the air are in thermal and phase equilibrium.

Assumptions **1** Both the air and water vapor are ideal gases. **2** Air is saturated since the humidity is 100 percent. **3** Air is weakly soluble in water and thus Henry's law is applicable.

Properties The saturation pressure of water at 20°C is 2.339 kPa (Table A-9). Henry's constant for air dissolved in water at 20ºC (293 K) is given in Table 14-6 to be H = 65,600 bar. Molar masses of dry air and water are 29 and 18 kg/kmol, respectively (Table A-1).

Analysis (*a*) Noting that air is saturated, the partial pressure of water vapor in the air will simply be the saturation pressure of water at 20°C,

$$P_{\text{vapor}} = P_{sat@20°C} = 2.339\ \text{kPa}$$

Assuming both the air and vapor to be ideal gases, the mole fraction of water vapor in the air is determined to be

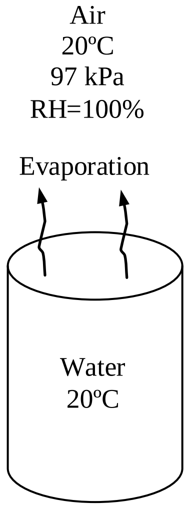
$$y_{\text{vapor}} = \frac{P_{\text{vapor}}}{P} = \frac{2.339\ \text{kPa}}{97\ \text{kPa}} = \mathbf{0.0241}$$

(*b*) Noting that the total pressure is 97 kPa, the partial pressure of dry air is

$$P_{dry\ air} = P - P_{vapor} = 97 - 2.339 = 94.7\,\text{kPa} = 0.94\ \text{bar}$$

From Henry's law, the mole fraction of air in the water is determined to be

$$y_{\text{dry air,liquid side}} = \frac{P_{\text{dry air,gas side}}}{H} = \frac{0.947\ \text{bar}}{65{,}600\,\text{bar}} = \mathbf{1.44\times 10^{-5}}$$

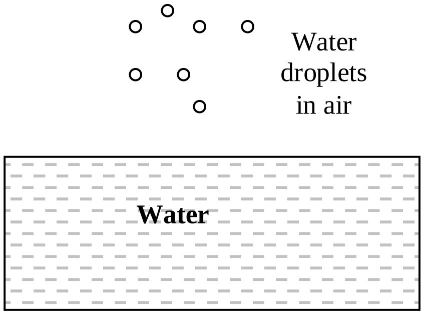


Discussion The amount of air dissolved in water is very small, as expected.

14-40E Water is sprayed into air, and the falling water droplets are collected in a container. The mass and mole fractions of air dissolved in the water are to be determined.

Assumptions **1** Both the air and water vapor are ideal gases. **2** Air is saturated since water is constantly sprayed into it. **3** Air is weakly soluble in water and thus Henry's law is applicable.

Properties The saturation pressure of water at 80°F is 0.5073 psia (Table A-9E). Henry's constant for air dissolved in water at 80ºF (300 K) is given in Table 14-6 to be H = 74,000 bar. Molar masses of dry air and water are 29 and 18 lbm / lbmol, respectively (Table A-1).



Analysis Noting that air is saturated, the partial pressure of water vapor in the air will simply be the saturation pressure of water at 80°F,

$$P_{\text{vapor}} = P_{\text{sat@80°F}} = 0.5073 \text{ psia}$$

Then the partial pressure of dry air becomes

$$P_{\text{dry air}} = P - P_{\text{vapor}} = 14.3 - 0.5073 = 13.79 \text{ psia}$$

From Henry's law, the mole fraction of air in the water is determined to be

$$y_{\text{dry air,liquid side}} = \frac{P_{\text{dry air,gasside}}}{H} = \frac{13.79 \text{ psia}(1 \text{ atm}/14.696 \text{ psia})}{74{,}000 \text{ bar}\,(1 \text{ atm}/1.01325 \text{ bar})} = \mathbf{1.29 \times 10^{-5}}$$

which is very small, as expected. The mass and mole fractions of a mixture are related to each other by

$$w_i = \frac{m_i}{m_m} = \frac{N_i M_i}{N_m M_m} = y_i \frac{M_i}{M_m}$$

where the apparent molar mass of the liquid water - air mixture is

$$M_m = \sum y_i M_i = y_{\text{liquid water}} M_{\text{water}} + y_{\text{dry air}} M_{\text{dry air}}$$
$$\cong 1 \times 29.0 + 0 \times 18.0 \cong 29.0 \text{ kg/kmol}$$

Then the mass fraction of dissolved air in liquid water becomes

$$w_{\text{dryair, liquidside}} = y_{\text{dryair, liquidside}}(0)\frac{M_{\text{dryair}}}{M_m} = 1.29 \times 10^{-5}\,\frac{29}{29} = \mathbf{1.29 \times 10^{-5}}$$

Discussion The mass and mole fractions of dissolved air in this case are identical because of the very small amount of air in water.

14-41 A carbonated drink in a bottle is considered. Assuming the gas space above the liquid consists of a saturated mixture of CO_2 and water vapor and treating the drink as a water, determine the mole fraction of the water vapor in the CO_2 gas and the mass of dissolved CO_2 in a 200 ml drink are to be determined when the water and the CO_2 gas are in thermal and phase equilibrium.

Assumptions **1** The liquid drink can be treated as water. **2** Both the CO_2 and the water vapor are ideal gases. **3** The CO_2 gas and water vapor in the bottle from a saturated mixture. **4** The CO_2 is weakly soluble in water and thus Henry's law is applicable.

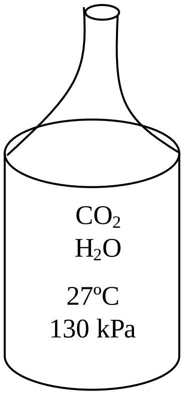
Properties The saturation pressure of water at 27°C is 3.60 kPa (Table A-9). Henry's constant for CO_2 dissolved in water at 27ºC (300 K) is given in Table 14-6 to be H = 1710 bar. Molar masses of CO_2 and water are 44 and 18 kg/kmol, respectively (Table A-1).

Analysis (*a*) Noting that the CO_2 gas in the bottle is saturated, the partial pressure of water vapor in the air will simply be the saturation pressure of water at 27°C,

$$P_{\text{vapor}} = P_{sat@27°C} = 3.60 \text{ kPa}$$

Assuming both CO_2 and vapor to be ideal gases, the mole fraction of water vapor in the CO_2 gas becomes

$$y_{\text{vapor}} = \frac{P_{\text{vapor}}}{P} = \frac{3.60 \text{ kPa}}{130 \text{ kPa}} = \mathbf{0.0277}$$



(*b*) Noting that the total pressure is 130 kPa, the partial pressure of CO_2 is

$$P_{CO_2\text{ gas}} = P - P_{vapor} = 130 - 3.60 = 126.4 \text{ kPa} = 1.264 \text{ bar}$$

From Henry's law, the mole fraction of CO_2 in the drink is determined to be

$$y_{CO_2,\text{liquid side}} = \frac{P_{CO_2,\text{gas side}}}{H} = \frac{1.264 \text{ bar}}{1710 \text{ bar}} = \mathbf{7.39 \times 10^{-4}}$$

Then the mole fraction of water in the drink becomes

$$y_{\text{water, liquid side}} = 1 - y_{CO_2,\text{ liquid side}} = 1 - 7.39 \times 10^{-4} = 0.9993$$

The mass and mole fractions of a mixture are related to each other by

$$w_i = \frac{m_i}{m_m} = \frac{N_i M_i}{N_m M_m} = y_i \frac{M_i}{M_m}$$

where the apparent molar mass of the drink (liquid water - CO_2 mixture) is

$$M_m = \sum y_i M_i = y_{\text{liquid water}} M_{\text{water}} + y_{CO_2} M_{CO_2} = 0.9993 \times 18.0 + (7.39 \times 10^{-4}) \times 18.0 = 18.02 \text{ kg/kmol}$$

Then the mass fraction of dissolved CO_2 gas in liquid water becomes

$$w_{CO_2,\text{ liquid side}} = y_{CO_2,\text{ liquid side}}(0)\frac{M_{CO_2}}{M_m} = 7.39 \times 10^{-4} \frac{44}{18.02} = 0.00180$$

Therefore, the mass of dissolved CO_2 in a 200 ml ≈ 200 g drink is

$$m_{CO_2} = w_{CO_2} m_m = 0.00180(200 \text{ g}) = \mathbf{0.360 \text{ g}}$$

Steady Mass Diffusion Through a Wall

14-42C The relations for steady one-dimensional heat conduction and mass diffusion through a plane wall are expressed as follows:

Heat conduction: $$\dot{Q}_{cond} = -k\,A\frac{T_1 - T_2}{L}$$

Mass diffusion: $$\dot{m}_{\text{diff,A,wall}} = \rho D_{\text{AB}} A\frac{w_{\text{A},1} - w_{\text{A},2}}{L} = D_{\text{AB}} A\frac{\rho_{\text{A},1} - \rho_{\text{A},2}}{L}$$

where *A* is the normal area and *L* is the thickness of the wall, and the other variables correspond to each other as follows:

rate of heat conduction	$\dot{Q}_{\text{cond}} \longleftrightarrow \dot{m}_{\text{diff,A,wall}}$	rate of mass diffusion
thermal conductivity	$k \longleftrightarrow D_{\text{AB}}$	mass diffusivity
temperature	$T \longleftrightarrow \rho_{\text{A}}$	density of *A*

14-43C (*a*) T, (*b*) F, (*c*) T, (*d*) F

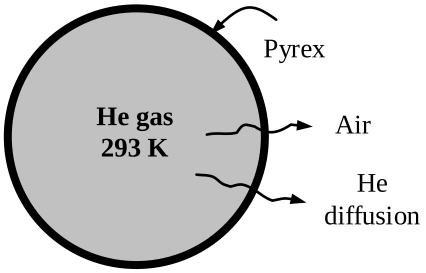
14-44C During one-dimensional mass diffusion of species *A* through a plane wall of thickness *L*, the concentration profile of species *A* in the wall will be a straight line when (1) steady operating conditions are established, (2) the concentrations of the species *A* at both sides are maintained constant, and (3) the diffusion coefficient is constant.

14-45C During one-dimensional mass diffusion of species *A* through a plane wall, the species *A* content of the wall will remain constant during steady mass diffusion, but will change during transient mass diffusion.

14-46 Pressurized helium gas is stored in a spherical container. The diffusion rate of helium through the container is to be determined.

Assumptions **1** Mass diffusion is *steady* and *one-dimensional* since the helium concentration in the tank and thus at the inner surface of the container is practically constant, and the helium concentration in the atmosphere and thus at the outer surface is practically zero. Also, there is symmetry about the center of the container. **2** There are no chemical reactions in the pyrex shell that results in the generation or depletion of helium.

Properties The binary diffusion coefficient of helium in the pyrex at the specified temperature is 4.5×10^{-15} m^2/s (Table 14-3b). The molar mass of helium is $M = 4$ kg/kmol (Table A-1).



Analysis We can consider the total molar concentration to be constant ($C = C_A + C_B \cong C_B$ = constant), and the container to be a *stationary* medium since there is no diffusion of pyrex molecules ($\dot{N}_B = 0$) and the concentration of the helium in the container is extremely low ($C_A << 1$). Then the molar flow rate of helium through the shell by diffusion can readily be determined from Eq. 14-28 to be

$$\begin{aligned}\dot{N}_{\text{diff}} &= 4\pi r_1 r_2 D_{AB}\frac{C_{A,1}-C_{A,2}}{r_2-r_1}\\ &= 4\pi(1.45\text{ m})(1.50\text{ m})(4.5\times10^{-15}\text{ m}^2/\text{s})\frac{(0.00073-0)\text{ kmol/m}^3}{1.50-1.45}\\ &= 1.80\times10^{-15}\text{ kmol/s}\end{aligned}$$

The mass flow rate is determined by multiplying the molar flow rate by the molar mass of helium,

$$\dot{m}_{\text{diff}} = M\dot{N}_{\text{diff}} = (4\text{ kg/kmol})(1.80\times10^{-15}\text{ kmol/s}) = \mathbf{7.2\times10^{-15}\ kg/s}$$

Therefore, helium will leak out of the container through the shell by diffusion at a rate of 7.2×10^{-15} kg/s or 0.00023 g/year.

Discussion Note that the concentration of helium in the pyrex at the inner surface depends on the temperature and pressure of the helium in the tank, and can be determined as explained in the previous example. Also, the assumption of zero helium concentration in pyrex at the outer surface is reasonable since there is only a trace amount of helium in the atmosphere (0.5 parts per million by mole numbers).

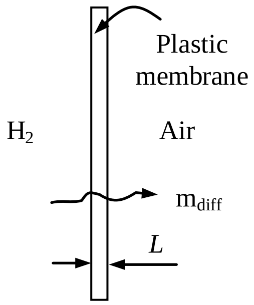
14-47 A thin plastic membrane separates hydrogen from air. The diffusion rate of hydrogen by diffusion through the membrane under steady conditions is to be determined.

Assumptions **1** Mass diffusion is *steady* and *one-dimensional* since the hydrogen concentrations on both sides of the membrane are maintained constant. Also, there is symmetry about the center plane of the membrane. **2** There are no chemical reactions in the membrane that results in the generation or depletion of hydrogen.

Properties The binary diffusion coefficient of hydrogen in the plastic membrane at the operation temperature is given to be 5.3×10^{-10} m^2/s. The molar mass of hydrogen is $M = 2$ kg/kmol (Table A-1).

Analysis (*a*) We can consider the total molar concentration to be constant ($C = C_A + C_B \cong C_B =$ constant), and the plastic membrane to be a *stationary* medium since there is no diffusion of plastic molecules ($\dot{N}_B = 0$) and the concentration of the hydrogen in the membrane is extremely low ($C_A << 1$). Then the molar flow rate of hydrogen through the membrane by diffusion per unit area is determined from

$$\bar{j}_{\text{diff}} = \frac{\dot{N}_{\text{diff}}}{A} = D_{AB}\frac{C_{A,1} - C_{A,2}}{L}$$
$$= (5.3\times10^{-10}\ \text{m}^2/\text{s})\frac{(0.065 - 0.003)\ \text{kmol/m}^3}{2\times10^{-3}\ \text{m}}$$
$$= 1.64\times10^{-8}\ \text{kmol/m}^2.\text{s}$$



The mass flow rate is determined by multiplying the molar flow rate by the molar mass of hydrogen,

$$\dot{m}_{\text{diff}} = M\,\bar{j}_{\text{diff}} = (2\ \text{kg/kmol})(1.64\times10^{-8}\ \text{kmol/m}^2.\text{s})$$
$$= \mathbf{3.29\times10^{-8}\ kg/m^2.s}$$

(*b*) Repeating the calculations for a 0.5-mm thick membrane gives

$$\bar{j}_{\text{diff}} = \frac{\dot{N}_{\text{diff}}}{A} = D_{AB}\frac{C_{A,1} - C_{A,2}}{L}$$
$$= (5.3\times10^{-10}\ \text{m}^2/\text{s})\frac{(0.065 - 0.003)\ \text{kmol/m}^3}{0.5\times10^{-3}\ \text{m}}$$
$$= 6.57\times10^{-8}\ \text{kmol/m}^2.\text{s}$$

and

$$\dot{m}_{\text{diff}} = M\,\bar{j}_{\text{diff}} = (2\ \text{kg/kmol})(6.57\times10^{-8}\ \text{kmol/m}^2.\text{s}) = \mathbf{1.31\times10^{-7}\ kg/m^2.s}$$

The mass flow rate through the entire membrane can be determined by multiplying the mass flux value above by the membrane area.

14-48 Natural gas with 8% hydrogen content is transported in an above ground pipeline. The highest rate of hydrogen loss through the pipe at steady conditions is to be determined.

Assumptions **1** Mass diffusion is *steady* and *one-dimensional* since the hydrogen concentrations inside the pipe is constant, and in the atmosphere it is negligible. Also, there is symmetry about the centerline of the pipe. **2** There are no chemical reactions in the pipe that results in the generation or depletion of hydrogen. **3** Both H_2 and CH_4 are ideal gases.

Properties The binary diffusion coefficient of hydrogen in the steel pipe at the operation temperature is given to be 2.9×10^{-13} m^2/s. The molar masses of H_2 and CH_4 are 2 and 16 kg/kmol, respectively (Table A-1). The solubility of hydrogen gas in steel is given as $w_{H_2} = 2.09\times10^{-4}\exp(-3950/T)P_{H_2}^{0.5}$. The density of steel pipe is 7854 kg/m^3.

Analysis We can consider the total molar concentration to be constant ($C = C_A + C_B \cong C_B$ = constant), and the steel pipe to be a *stationary* medium since there is no diffusion of steel molecules ($\dot{N}_B = 0$) and the concentration of the hydrogen in the steel pipe is extremely low ($C_A << 1$). The molar mass of the H_2 and CH_4 mixture in the pipe is

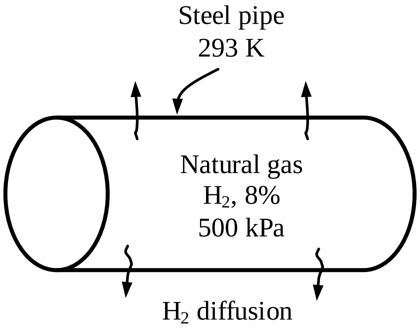
$$M = \sum y_i M_i = (0.08)(2) + (0.92)(16) = 14.88 \text{ kg/kmol}$$

Noting that the mole fraction of hydrogen is 0.08, the partial pressure of hydrogen is

$$y_{H_2} = \frac{P_{H_2}}{P} \rightarrow P_{H_2} = (0.08)(500 \text{ kPa}) = 40 \text{ kPa} = 0.4 \text{ bar}$$

Then the mass fraction of hydrogen becomes

$$\begin{aligned} w_{H_2} &= 2.09\times10^{-4}\exp(-3950/T)P_{H_2}{}^{0.5} \\ &= 2.09\times10^{-4}\exp(-3950/293)(0.4)^{0.5} \\ &= 1.85\times10^{-10} \end{aligned}$$



The hydrogen concentration in the atmosphere is practically zero, and thus in the limiting case the hydrogen concentration at the outer surface of pipe can be taken to be zero. Then the highest rate of hydrogen loss through a 100 m long section of the pipe at steady conditions is determined to be

$$\begin{aligned} \dot{m}_{\text{diff,A,cyl}} &= 2\pi L\rho D_{AB}\frac{w_{A,1} - w_{A,2}}{\ln(r_2/r_1)} \\ &= 2\pi(100\text{m})(7854\text{kg/m}^3)(2.9\times10^{-13})\frac{1.85\times10^{-10} - 0}{\ln(1.51/1.50)} \\ &= \mathbf{3.98\times10^{-14}\ kg/s} \end{aligned}$$

14-50 Helium gas is stored in a spherical fused silica container. The diffusion rate of helium through the container and the pressure drop in the tank in one week as a result of helium loss are to be determined.

Assumptions **1** Mass diffusion is *steady* and *one-dimensional* since the helium concentration in the tank and thus at the inner surface of the container is practically constant, and the helium concentration in the atmosphere and thus at the outer surface is practically zero. Also, there is symmetry about the midpoint of the container. **2** There are no chemical reactions in the fused silica that results in the generation or depletion of helium. **3** Helium is an ideal gas. **4** The helium concentration at the inner surface of the container is at the highest possible level (the solubility).

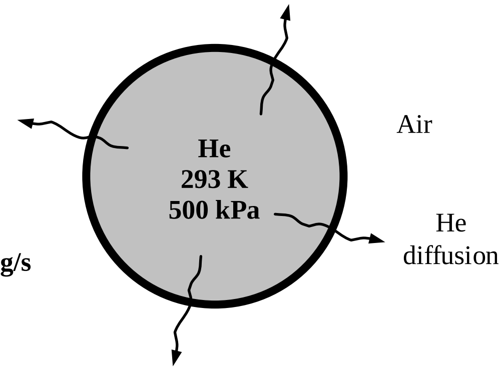
Properties The solubility of helium in fused silica (SiO_2) at 293 K and 500 kPa is 0.00045 kmol /m^3.bar (Table 14-7). The diffusivity of hydrogen in fused silica at 293 K (actually, at 298 K) is 4×10^{-14} m^2/s (Table 14-3b). The molar mass of helium is M = 4 kg/kmol (Table A-1).

Analysis (*a*) We can consider the total molar concentration to be constant ($C = C_A + C_B \cong C_B$ = constant), and the container to be a *stationary* medium since there is no diffusion of silica molecules ($\dot{N}_B = 0$) and the concentration of the helium in the container is extremely low ($C_A << 1$). The molar concentration of helium at the inner surface of the container is determined from the solubility data to be

$$C_{A,1} = S \times P_{\text{He}} = (0.00045\,\text{kmol/m}^3.\text{bar})(5\text{bar}) = 2.25\times10^{-3}\,\text{kmol/m}^3 = 0.00225\,\text{kmol/m}^3$$

The hydrogen concentration in the atmosphere and thus at the outer surface is taken to be zero since the tank is well ventilated. Then the molar flow rate of helium through the tank by diffusion becomes

$$\begin{aligned}\dot{N}_{\text{diff}} &= 4\pi r_1 r_2 D_{AB}\frac{C_{A,1}-C_{A,2}}{r_2-r_1}\\ &= 4\pi(1\text{m})(1.01\text{m})(4\times10^{-14}\,\text{m}^2/\text{s})\frac{(0.00225\text{ - }0)\text{kmol/m}^3}{(1.01\text{ - }1)\text{m}}\\ &= 1.14\times10^{-13}\,\text{kmol/s}\end{aligned}$$



The mass flow rate is determined by multiplying the molar flow rate by the molar mass of helium,

$$\dot{m}_{\text{diff}} = M\dot{N}_{\text{diff}} = (4\,\text{kg/kmol})(1.14\times10^{-13}\,\text{kmol/s}) = \mathbf{4.57\times10^{-13}\ kg/s}$$

(*b*) Noting that the molar flow rate of helium is 1.14 $\times10^{-13}$ kmol / s, the amount of helium diffused through the shell in 1 week becomes

$$\begin{aligned}N_{\text{diff}} &= N_{\text{diff}}\Delta t = (1.14\times10^{-13}\ \text{kmol/s})(7\times24\times3600\ \text{s/week})\\ &= 6.908\times10^{-8}\ \text{kmol/week}\end{aligned}$$

The volume of the spherical tank and the initial amount of helium gas in the tank are

$$V = \frac{4}{3}\pi r^3 = \frac{4}{3}\pi(1\text{m})^3 = 4.18\,\text{m}^3$$

$$N_{\text{initial}} = \frac{PV}{R_u T} = \frac{(500\,\text{kPa})(4.18\,\text{m}^3)}{(8.314\,\text{kPam}^3/\text{kmolK})(293\text{K})} = 0.85796\,\text{kmol}$$

Then the number of moles of helium remaining in the tank after one week becomes

$$N_{\text{final}} = N_{\text{initial}} - N_{\text{diff}} = 0.85796 - 6.908\times10^{-8} \cong 0.85796\ \text{kPa}$$

which is the practically the same as the initial value (in 6 significant digits). Therefore, the amount of helium that leaves the tank by diffusion is negligible, and the final pressure in the tank is the same as the initial pressure of $P_2 = P_1 =$ **500 kPa.**

14-51 A balloon is filled with helium gas. The initial rates of diffusion of helium, oxygen, and nitrogen through the balloon and the mass fraction of helium that escapes during the first 5 h are to be determined.

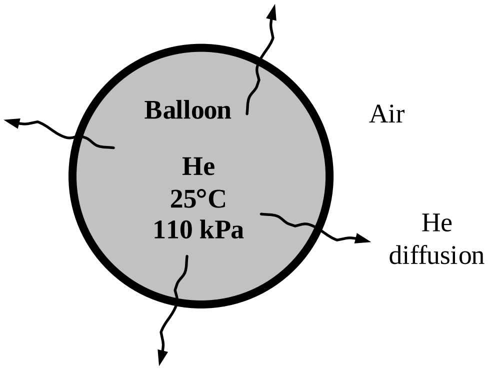
Assumptions **1** The pressure of helium inside the balloon remains nearly constant. **2** Mass diffusion is *steady* for the time period considered. **3** Mass diffusion is *one-dimensional* since the helium concentration in the balloon and thus at the inner surface is practically constant, and the helium concentration in the atmosphere and thus at the outer surface is practically zero. Also, there is symmetry about the midpoint of the balloon. **4** There are no chemical reactions in the balloon that results in the generation or depletion of helium. **5** Both the helium and the air are ideal gases. **7** The curvature effects of the balloon are negligible so that the balloon can be treated as a plane layer.

Properties The permeability of rubber to helium, oxygen, and nitrogen at 25°C are given to be 9.4×10^{-13}, 7.05×10^{-13}, and 2.6×10^{-13} kmol/m.s.bars, respectively. The molar mass of helium is M = 4 kg/kmol and its gas constant is R = 2.0709 kPa.m^3/kg.K (Table A-1).

Analysis We can consider the total molar concentration to be constant ($C = C_A + C_B \cong C_B$ = constant), and the balloon to be a *stationary* medium since there is no diffusion of rubber molecules ($\dot{N}_B = 0$) and the concentration of the helium in the balloon is extremely low (C_A << 1). The partial pressures of oxygen and nitrogen in the air are

$$P_{N_2} = y_{N_2}P = (0.79)(100\text{ kPa}) = 79\text{ kPa} = 0.79\text{ bar}$$

$$P_{O_2} = y_{O_2}P = (0.21)(100\text{ kPa}) = 21\text{ kPa} = 0.21\text{ bar}$$



The partial pressure of helium in the air is negligible. Since the balloon is filled with pure helium gas at 110 kPa, the initial partial pressure of helium in the balloon is 110 kPa, and the initial partial pressures of oxygen and nitrogen are zero.

When permeability data is available, the molar flow rate of a gas through a solid wall of thickness L under steady one-dimensional conditions can be determined from Eq. 14-29,

$$\dot{N}_{\text{diff,A,wall}} = \mathsf{P}_{AB}A\frac{P_{A,1}-P_{A,2}}{L} \qquad \text{(kmol/s)}$$

where P_{AB} is the permeability and $P_{A,1}$ and $P_{A,2}$ are the partial pressures of gas A on the two sides of the wall (Note that the balloon can be treated as a plain layer since its thickness is very small compared to its diameter). Noting that the surface area of the balloon is $A = \pi D^2 = \pi(0.15\text{ m})^2 = 0.07069\text{ m}^2$, the initial rates of diffusion of helium, oxygen, and nitrogen at 25ºC are determined to be

$$\dot{N}_{\text{diff,He}} = \mathsf{P}_{AB}A\frac{P_{\text{He},1}-P_{\text{He},2}}{L}$$
$$= (9.4\times10^{-13}\text{ kmol/m.s.bar})(0.07069\text{ m}^2)\frac{(1.1-0)\text{bar}}{0.1\times10^{-3}\text{ m}} = \mathbf{0.731\times10^{-9}\ kmol/s}$$

$$\dot{N}_{\text{diff,O}_2} = \mathsf{P}_{AB}A\frac{P_{O_2,1}-P_{O_2,2}}{L}$$
$$= (7.05\times10^{-13}\text{ kmol/m.s.bar})(0.07069\text{ m}^2)\frac{(0-0.21)\text{bar}}{0.1\times10^{-3}\text{ m}} = \mathbf{-0.105\times10^{-9}\ kmol/s}$$

$$\dot{N}_{\text{diff,N}_2} = \mathsf{P}_{AB}A\frac{P_{N_2,1}-P_{N_2,2}}{r_2-r_1}$$
$$= (2.06\times10^{-13}\text{ kmol/m.s.bar})(0.07069\text{ m}^2)\frac{(0-0.79)\text{bar}}{0.1\times10^{-3}\text{ m}} = \mathbf{-0.115\times10^{-9}\ kmol/s}$$

The initial mass flow rate of helium and the amount of helium that escapes during the first 5 hours are

$$\dot{m}_{diff,\text{He}} = M\,\dot{N}_{diff,\text{He}} = (4\text{ kg/kmol})(0.731\times10^{-9}\text{ kmol/s}) = 2.92\times10^{-9}\text{ kg/s}$$

$$m_{\text{diff,He}} = \dot{m}_{\text{diff,He}}\Delta t = (2.92\times10^{-9}\text{ kg/s})(5\times3600\text{ s}) = \mathbf{5.26\times10^{-5}\text{ kg} = 0.0526\text{ g}}$$

The initial mass of helium in the balloon is

$$m_{\text{initial}} = \frac{PV}{RT} = \frac{(110\,\text{kPa})[4\pi(0.075\,\text{m})^3/3]}{(2.0709\,\text{kPa.m}^3/\text{kg}\cdot\text{K})(298\,\text{K})} = 3.15\times10^{-4}\text{ kg} = 0.315\text{ g}$$

Therefore, the fraction of helium that escapes the balloon during the first 5 h is

$$\text{Fraction} = \frac{m_{\text{diff,He}}}{m_{\text{initial}}} = \frac{0.0526\text{ g}}{0.315\text{ g}} = \mathbf{0.167}\text{ (or }\mathbf{16.7\%)}$$

Discussion This is a significant amount of helium gas that escapes the balloon, and explains why the helium balloons do not last long. Also, our assumption of constant pressure for the helium in the balloon is obviously not very accurate since 16.7% of helium is lost during the process.

14-52 A balloon is filled with helium gas. A relation for the variation of pressure in the balloon with time as a result of mass transfer through the balloon material is to be obtained, and the time it takes for the pressure in the balloon to drop from 110 to 100 kPa is to be determined.

Assumptions **1** The pressure of helium inside the balloon remains nearly constant. **2** Mass diffusion is *transient* since the conditions inside the balloon change with time. **3** Mass diffusion is *one-dimensional* since the helium concentration in the balloon and thus at the inner surface is practically constant, and the helium concentration in the atmosphere and thus at the outer surface is practically zero. Also, there is symmetry about the midpoint of the balloon. **4** There are no chemical reactions in the balloon material that results in the generation or depletion of helium. **5** Helium is an ideal gas. **6** The diffusion of air into the balloon is negligible. **7** The volume of the balloon is constant. **8** The curvature effects of the balloon are negligible so that the balloon material can be treated as a plane layer.

Properties The permeability of rubber to helium at 25°C is given to be 9.4×10^{-13} kmol/m.s.bar. The molar mass of helium is M = 4 kg/kmol and its gas constant is R = 2.0709 kPa.m^3/kg.K (Table A-1).

Analysis We can consider the total molar concentration to be constant ($C = C_{\rm A} + C_{\rm B} \cong C_{\rm B}$ = constant), and the balloon to be a *stationary* medium since there is no diffusion of rubber molecules ($\dot{N}_B = 0$) and the concentration of the helium in the balloon is extremely low ($C_{\rm A} << 1$). The partial pressure of helium in the air is negligible. Since the balloon is filled with pure helium gas at 110 kPa, the initial partial pressure of helium in the balloon is 110 kPa.

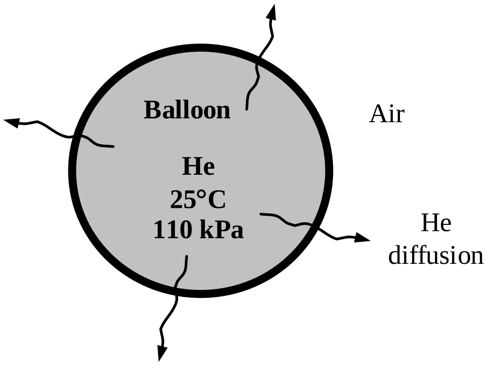
When permeability data is available, the molar flow rate of a gas through a solid wall of thickness L under steady one-dimensional conditions can be determined from Eq. 14-29,

$$\dot{N}_{\rm diff,A,wall} = \mathsf{P}_{\rm AB} A \frac{P_{\rm A,1} - P_{\rm A,2}}{L} = \mathsf{P}_{\rm AB} A \frac{P}{L} \qquad \text{(kmol/s)}$$

where $\mathsf{P}_{\rm AB}$ is the permeability and $P_{\rm A,1}$ and $P_{\rm A,2}$ are the partial pressures of helium on the two sides of the wall (note that the balloon can be treated as a plain layer since its thickness very small compared to its diameter, and $P_{\rm A,1}$ is simply the pressure P of helium inside the balloon).

Noting that the amount of helium in the balloon can be expressed as $N = PV / R_u T$ and taking the temperature and volume to be constants,

$$N = \frac{PV}{R_u T} \quad \to \quad \frac{dN}{dt} = \frac{V}{R_u T}\frac{dP}{dt} \quad \to \quad \frac{dP}{dt} = \frac{R_u T}{V}\frac{dN}{dt} \qquad (1)$$



Conservation of mass dictates that the mass flow rate of helium from the balloon be equal to the rate of change of mass inside the balloon,

$$\frac{dN}{dt} = -\dot{N}_{\rm diff,A,wall} = -\mathsf{P}_{\rm AB} A \frac{P}{L} \qquad (2)$$

Substituting (2) into (1),

$$\frac{dP}{dt} = \frac{R_u T}{V}\frac{dN}{dt} = -\frac{R_u T}{V}\mathsf{P}_{\rm AB} A \frac{P}{L} = -\frac{R_u T \mathsf{P}_{\rm AB} A}{VL} P$$

Separating the variables and integrating gives

$$\frac{dP}{P} = -\frac{R_u T \mathsf{P}_{\rm AB} A}{VL} dt \quad \to \quad \ln P\Big|_{P_0}^{P} = -\frac{R_u T \mathsf{P}_{\rm AB} A}{VL} \, t\Big|_0^t \quad \to \quad \ln\frac{P}{P_0} = -\frac{R_u T \mathsf{P}_{\rm AB} A}{VL} t$$

Rearranging, the desired relation for the variation of pressure in the balloon with time is determined to be

$$P = P_0 \exp\left(-\frac{R_u T \mathsf{P}_{\rm AB} A}{VL} t\right) = P_0 \exp\left(-\frac{3 R_u T \mathsf{P}_{\rm AB}}{rL} t\right) \qquad \text{since, for a sphere, } \frac{A}{V} = \frac{4\pi r^2}{4\pi r^3 / 3} = \frac{3}{r}$$

Then the time it takes for the pressure inside the balloon to drop from 110 kPa to 100 kPa becomes

$$\frac{100\ \text{kPa}}{110\ \text{kPa}} = \exp\left(-\frac{3(0.08314\ \text{bar}\cdot\text{m}^3/\text{kmol}\cdot\text{K})(298\ \text{K})(9.4\times10^{-13}\ \text{kmol/m}\cdot\text{s}\cdot\text{bar})}{(0.075\ \text{m})(0.1\times10^{-3}\ \text{m})} t\right) \to t = 10{,}230\ \text{s} = \mathbf{2.84\ h}$$ T

herefore, the balloon will lose 10% of its pressure in about 3 h.

14-53 Pure N_2 gas is flowing through a rubber pipe. The rate at which N_2 leaks out by diffusion is to be determined for the cases of vacuum and atmospheric air outside.

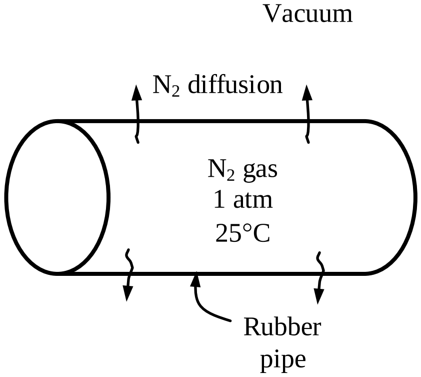
Assumptions **1** Mass diffusion is *steady* and *one-dimensional* since the nitrogen concentration in the pipe and thus at the inner surface of the pipe is practically constant, and the nitrogen concentration in the atmosphere also remains constant. Also, there is symmetry about the centerline of the pipe. **2** There are no chemical reactions in the pipe that results in the generation or depletion of nitrogen. **3** Both the nitrogen and air are ideal gases.

Properties The diffusivity and solubility of nitrogen in rubber at 25°C are 1.5×10^{-10} m^2/s and 0.00156 9 $kmol/m^3$.bar, respectively (Tables 14-3 and 14-7).

Analysis We can consider the total molar concentration to be constant ($C = C_A + C_B \cong C_B$ = constant), and the container to be a *stationary* medium since there is no diffusion of silica molecules ($\dot{N}_B = 0$) and the concentration of the helium in the container is extremely low (C_A << 1). The partial pressures of oxygen and nitrogen in the air are

$$P_{N_2} = y_{N_2} P = (0.79)(100 \text{ kPa}) = 79 \text{ kPa} = 0.79 \text{ bar}$$

$$P_{O_2} = y_{O_2} P = (0.21)(100 \text{ kPa}) = 21 \text{ kPa} = 0.21 \text{ bar}$$



The partial pressure of helium in the air is negligible. Since the balloon is filled with pure helium gas at 110 kPa, the initial partial pressure of helium in the balloon is 110 kPa, and the initial partial pressures of oxygen and nitrogen are zero.

When solubility data is available, the molar flow rate of a gas through a solid can be determined by replacing the molar concentration by $C_{A,\text{ solid side}}(0) = S_{AB} P_{A,\text{ gas side}}(0)$ where S_{AB} is the *solubility* and $P_{A,1}$ and $P_{A,2}$ are the partial pressures of gas *A* on the two sides of the wall. For a cylindrical pipe the molar rate of diffusion can be expressed in terms of solubility as

$$\dot{N}_{\text{diff,A,cyl}} = 2\pi L D_{AB} S_{AB} \frac{P_{A,1} - P_{A,2}}{\ln(r_2 / r_1)}$$

(*a*) The pipe is in vacuum and thus $P_{A,2} = 0$:

$$\dot{N}_{\text{diff,A,cyl}} = 2\pi(10 \text{ m})(1.5\times10^{-10} \text{ m}^2/\text{s})(0.00156 \text{ kmol/m}^3\cdot\text{s}\cdot\text{bar})\frac{(1\text{-}0)\text{ bar}}{\ln(0.031/0.03)}$$
$$= \mathbf{4.483\times10^{-10}\ kmol/s}$$

(*b*) The pipe is in atmospheric air and thus $P_{A,2}$ = 0.79 bar:

$$\dot{N}_{\text{diff,A,cyl}} = 2\pi(10 \text{ m})(1.5\times10^{-10} \text{ m}^2/\text{s})(0.00156 \text{ kmol/m}^3\cdot\text{s}\cdot\text{bar})\frac{(1-0.79)\text{ bar}}{\ln(0.031/0.03)}$$
$$= \mathbf{9.416\times10^{-11}\ kmol/s}$$

Discussion In the case of a vacuum environment, the diffusion rate of nitrogen from the pipe is about 5 times the rate in atmospheric air. This is expected since mass diffusion is proportional to the concentration difference.

Water Vapor Migration in Buildings

14-54C A tank that contains moist air at 3 atm is located in moist air that is at 1 atm. The driving force for moisture transfer is the vapor pressure difference, and thus it is possible for the water vapor to flow into the tank from surroundings if the vapor pressure in the surroundings is greater than the vapor pressure in the tank.

14-55C The mass flow rate of water vapor through a wall of thickness *L* in therms of the partial pressure of water vapor on both sides of the wall and the permeability of the wall to the water vapor can be expressed as

$$\dot{m}_{\text{diff,A,wall}} = \mathrm{M}\mathsf{P}_{\text{AB}} A \frac{P_{\text{A},1} - P_{\text{A},2}}{L}$$

where M is the molar mass of vapor, P_{AB} is the permeability, *A* is the normal area, and P_{A} is the partial pressure of the vapor.

14-56C The condensation or freezing of water vapor in the wall increases the thermal conductivity of the insulation material, and thus increases the rate of heat transfer through the wall. Similarly, the thermal conductivity of the soil increases with increasing amount of moisture.

14-57C Vapor barriers are materials that are impermeable to moisture such as sheet metals, heavy metal foils, and thick plastic layers, and they completely *eliminate* the vapor migration. Vapor retarders such as reinforced plastics or metals, thin foils, plastic films, treated papers and coated felts, on the other hand, *slow down* the flow of moisture through the structures. Vapor retarders are commonly used in residential buildings to control the vapor migration through the walls.

14-58C Excess moisture changes the *dimensions* of wood, and cyclic changes in dimensions weaken the joints, and can jeopardize the structural integrity of building components, causing “squeaking” at the minimum. Excess moisture can also cause *rotting* in woods, *mold* growth on wood surfaces, *corrosion* and *rusting* in metals, and *peeling of paint* on the interior and exterior wall surfaces.

14-59C Insulations on *chilled water lines* are always wrapped with *vapor barrier jackets* to eliminate the possibility of vapor entering the insulation. This is because moisture that migrates through the insulation to the cold surface will condense and remain there indefinitely with no possibility of vaporizing and moving back to the outside.

14-60C When the temperature, total pressure, and the relative humidity are given, the vapor pressure can be determined from the psychrometric chart or the relation $P_v = \phi P_{\text{sat}}$ where P_{sat} is the saturation (or boiling) pressure of water at the specified temperature and ϕ is the relative humidity.

14-61 The inside wall of a house is finished with 9.5-mm thick gypsum wallboard. The maximum amount of water vapor that will diffuse through a 3 m × 8 m section of the wall in 24-h is to be determined.

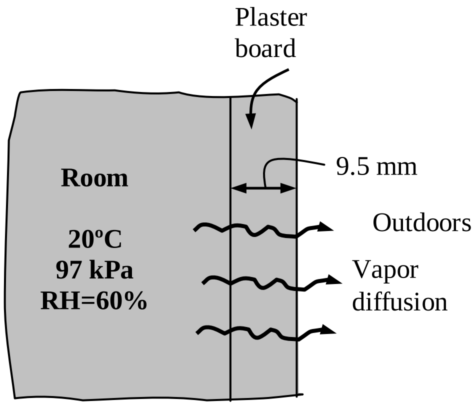
Assumptions **1** Steady operating conditions exist. **2** Mass transfer through the wall is one-dimensional. **3** The vapor permeability of the wall is constant. **4** The vapor pressure at the outer side of the wallboard is zero.

Properties The permeance of the 9.5 mm thick gypsum wall board to water vapor is given to be 2.86×10^{-9} kg/s.m^2.Pa. (Table 14-10). The saturation pressure of water at 20ºC is 2339 Pa (Table 14-9).

Analysis The mass flow rate of water vapor through a plain layer of thickness *L* and normal area *A* is given as (Eq. 14-31)

$$\begin{aligned}\dot{m}_v &= \mathsf{P}A\frac{P_{v,1}-P_{v,2}}{L}\\ &= \mathsf{P}A\frac{\phi_1 P_{\text{sat},1}-\phi_2 P_{\text{sat},2}}{L} = \mathsf{M}A(\phi_1 P_{\text{sat},1}-\phi_2 P_{\text{sat},2})\end{aligned}$$

where P is the vapor permeability and M = P/*L* is the permeance of the material, ϕ is the relative humidity and P_{sat} is the saturation pressure of water at the specified temperature. Subscripts 1 and 2 denote the air on the two sides of the wall.



Noting that the vapor pressure at the outer side of the wallboard is zero (ϕ_2 = 0) and substituting, the mass flow rate of water vapor through the wall is determined to be

$$\dot{m}_v = (2.86\times10^{-9}\ \text{kg/s.m}^2\text{.Pa})(3\times8\ \text{m}^2)[0.60(2339\ \text{Pa})-0] = 9.63\times10^{-5}\ \text{kg/s}$$

Then the total amount of moisture that flows through the wall during a 24-h period becomes

$$m_{v,24-h} = \dot{m}_v\Delta t = (9.63\times10^{-5}\ \text{kg/s})(24\times3600\ \text{s}) = \mathbf{8.32\,kg}$$

Discussion This is the maximum amount of moisture that can migrate through the wall since we assumed the vapor pressure on one side of the wall to be zero.

14-62 The inside wall of a house is finished with 9.5-mm thick gypsum wallboard with a 0.2-mm thick polyethylene film on one side. The maximum amount of water vapor that will diffuse through a 3 m × 8 m section of the wall in 24-h is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Mass transfer through the wall is one-dimensional. **3** The vapor permeabilities of the wall and of the vapor barrier are constant. **4** The vapor pressure at the outer side of the wallboard is zero.

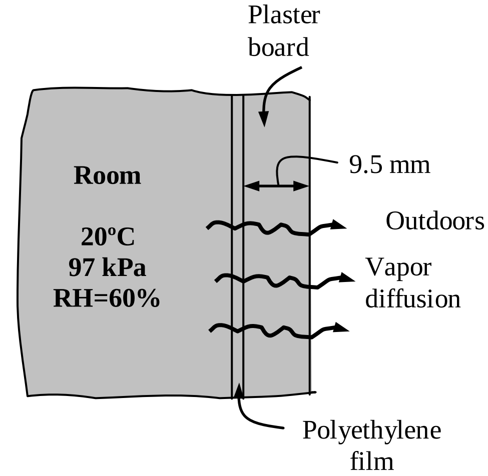
Properties The permeances of the 9.5 mm thick gypsum wall board and of the 0.2-mm thick polyethylene film are given to be 2.86×10^{-9} and 2.3×10^{-12} kg/s.m^2.Pa, respectively (Table 14-10). The saturation pressure of water at 20ºC is 2339 Pa (Table 14-9).

Analysis The mass flow rate of water vapor through a two-layer plain wall of normal area A is given as (Eqs. 14-33 and 14-35)

$$\dot{m}_v = A\frac{P_{v,1}-P_{v,2}}{R_{v,\text{total}}} = A\frac{\phi_1 P_{\text{sat},1}-\phi_2 P_{\text{sat},2}}{R_{v,\text{total}}}$$

where $R_{\text{v,total}}$ is the total vapor resistance of the medium, ϕ is the relative humidity and P_{sat} is the saturation pressure of water at the specified temperature. Subscripts 1 and 2 denote the air on the two sides of the wall. The total vapor resistance of the wallboard is

$$\begin{aligned} R_{v,\text{total}} &= R_{v,\text{wall}} + R_{v,\text{film}} \\ &= \frac{1}{2.86\times10^{-9}\ \text{kg/s.m}^2\text{.Pa}} + \frac{1}{2.3\times10^{-12}\ \text{kg/s.m}^2\text{.Pa}} \\ &= 4.35\times10^{11}\ \text{s.m}^2\text{.Pa/kg} \end{aligned}$$



Noting that the vapor pressure at the outer side of the wallboard is zero ($\phi_2 = 0$) and substituting, the mass flow rate of water vapor through the wall is determined to be

$$\dot{m}_v = A\frac{\phi_1 P_{\text{sat},1}-\phi_2 P_{\text{sat},2}}{R_{v,\text{total}}} = (3\times 8\ \text{m}^2)\frac{0.60(2339\ \text{Pa})-0}{4.35\times10^{11}\ \text{s.m}^2\text{.Pa/kg}} = 7.75\times10^{-8}\ \text{kg/s}$$

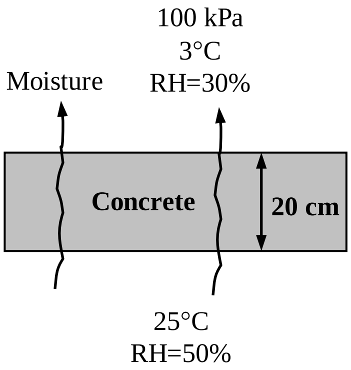
Then the total amount of moisture that flows through the wall during a 24-h period becomes

$$m_{v,24-h} = \dot{m}_v\Delta t = (7.75\times10^{-8}\ \text{kg/s})(24\times3600\ \text{s}) = \mathbf{0.00670\ kg = 6.7\ g}$$

Discussion This is the maximum amount of moisture that can migrate through the wall since we assumed the vapor pressure on one side of the wall to be zero. Note that the vapor barrier reduced the amount of vapor migration to a negligible level.

14-63 The roof of a house is made of a 20-cm thick concrete layer. The amount of water vapor that will diffuse through a 15 m × 8 m section of the roof in 24-h is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Mass transfer through the roof is one-dimensional. **3** The vapor permeability of the roof is constant.



Properties The permeability of the roof to water vapor is given to be 24.7×10^{-12} kg/s.m.Pa. The saturation pressures of water are 768 Pa at 3ºC, and 3169 Pa at 25ºC (Table 14-9).

Analysis The mass flow rate of water vapor through a plain layer of thickness *L* and normal area *A* is given as (Eq. 14-31)

$$\dot{m}_v = \mathsf{P}A\frac{P_{v,1}-P_{v,2}}{L} = \mathsf{P}A\frac{\phi_1 P_{\text{sat},1}-\phi_2 P_{\text{sat},2}}{L}$$

where P is the vapor permeability, ϕ is the relative humidity and P_{sat} is the saturation pressure of water at the specified temperature. Subscripts 1 and 2 denote the states of the air on the two sides of the roof. Substituting, the mass flow rate of water vapor through the roof is determined to be

$$\dot{m}_v = (24.7\times10^{-12}\ \text{kg/s.m.Pa})(15\times 8\ \text{m}^2)\frac{[0.50(3169\ \text{Pa})-0.30(768\ \text{Pa})]}{(0.20\ \text{m})} = 2.011\times10^{-5}\ \text{kg/s}$$

Then the total amount of moisture that flows through the roof during a 24-h period becomes

$$m_{v,24-h} = \dot{m}_v\Delta t = (2.011\times10^{-5}\ \text{kg/s})(24\times 3600\ \text{s}) = \mathbf{1.738\ kg}$$

Discussion The moisture migration through the roof can be reduced significantly by covering the roof with a vapor barrier or vapor retarder.

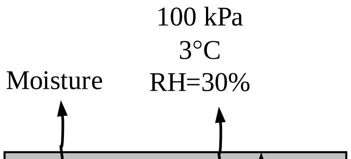
14-65 The roof of a house is made of a 20-cm thick concrete layer painted with a vapor retarder paint. The amount of water vapor that will diffuse through a 15 m × 8 m section of the roof in 24-h is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Mass transfer through the roof is one-dimensional. **3** The vapor permeabilities of the roof and of the vapor barrier are constant.

Properties The permeability of concrete to water vapor and the permeance of the vapor retarder to water vapor are given to be



24.7×10^{-12} kg/s.m.Pa and 26×10^{-12} kg/s.m^2.Pa, respectively. The saturation pressures of water are 768 Pa at 3ºC, and 3169 Pa at 25ºC (Table 14-9).

Analysis The mass flow rate of water vapor through a two-layer plain roof of normal area A is given as (Eqs. 14-33 and 14-35)

$$\dot{m}_v = A\frac{P_{v,1}-P_{v,2}}{R_{v,\text{total}}} = A\frac{\phi_1 P_{\text{sat},1}-\phi_2 P_{\text{sat},2}}{R_{v,\text{total}}}$$

where $R_{\text{v,total}}$ is the total vapor resistance of the medium, ϕ is the relative humidity and P_{sat} is the saturation pressure of water at the specified temperature. Subscripts 1 and 2 denote the air on the two sides of the roof. The total vapor resistance of the roof is

$$R_{v,\text{total}} = R_{v,\text{roof}} + R_{v,\text{film}} = \frac{L}{P}+\frac{1}{M} = \frac{0.20\text{ m}}{24.7\times10^{-12}\text{ kg/s.m.Pa}} + \frac{1}{26\times10^{-12}\text{ kg/s.m}^2\text{.Pa}}$$

$$= 4.66\times10^{10}\text{ s.m}^2\text{.Pa/kg}$$

Substituting, the mass flow rate of water vapor through the roof is determined to be

$$\dot{m}_v = A\frac{\phi_1 P_{\text{sat},1}-\phi_2 P_{\text{sat},2}}{R_{v,\text{total}}} = (15\times8\text{ m}^2)\frac{0.50(3169\text{ Pa})-0.30(768\text{ Pa})}{4.66\times10^{10}\text{ s.m}^2\text{.Pa/kg}} = 3.49\times10^{-6}\text{ kg/s}$$

Then the total amount of moisture that flows through the roof during a 24-h period becomes

$$m_{v,24-h} = \dot{m}_v\Delta t = (3.49\times10^{-6}\text{ kg/s})(24\times3600\text{ s}) = \mathbf{0.302 kg = 302\text{ g}}$$

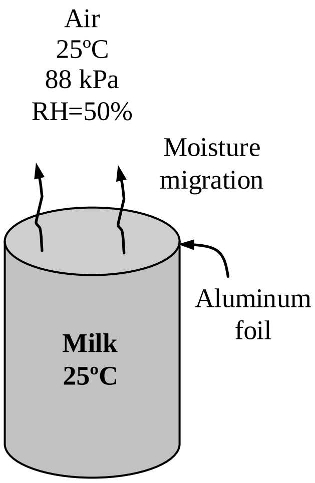
14-66 A glass of milk left on top of a counter is tightly sealed by a sheet of 0.009-mm thick aluminum foil. The drop in the level of the milk in the glass in 12 h due to vapor migration through the foil is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Mass transfer through the foil is one-dimensional. **3** The vapor permeability of the foil is constant.

Properties The permeance of the foil to water vapor is given to be 2.9×10^{-12} kg/s.m^2.Pa. The saturation pressure of water at 25ºC is 3169 Pa (Table 14-9). We take the density of milk to be 1000 kg/m^3.

Analysis The mass flow rate of water vapor through a plain layer of thickness L and normal area A is given as (Eq. 14-31)

$$\dot{m}_v = \mathsf{P}A\frac{P_{v,1}-P_{v,2}}{L} = \mathsf{P}A\frac{\phi_1 P_{\text{sat},1}-\phi_2 P_{\text{sat},2}}{L} = \mathsf{M}A(\phi_1 P_{\text{sat},1}-\phi_2 P_{\text{sat},2})$$



where P is the vapor permeability and M = P/L is the permeance of the material, ϕ is the relative humidity and P_{sat} is the saturation pressure of water at the specified temperature. Subscripts 1 and 2 denote the states of the air on the two sides of the foil.

The diffusion area of the foil is $A = \pi r^2 = \pi(0.06\text{ m}) = 0.0113\text{ m}^2$. Substituting, the mass flow rate of water vapor through the foil becomes

$$\begin{aligned}\dot{m}_v &= (2.9\times10^{-12}\text{ kg/s.m}^2\text{.Pa})(0.0113\text{ m}^2)[1(3169\text{ Pa})-0.5(768\text{ Pa})]\\ &= 5.19\times10^{-11}\text{ kg/s}\end{aligned}$$

Then the total amount of moisture that flows through the foil during a 12-h period becomes

$$m_{v,48-h} = \dot{m}_v\Delta t = (5.19\times10^{-11}\text{ kg/s})(48\times3600\text{ s}) = 8.97\times10^{-6}\text{ kg}$$

$$V = m/\rho = (8.97\times10^{-6}\text{ kg})/(1000\text{ kg/m}^3) = 8.97\times10^{-9}\text{ m}^3$$

Then the drop in the level of the milk becomes

$$\Delta h = \frac{V}{A} = \frac{8.97\times10^{-9}\text{ m}^3}{0.0113\text{ m}^2} = 7.9\times10^{-7}\text{ m} = \mathbf{0.00079\text{ mm}}$$

Discussion The drop in the level of the milk in 48 h is much less than 1 mm, and thus it is not noticeable.

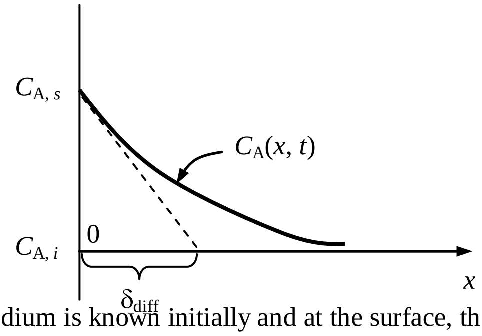
Transient Diffusion

14-67C The diffusion of a solid species into another solid of finite thickness can usually be treated as a diffusion process in a semi-infinite medium regardless of the shape and thickness of the solid since the diffusion process affects a very thin layer at the surface.

14-68C The penetration depth is defined as the location where the tangent to the concentration profile at the surface (x = 0) intercepts the $C_A = C_{A,i}$ line, and it represents the depth of diffusion at a given time. The penetration depth can be determined to be

$$\delta_{diff} = \sqrt{\pi D_{AB}\, t}$$

where D_{AB} is the diffusion coefficient and t is the time.



14-69C When the density of a species A in a semi-infinite medium is known initially and at the surface, the concentration of the species A at a specified location and time can be determined from

$$\frac{C_A(x,t)-C_{A,i}}{C_{A,s}-C_{A,i}} = \text{erfc}\left(\frac{x}{2\sqrt{D_{AB}t}}\right)$$

where $C_{A,i}$ is the initial concentration of species *A* at time $t = 0$, $C_{A,s}$ is the concentration at the inner side of the exposed surface of the medium, and erfc is the complementary error function.

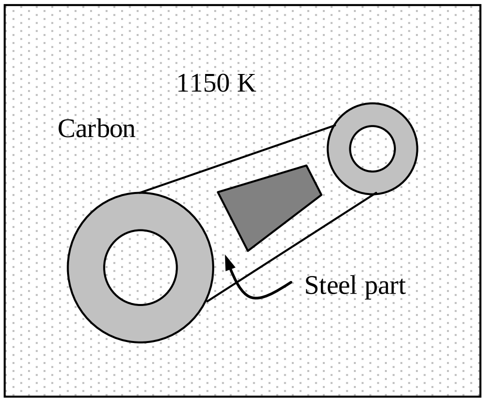
14-70 A steel component is to be surface hardened by packing it in a carbonaceous material in a furnace at 1150 K. The length of time the component should be kept in the furnace is to be determined.

Assumptions **1** Carbon penetrates into a very thin layer beneath the surface of the component, and thus the component can be modeled as a semi-infinite medium regardless of its thickness or shape. **2** The initial carbon concentration in the steel component is uniform. **3** The carbon concentration at the surface remains constant.

Properties The relevant properties are given in the problem statement.

Analysis This problem is analogous to the one-dimensional transient heat conduction problem in a semi-infinite medium with specified surface temperature, and thus can be solved accordingly. Using mass fraction for concentration since the data is given in that form, the solution can be expressed as

$$\frac{w_A(x,t)-w_{A,i}}{w_{A,s}-w_{A,i}} = \text{erfc}\left(\frac{x}{2\sqrt{D_{AB}t}}\right)$$



Substituting the specified quantities gives

$$\frac{0.0032-0.0012}{0.011-0.0012} = 0.204 = \text{erfc}\left(\frac{x}{2\sqrt{D_{AB}\,t}}\right)$$

The argument whose complementary error function is 0.204 is determined from Table 4-3 to be 0.742. That is,

$$\frac{x}{2\sqrt{D_{AB}\ t}} = 0.742$$

Then solving for the time *t* gives

$$t = \frac{x^2}{4D_{AB}(0.742)^2} = \frac{(0.0007\,\text{m})^2}{4\times(7.2\times10^{-12}\,\text{m}^2/\text{s})(0.742)^2} = 32{,}458\,\text{s} \cong \mathbf{9\,h}$$

Therefore, the steel component must be held in the furnace for 9 h to achieve the desired level of hardening.

Discussion The diffusion coefficient of carbon in steel increases exponentially with temperature, and thus this process is commonly done at high temperatures to keep the diffusion time to a reasonable level.

14-71 A steel component is to be surface hardened by packing it in a carbonaceous material in a furnace at 5000 K. The length of time the component should be kept in the furnace is to be determined.

Assumptions **1** Carbon penetrates into a very thin layer beneath the surface of the component, and thus the component can be modeled as a semi-infinite medium regardless of its thickness or shape. **2** The initial carbon concentration in the steel component is uniform. **3** The carbon concentration at the surface remains constant.

Properties The relevant properties are given in the problem statement.

Analysis This problem is analogous to the one-dimensional transient heat conduction problem in a semi-infinite medium with specified surface temperature, and thus can be solved accordingly. Using mass fraction for concentration since the data is given in that form, the solution can be expressed as

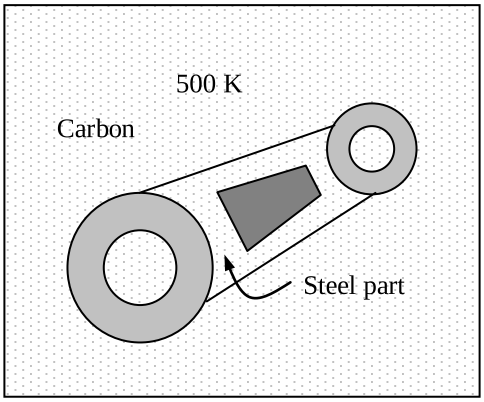
$$\frac{w_A(x,t)-w_{A,i}}{w_{A,s}-w_{A,i}}=\operatorname{erfc}\left(\frac{x}{2\sqrt{D_{AB}t}}\right)$$

Substituting the specified quantities gives

$$\frac{0.0032-0.0012}{0.011-0.0012}=0.204=\operatorname{erfc}\left(\frac{x}{2\sqrt{D_{AB}t}}\right)$$

The argument whose complementary error function is 0.204 is determined from Table 4-3 to be 0.742. That is,

$$\frac{x}{2\sqrt{D_{AB}\,t}}=0.742$$



Solving for the time t gives

$$t=\frac{x^2}{4D_{AB}(0.742)^2}=\frac{(0.0007\,\text{m})^2}{4\times(2.1\times10^{-20}\ \text{m}^2/\text{s})(0.742)^2}=\mathbf{1.06\times10^{13}\ s = 336{,}000\ years}$$

Therefore, the steel component must be held in the furnace forever to achieve the desired level of hardening.

Discussion The diffusion coefficient of carbon in steel increases exponentially with temperature, and thus this process is commonly done at high temperatures to keep the diffusion time to a reasonable level.

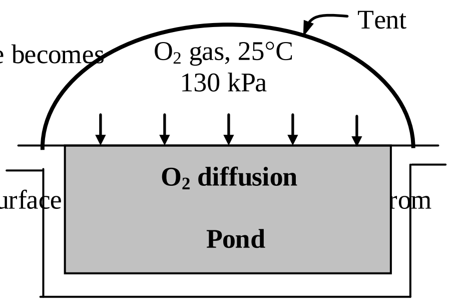
14-72 A pond is to be oxygenated by forming a tent over the water surface and filling the tent with oxygen gas. The molar concentration of oxygen at a depth of 2 cm from the surface after 12 h is to be determined.

Assumptions **1** The oxygen in the tent is saturated with water vapor. **2** Oxygen penetrates into a thin layer at the pond surface, and thus the pond can be modeled as a semi-infinite medium. **3** Both the water vapor and oxygen are ideal gases. **4** The initial oxygen content of the pond is zero.

Properties The diffusion coefficient of oxygen in water at 25ºC is D_{AB} = 2.4 $\times 10^{-9}$ m^2/s (Table 14-3a). Henry's constant for oxygen dissolved in water at 300 K (≅ 25ºC) is given in Table 14-6 to be H = 43,600 bar. The saturation pressure of water at 25ºC is 3.2 kPa (Table 14-9).

Analysis This problem is analogous to the one-dimensional transient heat conduction problem in a semi-infinite medium with specified surface temperature, and thus can be solved accordingly. The vapor pressure in the tent is the saturation pressure of water at 25ºC since the oxygen in the tent is saturated, and thus the partial pressure of oxygen in the tank is

$$P_{O_2} = P - P_v = 130 - 3.17 = 126.83 \text{ kPa}$$



Then the mole fraction of oxygen in the water at the pond surface becomes

$$y_{O_2,\text{liquid side}}(0) = \frac{P_{O_2,\text{gas side}}(0)}{H} = \frac{1.2683 \text{ bar}}{43{,}600 \text{ bar}} = 2.91 \times 10^{-5}$$

The molar concentration of oxygen at a depth of 2 cm from the surface rom

$$\frac{y_{O_2}(x,t) - y_{O_2,i}}{y_{O_2,s} - y_{O_2,i}} = \operatorname{erfc}\left(\frac{x}{2\sqrt{D_{AB}t}}\right)$$

Substituting,

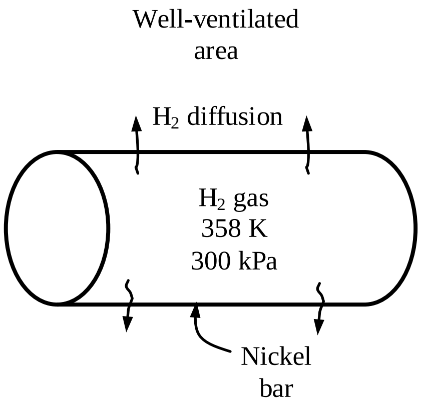
$$\frac{y_{O_2}(x,t) - 0}{2.88 \times 10^{-5} - 0} = \operatorname{erfc}\left(\frac{0.02\text{m}}{2\sqrt{(2.4 \times 10^{-9} \text{ m}^2/\text{s})(12 \times 3600\text{s})}}\right) \longrightarrow y_{O_2}(0.02\text{m}, 12\text{h}) = \mathbf{4.77 \times 10^{-6}}$$

Therefore, there will be 4.77 moles of oxygen per million at a depth of 2 cm from the surface in 12 h.

14-73 A long cylindrical nickel bar saturated with hydrogen is taken into an area that is free of hydrogen. The length of time for the hydrogen concentration at the center of the bar to drop by half is to be determined.

Assumptions **1** The bar can be treated as an infinitely long cylinder since it is very long and there is symmetry about the centerline. **2** The initial hydrogen concentration in the steel bar is uniform. **3** The hydrogen concentration at the surface remains constant at zero at all times. **4** The Fourier number is $\tau > 0.2$ so that the one-term transient solutions are valid.

Properties The molar mass of hydrogen H_2 is M = 2 kg / kmol (Table A-1). The solubility of hydrogen in nickel at 358 K is 0.00901 kmol / m^3.bar (Table 14-7). The diffusion coefficient of hydrogen in nickel at 358 K is $D_{AB} = 1.2\times10^{-12}$ m^2/s (Table 14-3b).



Analysis This problem is analogous to the one-dimensional transient heat conduction problem in an infinitely long cylinder with specified surface temperature, and thus can be solved accordingly. Noting that 300 kPa = 3 bar, the molar density of hydrogen in the nickel bar before it is taken out of the storage room is

$$\begin{aligned} C_{\mathrm{H_2,solid side}}(0) &= S \times P_{\mathrm{H_2,gas side}} \\ &= (0.00901\,\mathrm{kmol/m^3.bar})(3\,\mathrm{bar}) \\ &= 0.027\,\mathrm{kmol/m^3} \end{aligned}$$

The molar concentration of hydrogen at the center of the bar can be calculated from

$$\frac{C_{\mathrm{H_2},o} - C_{\mathrm{H_2},\infty}}{C_{\mathrm{H_2},i} - C_{\mathrm{H_2},\infty}} = A_1 e^{-\lambda_1^2 \tau}$$

The Biot number in this case can be taken to be infinity since the bar is in a well-ventilated area during the transient case. The constants A_1 and λ_1 for the infinite Bi are determined from Table 4-1 to be 1.6021 and 2.4048, respectively. Noting that the concentration of hydrogen at the outer surface is zero, and the concentration of hydrogen at the center of the bar is one half of the initial concentration, the Fourier number, τ, can be determined from

$$\frac{(0.027/2)-0}{0.027-0} = 1.6021 e^{-(2.4048)^2 \tau} \longrightarrow \tau = 0.2014$$

Using the definition of the Fourier number, the time required to drop the concentration of hydrogen by half is determined to be

$$\tau = \frac{D_{AB}\,t}{r_o^{\,2}} \longrightarrow t = \frac{\tau r_o^{\,2}}{D_{AB}} = \frac{(0.2014)(0.025)^2}{1.2\times10^{-12}} = 1.049\times10^8\ \mathrm{s} = 1214\,\mathrm{days} = \mathbf{3.33\,years}$$

Therefore, it will take years for this nickel bar to be free of hydrogen.

Diffusion in a Moving Medium

14-74C The **mass-average velocity** of a medium at some location is the average velocity of the mass at that location relative to an external reference point. It is the velocity that would be measured by a velocity sensor such as a pitot tube, a turbine device, or a hot wire anemometer inserted into the flow. The **diffusion velocity** at a location is the average velocity of a group of molecules at that location moving under the influence of concentration gradient. A **stationary medium** is a medium whose mass average velocity is zero. A **moving medium** is a medium that involves a bulk fluid motion caused by an external force.

14-75C The **diffusion velocity** at a location is the average velocity of a group of molecules at that location moving under the influence of concentration gradient. The average velocity of a species in a moving medium is equal to the sum of the bulk flow velocity and the diffusion velocity. Therefore, the diffusion velocity can increase of decrease the average velocity, depending on the direction of diffusion relative to the direction of bulk flow. The velocity of a species in the moving medium relative to a fixed reference point **will be zero** when the diffusion velocity of the species and the bulk flow velocity are equal in magnitude and opposite in direction.

14-76 C The **mass-average velocity** of a medium at some location is the average velocity of the mass at that location relative to an external reference point. The **molar-average velocity** of a medium at some location is the average velocity of the molecules at that location, regardless of their mass, relative to an external reference point. If one of these velocities are zero, the other will not necessarily be zero. The mass-average and molar-average velocities of a binary mixture will be the same when the molar masses of the two constituents are equal to each other. The mass and mole fractions of each species in this case will be the same.

14-77C (*a*) T, (*b*) T, (*c*) F, (*d*) F

14-78C The diffusion of a vapor through a stationary gas column is called the **Stefan flow**. The **Stefan's law** can be expressed as

$$\bar{j}_A = \dot{N}_A / A = \frac{C D_{AB}}{L} \ln \frac{1 - y_{A,L}}{1 - y_{A,o}}$$

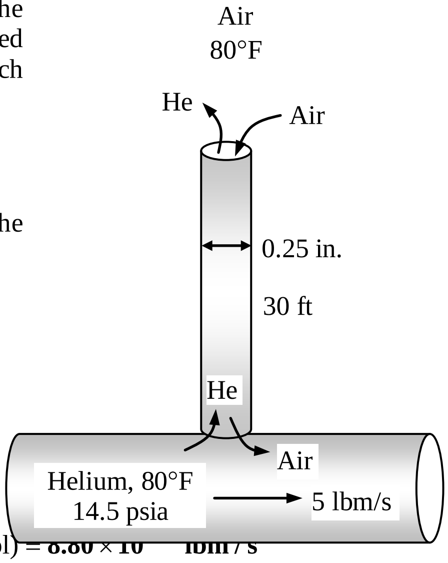
where C is the average concentration of the mixture, D_{AB} is the diffusion coefficient of A in B, L is the height of the gas column, $y_{A,\,L}$ is the molar concentration of a species at $x = L$, and $y_{A,\,o}$ is the molar concentration of the species A at $x = L$.

14-79E The pressure in a helium pipeline is maintained constant by venting to the atmosphere through a long tube. The mass flow rates of helium and air, and the net flow velocity at the bottom of the tube are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Helium and atmospheric air are ideal gases. **3** No chemical reactions occur in the tube. **4** Air concentration in the pipeline and helium concentration in the atmosphere are negligible so that the mole fraction of the helium is 1 in the pipeline, and 0 in the atmosphere (we will check this assumption later).

Properties The diffusion coefficient of helium in air (or air in helium) at normal atmospheric conditions is $D_{AB} = 7.75 \times 10^{-4}$ ft^3/s (Table 14-2). The molar mass of helium is M = 4 lbm / lbmol, and the molar mass of air is 29 lbm / lbmol (Table A-1E).

Analysis This is a typical equimolar counterdiffusion process since the problem involves two large reservoirs of ideal gas mixtures connected to each other by a channel, and the concentrations of species in each reservoir (the pipeline and the atmosphere) remain constant.



(*a*) The flow area, which is the cross-sectional area of the tube, is

$$A = \pi D^2/4 = \pi(0.25/12 \text{ ft})^2/4 = 3.41\times 10^{-4} \text{ ft}^2$$

Noting that the pressure of helium is 14.5 psia at the bottom of the tube (x = 0) and 0 at the top (x = L), its molar flow rate is

$$\dot{N}_{\text{helium}} = \dot{N}_{\text{diff,A}} = \frac{D_{AB}A}{R_u T}\frac{P_{A,0}-P_{A,L}}{L}$$

$$= \frac{(7.75\times 10^{-4} \text{ ft}^2\text{/s})(3.41\times 10^{-4} \text{ ft}^2)}{(10.73 \text{ psia.ft}^3\text{/lbmol.R})(540 \text{ R})}\frac{(14.5-0) \text{ psia}}{30 \text{ ft}}$$

$$= 2.20\times 10^{-11} \text{ lbmol/s}$$

Therefore, the mass flow rate of helium through the tube is

$$\dot{m}_{\text{helium}} = (\dot{N}M)_{\text{helium}} = (2.20\times 10^{-11} \text{ lbmol/s})(4 \text{ lbm/lbmol}) = \mathbf{8.80\times 10} \quad \mathbf{lbm/s}$$

which corresponds to 0.00278 lbm per year.

(*b*) Noting that $\dot{N}_B = -\dot{N}_A$ during an equimolar counterdiffusion process, the molar flow rate of air into the helium pipeline is equal to the molar flow rate of helium. Thus the mass flow rate of air into the pipeline is

$$\dot{m}_{\text{air}} = (\dot{N}M)_{\text{air}} = (-2.20\times 10^{-11} \text{ lbmol/s})(29 \text{ lbm/lbmol}) = \mathbf{-6.38\times 10^{-10}\ lbm/s}$$

The mass fraction of air in helium pipeline is

$$w_{\text{air}} = \frac{|\dot{m}_{\text{air}}|}{\dot{m}_{\text{total}}} = \frac{6.38\times 10^{-11} \text{ lbm/s}}{(5+6.38\times 10^{-10}) \text{ lbm/s}} = 1.28\times 10^{-10} \approx 0$$

which validates our original assumption of negligible air in the pipeline.

(*c*) The net mass flow rate through the tube is

$$\dot{m}_{net} = \dot{m}_{helium} + \dot{m}_{air} = 8.80\times 10^{-11} - 6.38\times 10^{-10} = -5.50\times 10^{-10} \text{ lbm/s}$$

The mass fraction of air at the bottom of the tube is very small, as shown above, and thus the density of the mixture at x = 0 can simply be taken to be the density of helium which is

$$\rho \cong \rho_{\text{helium}} = \frac{P}{RT} = \frac{14.5 \text{ psia}}{(2.6805 \text{ psia.ft}^3\text{/lbm.R})(540 \text{ R})} = 0.01002 \text{ lbm/ft}^3$$

Then the average flow velocity at the bottom part of the tube becomes

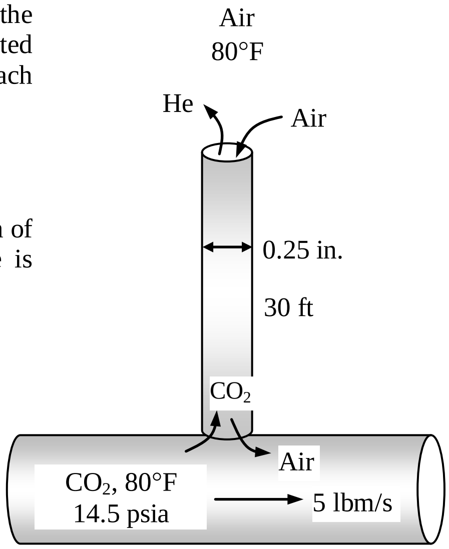
$$V = \frac{\dot{m}_{net}}{\rho A} = \frac{-5.50\times 10^{-10} \text{ lbm/s}}{(0.01002 \text{ lbm/ft}^3)(3.41\times 10^{-4} \text{ ft}^2)} = \mathbf{-1.61\times 10^{-4}\ ft/s}$$

Discussion This flow rate is difficult to measure by even the most sensitive velocity measurement devices. The negative sign indicates flow in the negative x direction (towards the pipeline).

14-80E The pressure in a carbon dioxide pipeline is maintained constant by venting to the atmosphere through a long tube. The mass flow rates of carbon dioxide and air, and the net flow velocity at the bottom of the tube are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Carbon dioxide and atmospheric air are ideal gases. **3** No chemical reactions occur in the tube. **4** Air concentration in the pipeline and carbon dioxide concentration in the atmosphere are negligible so that the mole fraction of the carbon dioxide is 1 in the pipeline, and 0 in the atmosphere (we will check this assumption later).

Properties The diffusion coefficient of carbon dioxide in air (or air in carbon dioxide) at normal atmospheric conditions is $D_{AB} = 1.72\times10^{-4}$ ft²/s (Table 14-2). The molar mass of carbon dioxide is M = 4 lbm / lbmol, and the molar mass of air is 29 lbm / lbmol (Table A-1E).



Analysis This is a typical equimolar counterdiffusion process since the problem involves two large reservoirs of ideal gas mixtures connected to each other by a channel, and the concentrations of species in each reservoir (the pipeline and the atmosphere) remain constant.

(*a*) The flow area, which is the cross-sectional area of the tube, is

$$A = \pi D^2/4 = \pi(0.25/12\ \text{ft})^2/4 = 3.41\times10^{-4}\ \text{ft}^2$$

Noting that the pressure of carbon dioxide is 14.5 psia at the bottom of the tube (x = 0) and 0 at the top (x = L), its molar flow rate is determined from Eq. 14-64 to be

$$\begin{aligned}\dot N_{\text{helium}} &= \dot N_{\text{diff,A}} = \frac{D_{AB}A}{R_uT}\frac{P_{A,0}-P_{A,L}}{L}\\ &= \frac{(1.72\times10^{-4}\ \text{ft}^2/\text{s})(3.41\times10^{-4}\ \text{ft}^2)}{(10.73\,\text{psia.ft}^3/\text{lbmol.R})(540\ \text{R})}\frac{(14.5-0)\ \text{psia}}{30\ \text{ft}}\\ &= 4.89\times10^{-12}\ \text{lbmol/s}\end{aligned}$$

Therefore, the mass flow rate of carbon dioxide through the tube is

$$\dot m_{CO_2} = (\dot N M)_{CO_2} = (4.89\times10^{-12}\ \text{lbmol/s})(44\ \text{lbm/lbmol}) = \mathbf{2.15\times10^{-10}\ lbm/s}$$

which corresponds to 0.00678 lbm per year.

(*b*) Noting that $\dot N_B = -\dot N_A$ during an equimolar counter diffusion process, the molar flow rate of air into the CO_2 pipeline is equal to the molar flow rate of CO_2. Thus the mass flow rate of air into the pipeline is

$$\dot m_{\text{air}} = (\dot N M)_{\text{air}} = (-4.89\times10^{-12}\ \text{lbmol/s})(29\ \text{lbm/lbmol}) = \mathbf{-1.42\times10^{-10}\ lbm/s}$$

The mass fraction of air in carbon dioxide pipeline is

$$w_{\text{air}} = \frac{|\dot m_{\text{air}}|}{\dot m_{\text{total}}} = \frac{1.42\times10^{-10}\ \text{lbm/s}}{(5+1.42\times10^{-10})\ \text{lbm/s}} = 2.84\times10^{-11} \approx 0$$

which validates our original assumption of negligible air in the pipeline.

(*c*) The net mass flow rate through the tube is

$$\dot m_{net} = \dot m_{CO_2} + \dot m_{air} = 2.15\times10^{-10} - 1.42\times10^{-10} = -7.3\times10^{-11}\ \text{lbm/s}$$

The mass fraction of air at the bottom of the tube is very small, as shown above, and thus the density of the mixture at $x = 0$ can simply be taken to be the density of carbon dioxide which is

$$\rho \cong \rho_{CO_2} = \frac{P}{RT} = \frac{14.5\ \text{psia}}{(0.2438\ \text{psia.ft}^3/\text{lbm.R})(540\ \text{R})} = 0.110\ \text{lbm/ft}^3$$

Then the average flow velocity at the bottom part of the tube becomes

$$\text{V} = \frac{\dot m_{\text{net}}}{\rho A} = \frac{-7.30\times10^{-11}\ \text{lbm/s}}{(0.110\,\text{lbm/ft}^3)(3.41\times10^{-4}\ \text{ft}^2)} = \mathbf{-1.95\times10^{-6}\ ft/s}$$

Discussion This flow rate is difficult to measure by even the most sensitive velocity measurement devices. The negative sign indicates flow in the negative x direction (towards the pipeline).

14-81 A hydrogen tank is maintained at atmospheric temperature and pressure by venting to the atmosphere through the charging valve. The initial mass flow rate of hydrogen out of the tank is to be determined.

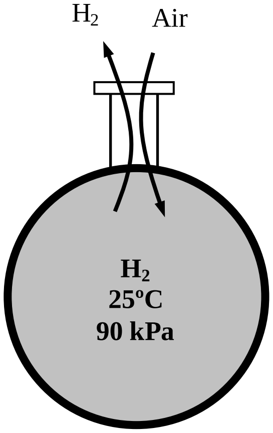
Assumptions **1** Steady operating conditions at initial conditions exist. **2** Hydrogen and atmospheric air are ideal gases. **3** No chemical reactions occur in the valve. **4** Air concentration in the tank and hydrogen concentration in the atmosphere are negligible so that the mole fraction of the hydrogen is 1 in the tank, and 0 in the atmosphere (we will check this assumption later).

Properties The molar mass of hydrogen is M = 2 kg/kmol (Table A-1). The diffusion coefficient of hydrogen in air (or air in hydrogen) at 1 atm and 25ºC is $D_{\text{AB}} = 7.2\times10^{-5}$ m^3/s (Table 14-2). However, the pressure in the tank is 90 kPa = 0.88 atm. The diffusion coefficient at 25ºC and 0.88 atm is determined from

$$D_{AB} = \frac{D_{AB,\text{1 atm}}}{P\,(\text{in atm})} = \frac{7.2\times10^{-5}}{0.88} = 8.11\times10^{-5}\,\text{m}^2/\text{s}$$

Analysis This is a typical equimolar counterdiffusion process since the problem involves two large reservoirs of ideal gas mixtures connected to each other by a channel, and the concentrations of species in each reservoir (the pipeline and the atmosphere) remain constant. The cross-sectional area of the valve is

$$A = \pi D^2/4 = \pi(0.03\text{m})^2/4 = 7.069\times10^{-4}\ \text{m}^2$$



Noting that the pressure of hydrogen is 90 kPa at the bottom of the charging valve (x = 0) and 0 kPa at the top (x = L), its molar flow rate is determined from Eq. 14-64 to be

$$\begin{aligned}\dot{N}_{\text{H}_2} &= \dot{N}_{diff,A} = \frac{D_{AB}A}{R_uT}\frac{P_{A,0}-P_{A,L}}{L}\\ &= \frac{(8.11\times10^{-5}\ \text{m}^2/\text{s})(7.069\times10^{-4}\ \text{m}^2)}{(8.314\ \text{kPa.m}^3/\text{kmol.K})(298\,\text{K})}\frac{(90-0)\text{kPa}}{0.1\,\text{m}}\\ &= 2.081\times10^{-8}\ \text{kmol/s}\end{aligned}$$

Then the mass flow rate of hydrogen becomes

$$\dot{m}_{\text{H}_2} = \left(\dot{N}M\right)_{\text{H}_2} = \left(2.081\times10^{-8}\ \text{kmol/s}\right)\left(2\,\text{kg/kmol}\right) = \mathbf{4.2\times10^{-8}\ kg/s}$$

Discussion This is the highest mass flow rate. It will decrease during the process as air diffuses into the tank and the concentration of hydrogen in tank drops.

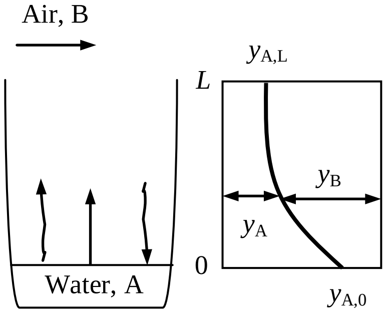
14-83E The amount of water that evaporates from a Stefan tube at a specified temperature and pressure over a specified time period is measured. The diffusion coefficient of water vapor in air is to be determined.

Assumptions **1** Water vapor and atmospheric air are ideal gases. **2** The amount of air dissolved in liquid water is negligible. **3** Heat is transferred to the water from the surroundings to make up for the latent heat of vaporization so that the temperature of water remains constant at 70°F.

Properties The saturation pressure of water at 70°F is 0.3632 psia (Table A-9E).

Analysis The vapor pressure at the air-water interface is the saturation pressure of water at 70°F, and the mole fraction of water vapor (species A) is determined from

$$y_{\text{vapor,o}} = y_{A,o} = \frac{P_{\text{vapor,o}}}{P} = \frac{0.3632\text{ psia}}{13.8\text{ psia}} = 0.0263$$



Dry air is blown on top of the tube and thus $y_{\text{vapor},L} = y_{A,L} = 0$. Also, the total molar density throughout the tube remains constant because of the constant temperature and pressure conditions, and is determined to be

$$C = \frac{P}{R_u T} = \frac{13.8\,\text{psia}}{(10.73\text{psia.ft}^3/\text{lbmol}\cdot\text{R})(530\text{R})} = 2.42\,\text{lbmol/ft}^3$$

The cross-sectional area of the valve is

$$A = \pi D^2/4 = \pi(1/12\,\text{ft})^2/4 = 5.45\times10^{-3}\,\text{ft}^2$$

The evaporation rate is given to be 0.0015 lbm per 10 days. Then the molar flow rate of vapor is determined to be

$$\dot{N}_A = \dot{N}_{\text{vapor}} = \frac{m_{\text{vapor}}}{M_{\text{vapor}}} = \frac{0.0015\,\text{lbm}}{(10\times24\times3600\,\text{s})(18\,\text{lbm/lbmol})} = 9.65\times10^{-11}\,\text{lbm/s}$$

Finally, substituting the information above into Eq. 14-59 we get

$$\frac{\dot{N}_A}{A} = \frac{CD_{AB}}{L}\ln\left(\frac{1-y_{A,L}}{1-y_{A,o}}\right) \longrightarrow \frac{9.65\times10^{-11}\,\text{lbm/s}}{5.45\times10^{-3}\,\text{ft}^2} = \frac{(2.42\,\text{lbm/ft}^3)D_{\text{AB}}}{10/12\,\text{ft}}\ln\left(\frac{1-0}{1-0.0263}\right)$$

It gives

$$D_{\text{AB}} = \mathbf{2.29\times10^{-7}\ ft^2/s}$$

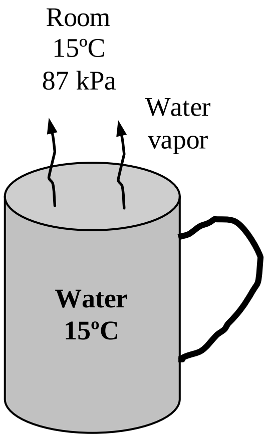
for the binary diffusion coefficient of water vapor in air at 70°F and 13.8 psia.

14-84 A pitcher that is half filled with water is left in a room with its top open. The time it takes for the entire water in the pitcher to evaporate is to be determined.

Assumptions **1** Water vapor and atmospheric air are ideal gases. **2** The amount of air dissolved in liquid water is negligible. **3** Heat is transferred to the water from the surroundings to make up for the latent heat of vaporization so that the temperature of water remains constant at 15°C.

Properties The saturation pressure of water at 15°C is 1.705 kPa (Table A-9). The density of water in the pitcher can be taken to be 1000 kg/m³. The diffusion coefficient of water vapor in air at 15ºC (= 288 K) and 87 kPa (0.86 atm) can be determined from

$$D_{AB} = 1.87\times10^{-10}\frac{T^{2.072}}{P} = 1.87\times10^{-10}\frac{(288\text{ K})^{2.072}}{0.86} = 2.71\times10^{-5}\text{ m}^2/\text{s}$$



Analysis The flow area, which is the cross-sectional area of the pitcher, is

$$A = \pi D^2/4 = \pi(0.08\text{ m})^2/4 = 5.026\times10^{-3}\text{ m}^2$$

The vapor pressure at the air-water interface is the saturation pressure of water at 15ºC, which is 1.705 kPa. The air at the top of the pitcher ($x = L$) can be assumed to be dry ($P_{A,L}$=0). The distance between the water surface and the top of the pitcher is initially 15 cm, and will be 30 cm at the end of the process when all the water is evaporated. Therefore, we can take the average height of the air column above the water surface to be (15+30)/2 = 22.5 cm. Then the molar flow rate is determined from

$$\dot{N}_A = \frac{D_{AB}A}{R_uT}\left(\frac{P_{A,o}-P_{A,L}}{L}\right) = \frac{(2.71\times10^{-5}\text{ m}^2/\text{s})(5.026\times10^{-3}\text{ m}^2)}{(8.314\text{ kPa.m}^3/\text{kmol.K})(288\text{K})}\frac{(1.7051-0)\text{ kPa}}{0.225\text{ m}}$$
$$= 4.31\times10^{-10}\text{ kmol/s}$$

The initial mass of water in the pitcher is

$$m_{water} = \rho\frac{\pi D^2}{4}L = (1000\text{ kg/m}^3)\frac{\pi(0.08\text{ m})^2}{4}(0.15\text{ m}) = 0.754\text{ kg}$$

Then the time required to evaporate the water completely becomes

$$\dot{N}_{\text{vapor}} = \frac{m_{\text{vapor}}}{\Delta t\times M_{\text{vapor}}}$$

$$\Delta t = \frac{m_{\text{vapor}}}{\dot{N}_{\text{vapor}}\times M_{\text{vapor}}} = \frac{0.754\text{ kg}}{(4.31\times10^{-10}\text{ kmol/s})(18\text{ kg/kmol})} = \mathbf{97{,}190{,}000\,s}$$

which is equivalent to 1125 days. Therefore, it will take the water in the pitcher about 3 years to evaporate completely.

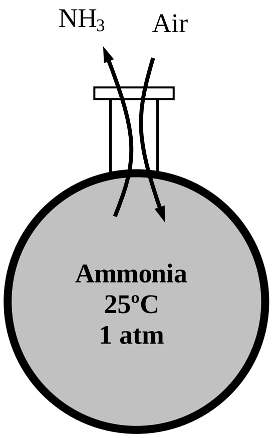
14-85 A large ammonia tank is vented to the atmosphere. The rate of loss of ammonia and the rate of air infiltration into the tank are to be determined.

Assumptions **1** Ammonia vapor and atmospheric air are ideal gases. **2** The amount of air dissolved in liquid ammonia is negligible. **3** Heat is transferred to the ammonia from the surroundings to make up for the latent heat of vaporization so that the temperature of ammonia remains constant at 25°C.

Properties The molar mass of ammonia is M = 17 kg/kmol, and the molar mass of air is M = 29 kg/kmol (Table A-1). The diffusion coefficient of ammonia in air (or air in ammonia) at 1 atm and 25ºC is $D_{\text{AB}} = 7.2 \times 10^{-5}$ m^2/s (Table 14-2).

Analysis This is a typical equimolar counterdiffusion process since the problem involves two large reservoirs of ideal gas mixtures connected to each other by a channel, and the concentrations of species in each reservoir (the tank and the atmosphere) remain constant. The flow area, which is the cross-sectional area of the tube, is

$$A = \pi D^2/4 = \pi(0.01\text{m})^2/4 = 7.86\times10^{-5}\ \text{m}^2$$



Noting that the pressure of ammonia is 1 atm = 101.3 kPa at the bottom of the tube (x = 0) and 0 at the top ($x = L$), its molar flow rate is determined from Eq. 14-64 to be

$$\dot{N}_{\text{ammonia}} = \dot{N}_{\text{diff,A}} = \frac{D_{AB}A}{R_u T}\frac{P_{A,o} - P_{A,L}}{L}$$

$$= \frac{(2.6\times10^{-5}\ \text{m}^2\text{/s})(7.86\times10^{-5}\ \text{m}^2)}{(8.314\ \text{kPa}\cdot\text{m}^3\text{/kmol}\cdot\text{K})(298\text{K})}\frac{(101.3-0)\text{kPa}}{3\text{m}}$$

$$= \mathbf{2.78\times10^{-11}\ kmol/s}$$

Therefore, the mass flow rate of ammonia through the tube is

$$\dot{m}_{\text{NH}_3} = (\dot{N}M)_{\text{NH}_3} = (2.78\times10^{-11}\ \text{kmol/s})(17\ \text{kg/kmol}) = \mathbf{4.73\times10^{-10}\ kg/s}$$

which corresponds to 0.0149 kg per year.

Note that $\dot{N}_B = -\dot{N}_A$ during an equimolar counter diffusion process. Therefore, the molar flow rate of air into the ammonia tank is equal to the molar flow rate of ammonia out of the tank. Then the mass flow rate of air into the pipeline becomes

$$\dot{m}_{\text{air}} = (\dot{N}M)_{\text{air}} = (-2.78\times10^{-11}\ \text{kmol/s})(29\ \text{kg/kmol}) = \mathbf{-8.06\times10^{-10}\ kg/s}$$

Mass Convection

14-86C Mass convection is expressed on a mass basis in an analogous manner to heat transfer as

$$\dot{m}_{\text{conv}} = h_{\text{mass}} A_s (\rho_{A,s} - \rho_{A,\infty})$$

where h_{mass} is the average mass transfer coefficient in m / s, A_s is the surface area in m^2, and $\rho_{A,s}$ and $\rho_{A,\infty}$ are the densities of species A at the surface (on the fluid side) and the free stream, respectively.

14-87C The region of the fluid near the surface in which concentration gradients exist is called the **concentration boundary layer**. In **flow over a plate**, the thickness of the concentration boundary layer δ_c for a species A at a specified location on the surface is defined as the normal distance y from the surface at which

$$\frac{\rho_{A,s} - \rho_A}{\rho_{A,s} - \rho_\infty} = 0.99$$

where $\rho_{A,s}$ and $\rho_{A,\infty}$ are the densities of species A at the surface (on the fluid side) and the free stream, respectively.

14-88C The dimensionless **Schmidt number** is defined as the ratio of momentum diffusivity to mass diffusivity $\text{Sc} = \nu / D_{AB}$, and it represents the relative magnitudes of momentum and mass diffusion at molecular level in the velocity and concentration boundary layers, respectively. The Schmidt number corresponds to the *Prandtl number* in heat transfer. A Schmidt number of *unity* indicates that momentum and mass transfer by diffusion are comparable, and velocity and concentration boundary layers almost coincide with each other.

14-89C The dimensionless **Sherwood number** is defined as $\text{Sh} = h_{\text{mass}} L / D_{AB}$ where L is the characteristic length, h_{mass} is the mass transfer coefficient and D_{AB} is the mass diffusivity. The Sherwood number represents the effectiveness of mass convection at the surface, and serves as the dimensionless mass transfer coefficient. The Sherwood number corresponds to the *Nusselt number* in heat transfer. A Sherwood number of unity for a plain fluid layer indicates mass transfer by pure diffusion in a fluid.

14-90C The dimensionless **Lewis number** is defined as the ratio of thermal diffusivity to mass diffusivity $(\text{Le} = \alpha / D_{AB})$, and it represents the relative magnitudes of heat and mass diffusion at molecular level in the thermal and concentration boundary layers, respectively. A Lewis number of unity indicates that heat and mass diffuse at the same rate, and the thermal and concentration boundary layers coincide.

14-91C Yes, the Grasshof number evaluated using density difference instead of temperature difference can also be used in natural convection heat transfer calculations. In natural convection heat transfer, the term $\Delta\rho / \rho$ is replaced by $\beta\Delta T$ for convenience in calculations.

14-92C Using the analogy between heat and mass transfer, the mass transfer coefficient can be determined from the relations for heat transfer coefficient using the **Chilton-Colburn Analogy** expressed as

$$\frac{h_{\text{heat}}}{h_{\text{mass}}} = \rho C_p \left(\frac{\text{Sc}}{\text{Pr}}\right)^{2/3} = \rho C_p \left(\frac{\alpha}{D_{AB}}\right)^{2/3} = \rho C_p \text{Le}^{2/3}$$

Once the heat transfer coefficient h_{heat} is available, the mass transfer coefficient h_{heat} can be obtained from the relation above by substituting the values of the properties.

14-93C The molar mass of gasoline (C_8H_{18}) is 114 kg/kmol, which is much larger than the molar mass of air, which is 29 kg/kmol. Therefore, the gasoline vapor will settle down instead of rising even if it is at a much higher temperature than the surrounding air. As a result, the warm mixture of air and gasoline on top of an open gasoline will most likely settle down instead of rising in a cooler environment

14-94C Of the two identical cups of coffee, the one with no sugar will cool much faster than the one with plenty of sugar at the bottom. This is because in the case of no sugar, the coffee at the top will cool relatively fast and it will settle down while the warmer coffee at the bottom will rise to the top and cool off. When there is plenty of sugar at the bottom, however, the warmer coffee at the bottom will be heavier and thus it will not rise to the top. The elimination of natural convection currents and limiting heat transfer in water to conduction only will slow down the heat loss from the coffee considerably. In solar ponds, the rise of warm water at the bottom to the top is prevented by planting salt to the bottom of the pond.

14-95C The normalized velocity, thermal, and concentration boundary layers coincide during flow over a plate when the molecular diffusivity of momentum, heat, and mass are identical. That is, $\nu = \alpha = D_{AB}$ or Pr = Sc = Le = 1.

14-96C The relation $f\,\text{Re} / 2 = \text{Nu} = \text{Sh}$ is known as the **Reynolds analogy**. It is valid under the conditions that the Prandtl, Schmidt, and Lewis numbers are equal to units. That is, $\nu = \alpha = D_{AB}$ or Pr = Sc = Le = 1. Reynolds analogy enables us to determine the seemingly unrelated friction, heat transfer, and mass transfer coefficients when only one of them is known or measured.

14-97C The relation $f / 2 = \text{St Pr}^{2/3} = \text{St}_{mass}\text{Sc}^{2/3}$ is known as the **Chilton-Colburn analogy**. Here St is the Stanton number, Pr is the Prandtl number, St_{mass} is the Stanton number in mass transfer, and Sc is the Schmidt number. The relation is valid for $0.6 < \text{Pr} < 60$ and $0.6 < \text{Sc} < 3000$. Its importance in engineering is that Chilton-Colburn analogy enables us to determine the seemingly unrelated friction, heat transfer, and mass transfer coefficients when only one of them is known or measured.

14-98C The relation $h_{heat} = \rho\, C_p\, h_{mass}$ is the result of the Lewis number Le = 1, and is known as the **Lewis relation**. It is valid for air-water vapor mixtures in the temperature range encountered in heating and air-conditioning applications. The Lewis relation is commonly used in air-conditioning practice. It asserts that the wet-bulb and adiabatic saturation temperatures of moist air are nearly identical. The Lewis relation can be used for heat and mass transfer in turbulent flow even when the Lewis number is not unity.

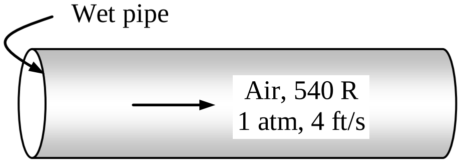
14-99C A convection mass transfer is referred to as the **low mass flux** when the flow rate of species undergoing mass flow is low relative to the total flow rate of the liquid or gas mixture so that the mass transfer between the fluid and the surface does not affect the *flow velocity*. The evaporation of water into air from lakes, rivers, etc. can be treated as a low mass-flux process since the mass fraction of water vapor in the air in such cases is just a few percent.

14-100E The liquid layer on the inner surface of a circular pipe is dried by blowing air through it. The mass transfer coefficient is to be determined.

Assumptions **1** The low mass flux model and thus the analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 540 R). **2** The flow is fully developed.

Properties Because of low mass flux conditions, we can use dry air properties for the mixture at the specified temperature of 540 R and 1 atm, for which $\nu = 0.17 \times 10^{-3}\ \text{ft}^2/\text{s}$ (Table A-15E). The mass diffusivity of water vapor in air at 540 R is determined from Eq. 14-15 to be

$$
\begin{aligned}
D_{AB} = D_{\text{H}_2\text{O-air}} &= 1.87 \times 10^{-10} \frac{T^{2.072}}{P} \\
&= 1.87 \times 10^{-10} \frac{(540/1.8)^{2.072}}{1} = 2.54 \times 10^{-5}\ \text{m}^2/\text{s} \\
&= 2.73 \times 10^{-4}\ \text{ft}^2/\text{s}
\end{aligned}
$$



The Reynolds number of the flow is

$$
\text{Re} = \frac{\text{V}D}{\nu} = \frac{(4\ \text{ft/s})(0.5/12\ \text{ft})}{0.17 \times 10^{-3}\ \text{ft}^2/\text{s}} = 980
$$

which is less than 2300 and thus the flow is laminar. Therefore, based on the analogy between heat and mass transfer, the Nusselt and the Sherwood numbers in this case are Nu = Sh = 3.66. Using the definition of Sherwood number, the mass transfer coefficient is determined to be

$$
h_{\text{mass}} = \frac{\text{Sh}\, D_{AB}}{D} = \frac{(3.66)(2.73 \times 10^{-4}\ \text{ft}^2/\text{s})}{0.5/12\ \text{ft}} = \mathbf{0.024\ ft/s}
$$

Discussion The mass transfer rate (or the evaporation rate) in this case can be determined by defining logarithmic mean concentration difference in an analogous manner to the logarithmic mean temperature difference.

14-101 Air is blown over a body covered with a layer of naphthalene, and the rate of sublimation is measured. The heat transfer coefficient under the same flow conditions over the same geometry is to be determined.

Assumptions **1** The concentration of naphthalene in the air is very small, and the low mass flux conditions exist so that the Chilton-Colburn analogy between heat and mass transfer is applicable (will be verified). **2** Both air and naphthalene vapor are ideal gases.

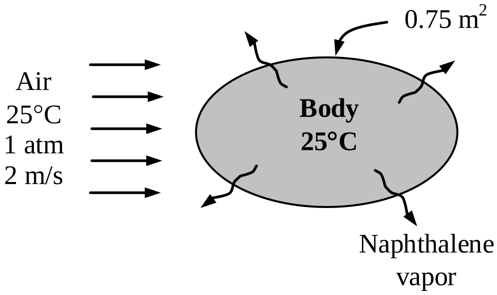
Properties The molar mass of naphthalene is 128.2 kg/kmol. Because of low mass flux conditions, we can use dry air properties for the mixture at the specified temperature of 15°C and 1 atm, at which $\rho = 1.184 \text{ kg/m}^3$, $C_p = 1007 \text{ J/kg}\cdot\text{K}$, and $\alpha = 2.141\times10^{-5} \text{ m}^2\text{/s}$ (Table A-15).

Analysis The incoming air is free of naphthalene, and thus the mass fraction of naphthalene at free stream conditions is zero, $w_{A,\infty} = 0$. Noting that the vapor pressure of naphthalene at the surface is 11 Pa, the surface mass fraction is determined to be

$$w_{A,s} = \frac{P_{A,s}}{P}\left(\frac{M_A}{M_{air}}\right) = \frac{11\text{Pa}}{101{,}325\text{Pa}}\left(\frac{128.2\,\text{kg/kmol}}{29\,\text{kg/kmol}}\right) = 4.8\times10^{-4}$$

which confirms that the low mass flux approximation is valid. The rate of evaporation of naphthalene in this case is

$$\dot{m}_{\text{evap}} = \frac{m}{\Delta t} = \frac{0.1\text{kg}}{(45\times60\text{s})} = 3.703\times10^{-5} \text{ kg/s}$$



Then the mass convection coefficient becomes

$$h_{mass} = \frac{\dot{m}}{\rho A(w_{A,s} - w_{A,\infty})} = \frac{3.703\times10^{-5} \text{ kg/s}}{(1.184\,\text{kg/m}^3)(0.75\text{m}^2)(4.8\times10^{-4} - 0)} = 0.0869\,\text{m/s}$$

Using the analogy between heat and mass transfer, the average heat transfer coefficient is determined from Eq. 14-89 to be

$$\begin{aligned} h_{\text{heat}} &= \rho C_p h_{\text{mass}}\left(\frac{\alpha}{D_{AB}}\right)^{2/3} \\ &= (1.184\,\text{kg/m}^3)(1007\,\text{J/kg.K})(0.0869\,\text{m/s})\left(\frac{2.141\times10^{-5}\text{ m}^2\text{/s}}{0.61\times10^{-5}\text{ m}^2\text{/s}}\right)^{2/3} \\ &= \mathbf{239\,W/m^2.^\circ C} \end{aligned}$$

Discussion Naphthalene has been commonly used in heat transfer studies to determine convection heat transfer coefficients because of the convenience it offers.

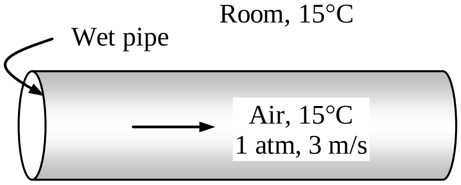
14-102 The liquid layer on the inner surface of a circular pipe is dried by blowing air through it. The mass transfer coefficient is to be determined.

Assumptions **1** The low mass flux model and thus the analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 300 K). **2** The flow is fully developed.

Properties Because of low mass flux conditions, we can use dry air properties for the mixture at the specified temperature of 15°C and 1 atm, for which $\nu = 1.47\times10^{-5}\ \text{m}^2/\text{s}$ (Table A-15). The mass diffusivity of water vapor in air at 288 K is determined from Eq. 14-15 to be

$$D_{AB} = D_{\text{H}_2\text{O-air}} = 1.87\times10^{-10}\frac{T^{2.072}}{P}$$

$$= 1.87\times10^{-10}\frac{(288\text{ K})^{2.072}}{1} = 2.33\times10^{-5}\ \text{m}^2/\text{s}$$



Analysis The Reynolds number of the flow is

$$\text{Re} = \frac{\text{V}D}{\nu} = \frac{(3\text{ m/s})(0.15\text{ m})}{1.47\times10^{-5}\ \text{m}^2/\text{s}} = 30{,}612$$

which is greater than 10,000 and thus the flow is turbulent. The Schmidt number in this case is

$$\text{Sc} = \frac{\nu}{D_{AB}} = \frac{1.47\times10^{-5}\ \text{m}^2/\text{s}}{2.33\times10^{-5}\ \text{m}^2/\text{s}} = 0.631$$

Therefore, the Sherwood number in this case is determined from Table 14-13 to be

$$\text{Sh} = 0.023\,\text{Re}^{0.8}\,\text{Sc}^{0.4} = 0.023(30{,}612)^{0.8}(0.631)^{0.4} = 74.2$$

Using the definition of Sherwood number, the mass transfer coefficient is determined to be

$$h_{mass} = \frac{\text{Sh}D_{AB}}{D} = \frac{(74.2)(2.33\times10^{-5}\ \text{m}^2/\text{s})}{0.15\text{m}} = \mathbf{0.0115\,m/s}$$

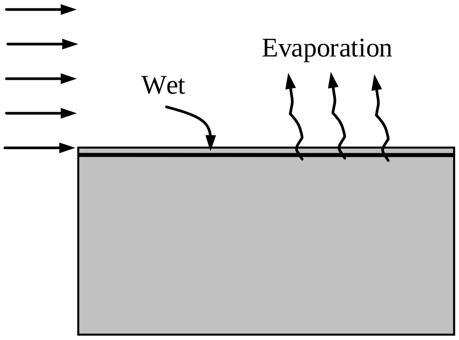
14-104 A wet flat plate is dried by blowing air over it. The mass transfer coefficient is to be determined.

Assumptions **1** The low mass flux model and thus the analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 300 K). **2** The critical Reynolds number for flow over a flat plate is 500,000.

Properties Because of low mass flux conditions, we can use dry air properties for the mixture at the specified temperature of 15°C and 92 kPa = 92/101.325 = 0.908 atm, for which (Table A-15)

$$\nu = \nu_{1\,\text{atm}} / P(\text{atm}) = (1.47\times10^{-5}\ \text{m}^2/\text{s})/0.908\ \text{atm} = 1.62\times10^{-5}\ \text{m}^2/\text{s}$$

Analysis The mass diffusivity of water vapor in air at 288 K is determined from Eq. 14-15 to be



$$\begin{aligned} D_{AB} &= D_{\text{H}_2\text{O-air}} \\ &= 1.87\times10^{-10}\,\frac{T^{2.072}}{P} \\ &= 1.87\times10^{-10}\,\frac{(288\ \text{K})^{2.072}}{0.908\ \text{atm}} \\ &= 2.57\times10^{-5}\ \text{m}^2/\text{s} \end{aligned}$$

The Reynolds number of the flow is

$$\text{Re} = \frac{VL}{\nu} = \frac{(4\ \text{m/s})(2\ \text{m})}{1.62\times10^{-5}\ \text{m}^2/\text{s}} = 493{,}827$$

which is less than 500,000, and thus the flow is laminar. The Schmidt number in this case is

$$\text{Sc} = \frac{\nu}{D_{AB}} = \frac{1.62\times10^{-5}\ \text{m}^2/\text{s}}{2.57\times10^{-5}\ \text{m}^2/\text{s}} = 0.630$$

Therefore, the Sherwood number in this case is determined from Table 14-13 to be

$$\text{Sh} = 0.664\,\text{Re}^{0.5}\,\text{Sc}^{1/3} = 0.664(493{,}827)^{0.5}(0.630)^{1/3} = 400.1$$

Using the definition of Sherwood number, the mass transfer coefficient is determined to be

$$h_{mass} = \frac{\text{Sh}D_{AB}}{L} = \frac{(400.1)(2.57\times10^{-5}\ \text{m}^2/\text{s})}{2\ \text{m}} = \mathbf{0.00514\ m/s}$$

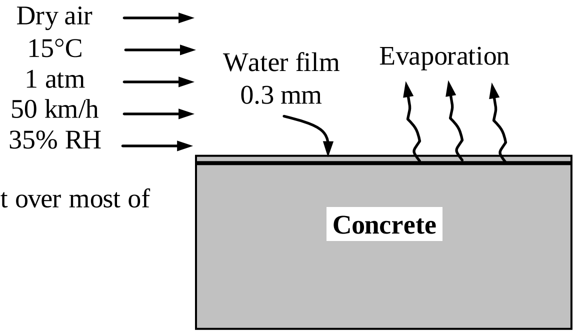
14-105 A wet concrete patio is to be dried by winds. The time it takes for the patio to dry is to be determined.

Assumptions **1** The low mass flux model and thus the analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 300 K). **2** The critical Reynolds number for flow over a flat plate is 500,000. **3** Water is at the same temperature as air.

Properties Because of low mass flux conditions, we can use dry air properties for the mixture at the specified temperature of 15ºC and 1 atm, for which $\nu = 1.47\times10^{-5}\ \text{m}^2/\text{s}$ and $\rho = 1.225\ \text{kg/m}^3$ (Table A-15). The saturation pressure of water at 15ºC is 1.705 kPa. The mass diffusivity of water vapor in air at 15ºC = 288 K is determined from Eq. 14-15 to be

$$D_{AB} = D_{\text{H}_2\text{O-air}} = 1.87\times10^{-10}\frac{T^{2.072}}{P} = 1.87\times10^{-10}\frac{(288\ \text{K})^{2.072}}{1\,\text{atm}} = 2.33\times10^{-5}\ \text{m}^2/\text{s}$$

Analysis The Reynolds number of the flow is



$$\begin{aligned}\text{Re} &= \frac{\mathrm{V}L}{\nu}\\ &= \frac{(50\ \text{km/h})(5\ \text{m})}{1.47\times10^{-5}\ \text{m}^2/\text{s}}\left(\frac{1\,\text{m/s}}{3.6\ \text{km/h}}\right)\\ &= 4.724\times10^{6}\end{aligned}$$

which is more than 500,000, and thus the flow is turbulent over most of the surface. The Schmidt number in this case is

$$\text{Sc} = \frac{\nu}{D_{AB}} = \frac{1.47\times10^{-5}\ \text{m}^2/\text{s}}{2.33\times10^{-5}\ \text{m}^2/\text{s}} = 0.631$$

Therefore, the Sherwood number in this case is determined from Table 14-13 to be

$$\text{Sh} = 0.037\,\text{Re}^{0.8}\,\text{Sc}^{1/3} = 0.037(4.724\times10^{6})^{0.8}(0.631)^{1/3} = 6934$$

Using the definition of Sherwood number, the mass transfer coefficient is determined to be

$$h_{mass} = \frac{\text{Sh}D_{AB}}{L} = \frac{(6934)(2.33\times10^{-5}\ \text{m}^2/\text{s})}{5\,\text{m}} = 0.0323\text{m/s}$$

Noting that the air at the water surface will be saturated and that the saturation pressure of water at 15ºC is 1.705 kPa, the mass fraction of water vapor in the air at the surface and at the free stream conditions are, from Eq. 14-10,

$$w_{A,s} = y_{A,s}\frac{M_A}{M} = \frac{P_{sat}}{P}\frac{M_A}{M_{air}} = \frac{(1.705\,\text{kPa})}{101.325\,\text{kPa}}\left(\frac{18\,\text{kg/kmol}}{29\,\text{kg/kmol}}\right) = 0.01044$$

$$w_{A,\infty} = y_{A,\infty}\frac{M_A}{M_{air}} = \frac{\phi P_{sat}}{P}\frac{M_A}{M_{air}} = \frac{(0.35)(1.705\,\text{kPa})}{101.325\,\text{kPa}}\left(\frac{18\,\text{kg/kmol}}{29\,\text{kg/kmol}}\right) = 0.00365$$

Then the rate of mass transfer to the air becomes

$$\begin{aligned}\dot m_{\text{evap.}} &= h_{\text{mass}}\rho A(w_{A,s} - w_{A,\infty})\\ &= (0.0323\text{m/s})(1.225\,\text{kg/m}^3)(5\text{m}\times5\,\text{m})(0.01044 - 0.003655)\\ &= 0.00671\text{kg/s}\end{aligned}$$

The total mass of water on the concrete patio is

$$m_{water} = \rho V = (1000\,\text{kg/m}^3)(5\text{m}\times5\text{m}\times0.3\times10^{-3}\,\text{m}) = 7.5\,\text{kg}$$

Then the time required to evaporate the water on the concrete patio becomes

$$\Delta t = \frac{m_{water}}{\dot m_{evap}} = \frac{7.5\,\text{kg}}{0.00671\text{kg/s}} = 1117\text{s} = \mathbf{18.6min}$$

14-106E A spherical naphthalene ball is suspended in a room where it is subjected to forced air flow. The average mass transfer coefficient between the naphthalene and the air is to be determined.

Assumptions **1** The concentration of naphthalene in the air is very small, and the low mass flux conditions exist so that the Chilton-Colburn analogy between heat and mass transfer is applicable (will be verified). **2** Both air and naphthalene vapor are ideal gases. **3** Both the ball and the room are at the same temperature.

Properties The Schmidt number of naphthalene in air at room temperature is given to be 2.35. Because of low mass flux conditions, we can use dry air properties for the mixture at the specified temperature of 80°F and 1 atm from Table A-15E,

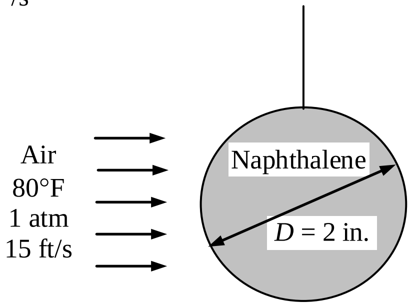
$$k = 0.015 \text{ Btu/h.ft.°F} \qquad \nu = 0.17\times10^{-3}\text{ ft}^2/\text{s}$$
$$\mu = 1.250\times10^{-5}\text{ lbm/ft.s} \qquad \text{Pr} = 0.72$$

Analysis Noting that the Schmidt number for naphthalene in air is 2.35, the mass diffusivity of naphthalene in air is determined from

$$\text{Sc} = \frac{\nu}{D_{AB}} \longrightarrow D_{AB} = \frac{\nu}{\text{Sc}} = \frac{0.17\times10^{-3}\text{ ft}^2/\text{s}}{2.35} = 7.234\times10^{-5}\text{ ft}^2/\text{s}$$

The Reynolds number of the flow is

$$\text{Re} = \frac{\text{V}D}{\nu} = \frac{(15\text{ ft/s})(2/12\text{ ft})}{(0.17\times10^{-3}\text{ ft}^2/\text{s})} = 14{,}706$$



Noting that $\mu_\infty = \mu_s$ for air in this case since the air and the ball are assumed to be at the same temperature, the Sherwood number can be determined from the forced heat convection relation for a sphere by replacing Pr by the Sc number to be

$$\text{Sh} = \frac{h_{mass}D}{D_{AB}} = 2 + \left[0.4\,\text{Re}^{1/2} + 0.06\,\text{Re}^{2/3}\right]\text{Sc}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$
$$= 2 + \left[0.4(14{,}706)^{1/2} + 0.06(14{,}706)^{2/3}\right](2.35)^{0.4} = 121$$

Then the mass transfer coefficient becomes

$$h_{mass} = \frac{\text{Sh}D_{AB}}{D} = \frac{(121)(7.234\times10^{-5}\text{ ft}^2/\text{s})}{0.166\text{ ft}} = \mathbf{0.0525\,ft/s}$$

Discussion Note that the Nusselt number relations in heat transfer can be used to determine the Sherwood number in mass transfer by replacing Prandtl number by the Schmidt number.

14-107 A raindrop is falling freely in atmospheric air. The terminal velocity of the raindrop at which the drag force equals the weight of the drop and the average mass transfer coefficient are to be determined.

Assumptions **1** The low mass flux model and thus the analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 300 K). **2** The raindrop is spherical in shape. **3** The reduction in the diameter of the raindrop due to evaporation when the terminal velocity is reached is negligible.

Properties Because of low mass flux conditions, we can use dry air properties for the mixture. The properties of air at 1 atm and the free-stream temperature of 25ºC (and the dynamic viscosity at the surface temperature of 9ºC) are (Table A-15)

$$\rho = 1.184 \text{ kg/m}^3 \qquad \mu_\infty = 1.849\times10^{-5} \text{ kg/m.s}$$

$$\upsilon = 1.562\times10^{-5} \text{ m}^2\text{/s} \qquad \mu_{s,@\,282\text{ K}} = 1.759\times10^{-5} \text{ kg/m.s}$$

At 1 atm and the film temperature of (25+9)/2 = 17ºC = 290 K, the kinematic viscosity of air is, from Table A-11, $\nu = 1.488\times10^{-5} \text{ m}^2\text{/s}$, while the mass diffusivity of water vapor in air is, Eq. 14-15,

$$D_{AB} = D_{\text{H}_2\text{O-air}} = 1.87\times10^{-10}\frac{T^{2.072}}{P} = 1.87\times10^{-10}\frac{(290\text{ K})^{2.072}}{1\text{ atm}} = 2.37\times10^{-5}\text{ m}^2\text{ / s}$$

Analysis The weight of the raindrop before any evaporation occurs is

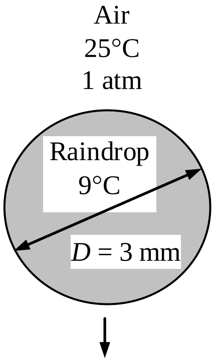
$$F_D = mg = \rho V g = (1000\text{ kg/m}^3)\left[\frac{\pi(0.003\text{ m})^3}{6}\right](9.8\text{ m/s}^2) = 1.38\times10^{-4}\text{ N}$$

The drag force is determined from $F_D = C_D A_N \dfrac{\rho u_\infty^{\;2}}{2}$ where drag coefficient C_D is to be determined using Fig. 10-20 which requires the Reynolds number. Since we do not know the velocity we cannot determine the Reynolds number. Therefore, the solution requires a trial-error approach. We choose a velocity and perform calculations to obtain the drag force. After a couple trial we choose a velocity of 8 m/s. Then the Reynolds number becomes

$$\text{Re} = \frac{\mathbf{V}_\infty D}{\upsilon} = \frac{(8\text{ m/s})(0.003\text{ m})}{1.562\times10^{-5}\text{ m}^2\text{/s}} = 1536$$

The corresponding drag coefficient from Fig. 10-20 is 0.5. Then,

$$F_D = C_D A_N\frac{\rho u_\infty^{\;2}}{2} = (0.5)\left[\frac{\pi(0.003\text{ m})^2}{4}\right]\frac{(1.184\text{ kg/m}^3)(8\text{ m/s})^2}{2} = 1.34\times10^{-4}$$



which is sufficiently close to the value calculated before. Therefore, the terminal velocity of the raindrop is ***V*** **= 8 m/s.** The Schmidt number is

$$\text{Sc} = \frac{\nu}{D_{\text{AB}}} = \frac{1.488\times10^{-5}\text{ m}^2\text{/s}}{2.37\times10^{-5}\text{ m}^2\text{/s}} = 0.628$$

Then the Sherwood number can be determined from the forced heat convection relation for a sphere by replacing Pr by the Sc number to be

$$\text{Sh} = \frac{h_{mass}D}{D_{AB}} = 2 + \left[0.4\,\text{Re}^{1/2} + 0.06\,\text{Re}^{2/3}\right]\text{Sc}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2 + \left[0.4(1536)^{1/2} + 0.06(1536)^{2/3}\right](0.628)^{0.4}\left(\frac{1.849\times10^{-5}}{1.759\times10^{-5}}\right)^{1/4} = 21.9$$

Then the mass transfer coefficient becomes

$$h_{\text{mass}} = \frac{\text{Sh}D_{AB}}{D} = \frac{(21.9)(2.37\times10^{-5}\text{ m}^2\text{/s})}{0.003\text{m}} = \mathbf{0.173\ m/s}$$

14-108 Wet steel plates are to be dried by blowing air parallel to their surfaces. The rate of evaporation from both sides of a plate is to be determined.

Assumptions **1** The low mass flux model and thus the analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 300 K). **2** The critical Reynolds number for flow over a flat plate is 500,000. **3** The plates are far enough from each other so that they can be treated as flat plates. **4** The air is dry so that the amount of moisture in the air is negligible.

Properties The molar masses of air and water are M = 29 and M = 18 kg/kmol, respectively (Table A-1). Because of low mass flux conditions, we can use dry air properties for the mixture. The properties of the air at 1 atm and at the film temperature of (20 + 25) = 22.5ºC are (Table A-15)

$\nu = 1.539\times10^{-5}\ \text{m}^2/\text{s}$ $C_p = 1007\ \text{J / kg K}$

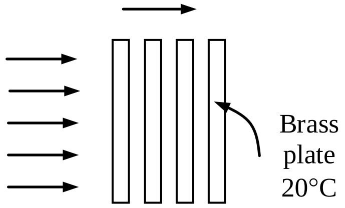
$\rho = 1.194\ \text{kg /m}^3$ $\text{Pr} = 0.7303$

The saturation pressure of water at 20ºC is 2.339 kPa (Table A-9). The mass diffusivity of water vapor in air at 22.5ºC = 295.5 K is determined from Eq. 14-15 to be

$$D_{AB} = D_{\text{H}_2\text{O-air}} = 1.87\times10^{-10}\frac{T^{2.072}}{P} = 1.87\times10^{-10}\frac{(295.5\text{K})^{2.072}}{1\text{atm}} = 2.46\times10^{-5}\ \text{m}^2/\text{s}$$

Analysis The Reynolds number for flow over the flat plate is

$$\text{Re} = \frac{VL}{\nu} = \frac{(4\ \text{m/s})(0.4\ \text{m})}{1.539\times10^{-5}\ \text{m}^2/\text{s}} = 103{,}964$$



which is less than 500,000, and thus the air flow is laminar over the entire plate. The Schmidt number in this case is

$$\text{Sc} = \frac{\nu}{D_{AB}} = \frac{1.539\times10^{-5}\ \text{m}^2/\text{s}}{2.46\times10^{-5}\ \text{m}^2/\text{s}} = 0.626$$

Therefore, the Sherwood number in this case is determined from Table 14-13 to be

$$\text{Sh} = 0.664\ \text{Re}_L^{0.5}\text{Sc}^{1/3} = 0.664(103{,}964)^{0.5}(0.626)^{1/3} = 183.1$$

Using the definition of Sherwood number, the mass transfer coefficient is determined to be

$$h_{\text{mass}} = \frac{\text{Sh}D_{AB}}{L} = \frac{(183.1)(2.46\times10^{-5}\ \text{m}^2/\text{s})}{0.4\text{m}} = 0.0113\text{m/s}$$

Noting that the air at the water surface will be saturated and that the saturation pressure of water at 20ºC is 2.339 kPa, the mass fraction of water vapor in the air at the surface of the plate is, from Eq. 14-10,

$$w_{A,s} = y_{A,s}\frac{M_A}{M} = \frac{P_{sat}}{P}\frac{M_A}{M_{air}} = \frac{(2.339\text{kPa})}{101.325\text{kPa}}\left(\frac{18\text{kg/kmol}}{29\text{kg/kmol}}\right) = 0.01433$$

and $w_{A,\infty} = 0$

Then the rate of mass transfer to the air becomes

$$\begin{aligned}\dot{m}_{\text{evap.}} &= h_{\text{mass}}\rho A(w_{A,s} - w_{A,\infty})\\ &= (0.0113\text{m/s})(1.194\text{kg/m}^3)(2\times0.4\text{m}\times0.4\text{m})(0.01433-0)\\ &= \mathbf{6.19\times10^{-5}kg/s}\end{aligned}$$

Discussion This is the upper limit for the evaporation rate since the air is assumed to be completely dry.

14-109E Air is blown over a square pan filled with water. The rate of evaporation of water and the rate of heat transfer to the pan to maintain the water temperature constant are to be determined.

Assumptions **1** The low mass flux model and thus the analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 80°F). **2** The critical Reynolds number for flow over a flat plate is 500,000. **3** Water is at the same temperature as the air.

Properties The molar masses of air and water are $M = 29$ and $M = 18$ lbm/lbmol, respectively (Table A-1E). Because of low mass flux conditions, we can use dry air properties for the mixture at the specified temperature of 80°F and 1 atm, for which $\nu = 0.17 \times 10^{-3}$ ft^2/s, and $\rho = 0.074$ lbm/ft^3 (Table A-15E). The saturation pressure of water at 80ºF is 0.5073 psia, and the heat of vaporization is 1048 Btu/lbm. The mass diffusivity of water vapor in air at 80ºF = 540 R = 300 K is determined from Eq. 14-15 to be

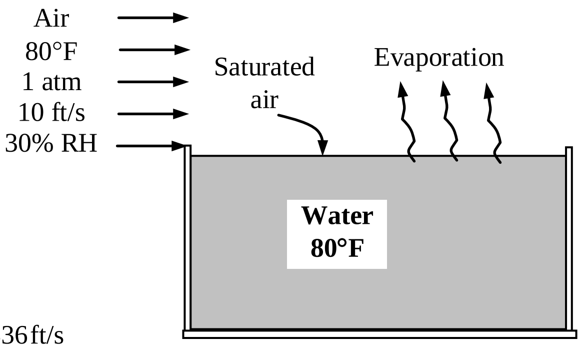
$$D_{AB} = D_{\text{H}_2\text{O-air}} = 1.87\times10^{-10}\frac{T^{2.072}}{P} = 1.87\times10^{-10}\frac{(300\,\text{K})^{2.072}}{1\text{atm}} = 2.54\times10^{-5}\ \text{m}^2/\text{s} = 2.74\times10^{-4}\ \text{ft}^2/\text{s}$$

Analysis The Reynolds number for flow over the free surface is

$$\text{Re} = \frac{VL}{\nu} = \frac{(10\text{ft/s})(15/12\text{ ft})}{0.17\times10^{-3}\ \text{ft}^2/\text{s}} = 73{,}530$$

which is less than 500,000, and thus the flow is laminar over the entire surface. The Schmidt number in this case is

$$\text{Sc} = \frac{\nu}{D_{AB}} = \frac{0.17\times10^{-3}\ \text{ft}^2/\text{s}}{2.734\times10^{-4}\ \text{ft}^2/\text{s}} = 0.622$$



Therefore, the Sherwood number in this case is determined from Table 14-13 to be

$$\text{Sh} = 0.664\,\text{Re}_\text{L}{}^{0.5}\text{Sc}^{1/3} = 0.664(73{,}530)^{0.5}(0.622)^{1/3} = 153.7$$

Using the definition of Sherwood number, the mass transfer coefficient is determined to be

$$h_\text{mass} = \frac{\text{Sh}D_{AB}}{L} = \frac{(153.7)(2.734\times10^{-4}\ \text{ft}^2/\text{s})}{15/12\,\text{ft}} = 0.0336\,\text{ft/s}$$

Noting that the air at the water surface will be saturated and that the saturation pressure of water at 80ºF is 0.5073 psia (= 0.0345 atm), the mass fraction of water vapor in the air at the surface and at the free stream conditions are, from Eq. 14-10,

$$w_{A,s} = y_{A,s}\frac{M_A}{M} = \frac{P_{sat}}{P}\frac{M_A}{M_{air}} = \frac{(0.3)(0.5073\,\text{psia})}{14.7\,\text{psia}}\left(\frac{18\text{lbm/lbmol}}{29\text{lbm/lbmol}}\right) = 0.00643$$

$$w_{A,\infty} = y_{A,\infty}\frac{M_A}{M_{air}} = \frac{\phi P_{sat}}{P}\frac{M_A}{M_{air}} = \frac{(1.0)(0.5073\,\text{psia})}{14.7\,\text{psia}}\left(\frac{18\text{lbm/lbmol}}{29\text{lbm/lbmol}}\right) = 0.02142$$

Then the rate of mass transfer to the air becomes

$$\dot{m}_\text{evap} = h_\text{mass}\rho A_s(w_{A,s} - w_{A,\infty}) = (0.0336\,\text{ft/s})(0.074\,\text{lbm/ft}^3)(15/12\text{ft}^2)(0.02142 - 0.00642) = \mathbf{5.83\times10^{-5}\ lbm/s}$$

Noting that the latent heat of vaporization of water at 80ºF is h_{fg} = 1048 Btu/ lbm, the required rate of heat supply to the water to maintain its temperature constant is

$$\dot{Q} = \dot{m}_{evap.}\,h_{fg} = (5.83\times10^{-5}\ \text{lbm/s})(1048\ \text{Btu/lbm}) = \mathbf{0.0611\ Btu/s = 220\ Btu/h}$$

Discussion If no heat is supplied to the pan, the heat of vaporization of water will come from the water, and thus the water temperature will have to drop below the air temperature.

14-110E Air is blown over a square pan filled with water. The rate of evaporation of water and the rate of heat transfer to the pan to maintain the water temperature constant are to be determined.

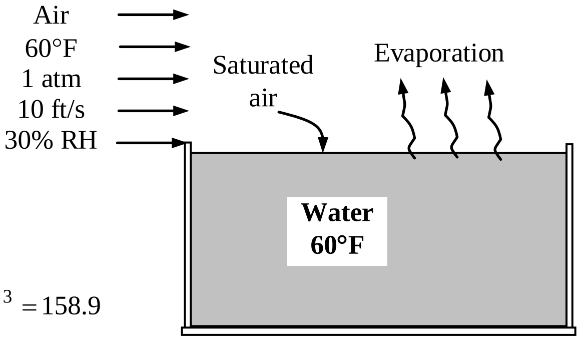
Assumptions **1** The low mass flux model and thus the analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 60°F). **2** The critical Reynolds number for flow over a flat plate is 500,000. **3** Water is at the same temperature as air.

Properties The molar masses of air and water are M = 29 and M = 18 lbm/lbmol, respectively (Table A-1E). Because of low mass flux conditions, we can use dry air properties for the mixture at the specified temperature of 60°F and 1 atm, for which $\nu = 0.159\times10^{-3}$ ft^2/s, and $\rho = 0.076$ lbm / ft^3 (Table A-15E). The saturation pressure of water at 60ºF is 0.2563 psia, and the heat of vaporization is 1060 Btu/lbm. The mass diffusivity of water vapor in air at 60ºF = 520 R = 288.9 K is determined from Eq. 14-15 to be

$$D_{AB} = D_{\mathrm{H_2O\text{-}air}} = 1.87\times10^{-10}\frac{T^{2.072}}{P} = 1.87\times10^{-10}\frac{(288.9\,\mathrm{K})^{2.072}}{1\mathrm{atm}} = 2.35\times10^{-5}\ \mathrm{m^2/s} = 2.53\times10^{-4}\ \mathrm{ft^2/s}$$

Analysis The Reynolds number for flow over the free surface is

$$\mathrm{Re} = \frac{VL}{\nu} = \frac{(10\mathrm{ft/s})(15/12\ \mathrm{ft})}{0.159\times10^{-3}\ \mathrm{ft^2/s}} = 78{,}620$$



which is less than 500,000, and thus the flow is laminar over the entire surface. The Schmidt number in this case is

$$\mathrm{Sc} = \frac{\nu}{D_{AB}} = \frac{0.159\times10^{-3}\ \mathrm{ft^2/s}}{2.53\times10^{-4}\ \mathrm{ft^2/s}} = 0.628$$

Therefore, the Sherwood number in this case is determined from Table 14-13 to be

$$\mathrm{Sh} = 0.664\,\mathrm{Re_L}^{0.5}\mathrm{Sc}^{1/3} = 0.664(78{,}620)^{0.5}(0.622)^{1/3} = 158.9$$

Using the definition of Sherwood number, the mass transfer coefficient is determined to be

$$h_{\mathrm{mass}} = \frac{\mathrm{Sh}D_{AB}}{L} = \frac{(158.9)(2.53\times10^{-4}\ \mathrm{ft^2/s})}{15/12\mathrm{ft}} = 0.0322\mathrm{ft/s}$$

Noting that the air at the water surface will be saturated and that the saturation pressure of water at 60ºF is 0.2563 psia, the mass fraction of water vapor in the air at the surface and at the free stream conditions are, from Eq. 14-10,

$$w_{A,s} = y_{A,s}\frac{M_A}{M} = \frac{P_{sat}}{P}\frac{M_A}{M_{air}} = \frac{(0.3)(0.2563\,\mathrm{psia})}{14.7\mathrm{psia}}\left(\frac{18\mathrm{lbm/lbmol}}{29\mathrm{lbm/lbmol}}\right) = 0.00325$$

$$w_{A,\infty} = y_{A,\infty}\frac{M_A}{M_{air}} = \frac{\phi P_{sat}}{P}\frac{M_A}{M_{air}} = \frac{(1.0)(0.2565\,\mathrm{psia})}{14.7\mathrm{psia}}\left(\frac{18\mathrm{lbm/lbmol}}{29\mathrm{lbm/lbmol}}\right) = 0.01082$$

Then the rate of mass transfer to the air becomes

$$\dot{m}_{\mathrm{evap}} = h_{\mathrm{mass}}\rho A(w_{A,s} - w_{A,\infty}) = (0.0322\,\mathrm{ft/s})(0.076\mathrm{lbm/ft^3})(15/12\mathrm{ft^3})(0.01082 - 0.00325) = \mathbf{2.35\times10^{-5}\ lbm/s}$$

Noting that the latent heat of vaporization of water at 60ºF is h_{fg} = 1060 Btu/ lbm, the required rate of heat supply to the water to maintain its temperature constant is

$$\dot{Q} = \dot{m}_{\mathrm{evap}}h_{fg} = (2.35\times10^{-5}\ \mathrm{lbm/s})(1060\ \mathrm{Btu/lbm}) = \mathbf{0.0249\ Btu/s = 89.5\ Btu/h}$$

Discussion If no heat is supplied to the pan, the heat of vaporization of water will come from the water, and thus the water temperature will have to drop below the air temperature.

Simultaneous Heat and Mass Transfer

14-111C In steady operation, the mass transfer process does not have to involve heat transfer. However, a mass transfer process that involves phase change (evaporation, sublimation, condensation, melting etc.) must involve heat transfer. For example, the evaporation of water from a lake into air (mass transfer) requires the transfer of latent heat of water at a specified temperature to the liquid water at the surface (heat transfer).

14-112C It is possible for a shallow body of water to freeze during a cool and dry night even when the ambient air and surrounding surface temperatures never drop to 0°C. This is because when the air is not saturated (ϕ < 100 percent), there will be a difference between the concentration of water vapor at the water-air interface (which is always saturated) and some distance above it. Concentration difference is the driving force for mass transfer, and thus this concentration difference will drive the water into the air. But the water must vaporize first, and it must absorb the latent heat of vaporization from the water. The temperature of water near the surface must drop as a result of the sensible heat loss, possibly below the freezing point.

14-113C During evaporation from a water body to air, the latent heat of vaporization will be equal to *convection* heat transfer from the air when *conduction* from the lower parts of the water body to the surface is negligible, and temperature of the surrounding surfaces is at about the temperature of the water surface so that the *radiation* heat transfer is negligible.

14-114 Air is blown over a jug made of porous clay to cool it by simultaneous heat and mass transfer. The temperature of the water in the jug when steady conditions are reached is to be determined.

Assumptions **1** The low mass flux conditions exist so that the Chilton-Colburn analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 300 K). **2** Both air and water vapor at specified conditions are ideal gases (the error involved in this assumption is less than 1 percent). **3** Radiation effects are negligible.

Properties Because of low mass flux conditions, we can use dry air properties for the mixture at the average temperature of $(T_\infty + T_s)/2$ which cannot be determined at this point because of the unknown surface temperature T_s. We know that $T_s < T_\infty$ and, for the purpose of property evaluation, we take T_s to be 20°C. Then, the properties of water at 20°C and the properties of dry air at the average temperature of 25°C and 1 atm are (Tables A-9 and A-15)

$$\text{Water at 20°C: } h_{fg} = 2454 \text{ kJ/kg}, \; P_v = 2.34 \text{ kPa. Also, at 30°C, } P_{sat\,@\,30°\text{C}} = 4.25 \text{ kPa}$$

$$\text{Dry air at 25°C: } C_p = 1.007 \text{ kJ/kg}\cdot°\text{C}, \; \alpha = 2.141\times10^{-5} \text{ m}^2\text{/s}$$

Also, the mass diffusivity of water vapor in air at 25°C is $D_{\text{H}_2\text{O-air}} = 2.50\times10^{-5} \text{ m}^2/\text{s}$ (Table 14-4), and the molar masses of water and air are 18 and 29 kg/kmol, respectively (Table A-1).

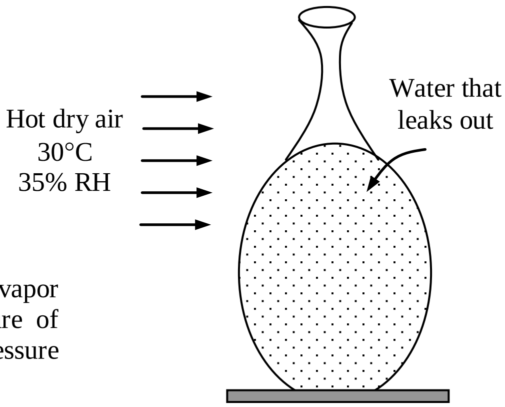
Analysis The surface temperature of the jug can be determined by rearranging Chilton-Colburn equation as

$$T_s = T_\infty - \frac{h_{fg}}{C_p \text{Le}^{2/3}} \frac{M_v}{M} \frac{P_{v,s} - P_{v,\infty}}{P}$$

where the Lewis number is

$$\text{Le} = \frac{\alpha}{D_{AB}} = \frac{2.141\times10^{-5} \text{ m}^2\text{/s}}{2.50\times10^{-5} \text{ m}^2\text{/s}} = 0.856$$

Note that we could take the Lewis number to be 1 for simplicity, but we chose to incorporate it for better accuracy.



The air at the surface is saturated, and thus the vapor pressure at the surface is simply the saturation pressure of water at the surface temperature (2.34 kPa). The vapor pressure of air far from the surface is determined from

$$P_{v,\infty} = \phi P_{\text{sat@}T_\infty} = (0.35) P_{\text{sat@30°C}} = (0.35)(4.25 \text{ kPa}) = 1.488 \text{ kPa}$$

Noting that the atmospheric pressure is 1 atm = 101.3 Pa, substituting the known quantities gives

$$T_s = 30°\text{C} - \frac{2454 \text{ kJ/kg}}{(1.007 \text{ kJ/kg.°C})(0.856)^{2/3}} \frac{18 \text{ kg/kmol}}{29 \text{ kg/kmol}} \frac{(2.34 - 1.488) \text{ kPa}}{101.3 \text{ kPa}} = \mathbf{15.9°C}$$

Therefore, the temperature of the drink can be lowered to 15.9°C by this process.

Discussion The accuracy of this result can be improved by repeating the calculations with dry air properties evaluated at (30+16)/2 = 18°C and water properties at 16.0°C. But the improvement will be minor.

14-116E In a hot summer day, a bottle of drink is to be cooled by wrapping it in a wet cloth, and blowing air to it. The temperature of the drink in the bottle when steady conditions are reached is to be determined.

Assumptions **1** The low mass flux conditions exist so that the Chilton-Colburn analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 80°F). **2** Both air and water vapor at specified conditions are ideal gases (the error involved in this assumption is less than 1 percent). **3** Radiation effects are negligible.

Properties Because of low mass flux conditions, we can use dry air properties for the mixture at the average temperature of $(T_\infty + T_s)/2$ which cannot be determined at this point because of the unknown surface temperature T_s. We know that $T_s < T_\infty$ and, for the purpose of property evaluation, we take T_s to be 60°F. Then the properties of water at 60°F and the properties of dry air at the average temperature of (60+80)/2 = 70°F and 1 atm are (Tables A-9E and A-15E)

$$\text{Water at 60°F}: \ h_{fg} = 1060 \text{ Btu/lbm}, \ P_v = 0.2563 \text{ psia. Also, at 80°F}, P_{sat\,@\,80°\text{F}} = 0.5073 \text{ psia}$$

$$\text{Dry air at 70°F}: \ C_p = 0.24 \text{ Btu/lbm}\cdot°\text{F}, \ \alpha = 0.8093 \text{ ft}^2/\text{h} = 2.25\times10^{-4} \text{ ft}^2/\text{s}$$

Also, the molar masses of water and air are 18 and 29 lbm/lbmol, respectively (Table A-1E), and the mass diffusivity of water vapor in air at 80°F (= 294.4 K) is

$$D_{AB} = D_{\text{H}_2\text{O-air}} = 1.87\times10^{-10}\frac{T^{2.072}}{P} = 1.87\times10^{-10}\frac{(294.4\text{K})^{2.072}}{1\text{atm}} = 2.44\times10^{-5} \text{ m²/s} = 2.63\times10^{-4} \text{ ft²/s}$$

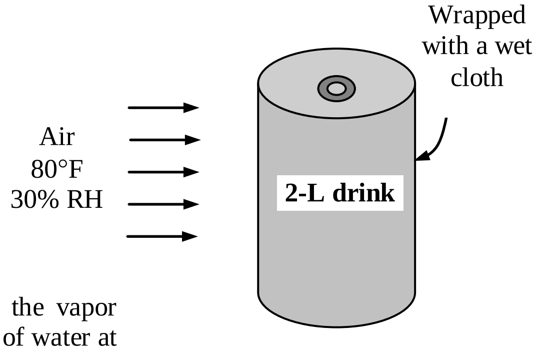
Analysis The surface temperature of the jug can be determined by rearranging Chilton-Colburn equation as

$$T_s = T_\infty - \frac{h_{fg}}{C_p \text{Le}^{2/3}}\frac{M_v}{M}\frac{P_{v,s} - P_{v,\infty}}{P}$$

where the Lewis number is

$$\text{Le} = \frac{\alpha}{D_{AB}} = \frac{2.25\times10^{-4} \text{ ft}^2/\text{s}}{2.63\times10^{-4} \text{ ft}^2/\text{s}} = 0.856$$

Note that we could take the Lewis number to be 1 for simplicity, but we chose to incorporate it for better accuracy.



The air at the surface is saturated, and thus the vapor pressure at the surface is simply the saturation pressure of water at the surface temperature (0.2563 psia). The vapor pressure of air far from the surface is determined from

$$P_{v,\infty} = \phi P_{\text{sat}@T_\infty} = (0.3)P_{\text{sat}@80°\text{F}} = (0.3)(0.5073 \text{ psia}) = 0.152 \text{ psia}$$

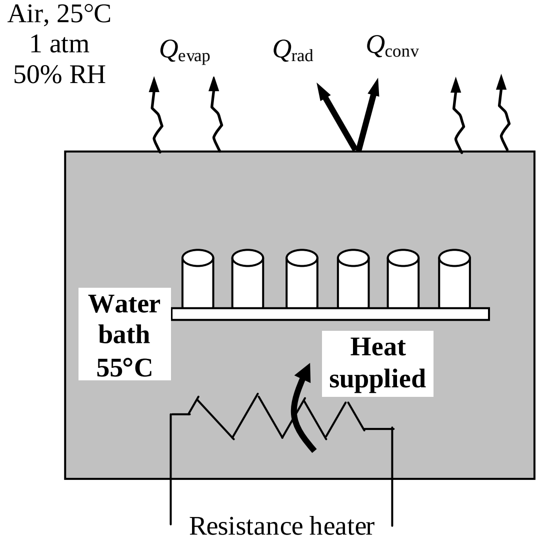
Noting that the atmospheric pressure is 1 atm = 14.7 psia, substituting the known quantities gives

$$T_s = 80°\text{F} - \frac{1060 \text{ Btu/lbm}}{(0.24 \text{ Btu/lbm.°F})(0.856)^{2/3}}\left(\frac{18 \text{ lbm/lbmol}}{29 \text{ lbm/lbmol}}\right)\frac{(0.2563 - 0.152)\text{ psia}}{14.7 \text{ psia}} = \mathbf{58.4^o\ F}$$

Therefore, the temperature of the drink can be lowered to 58.4°F by this process.

Discussion Note that the value obtained is very close to the assumed value of 60°F for the surface temperature. Therefore, there is no need to repeat the calculations with properties at the new surface temperature of 58.7°F

14-117 Glass bottles are washed in hot water in an uncovered rectangular glass washing bath. The rates of heat loss from the top and side surfaces of the bath by radiation, natural convection, and evaporation as well as the rates of heat and water mass that need to be supplied to the water are to be determined.



Assumptions **1** The low mass flux conditions exist so that the Chilton-Colburn analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 300 K). **2** Both air and water vapor at specified conditions are ideal gases (the error involved in this assumption is less than 1 percent). **3** The entire water body and the metal container are maintained at a uniform temperature of 55°C. **4** Heat losses from the bottom surface are negligible. **5** The air motion around the bath is negligible so that there are no forced convection effects.

Properties The air-water vapor mixture is assumed to be dilute, and thus we can use dry air properties for the mixture at the average temperature of $(T_\infty + T_s)/2 =$ (25+55)/2 = 40°C = 313 K. The properties of dry air at 40°C and 1 atm are, from Table A-15,

$$k = 0.0266\ \text{W/m}\cdot°\text{C}, \qquad \text{Pr} = 0.726$$

$$\alpha = 2.35\times10^{-5}\ \text{m}^2/\text{s} \qquad \nu = 1.70\times10^{-5}\ \text{m}^2/\text{s}$$

The mass diffusivity of water vapor in air at the average temperature of 313 K is determined from Eq. 14-15 to be

$$D_{AB} = D_{\text{H}_2\text{O-air}} = 1.87\times10^{-10}\frac{T^{2.072}}{P} = 1.87\times10^{-10}\frac{(313\text{K})^{2.072}}{1\text{atm}} = 2.77\times10^{-5}\ \text{m}^2/\text{s}$$

The saturation pressure of water at 25°C is $P_{\text{sat@25°C}} = 3.169$ kPa. Properties of water at 55°C are $h_{fg} = 2371$ kJ/kg and $P_v = 15.76$ kPa (Table A-9). The specific heat of water at the average temperature of (15+55)/2 = 35°C is C_p = 4.178 kJ/kg.°C.

The gas constants of dry air and water are R_{air} = 0.287 kPa.m^3/kg.K and R_{water} = 0.4615 kPa.m^3/kg.K (Table A-1). Also, the emissivities of water and the sheet metal are given to be 0.61 and 0.95, respectively, and the specific heat of glass is given to be 1.0 kJ/kg.°C.

Analysis (*a*) The mass flow rate of glass bottles through the water bath in steady operation is

$$\dot{m}_{\text{bottle}} = m_{\text{bottle}} \times \text{Bottle flow rate} = (0.150\ \text{kg/bottle})(800\ \text{bottles/min}) = 120\ \text{kg/min} = 2\ \text{kg/s}$$

Then the rate of heat removal by the bottles as they are heated from 25 to 55°C is

$$\dot{Q}_{\text{bottle}} = \dot{m}_{\text{bottle}} C_p \Delta T = (2\,\text{kg/s})(1\text{kJ/kg.°C})(55-25)°\text{C} = 60{,}000\,\text{W}$$

The amount of water removed by the bottles is

$$\dot{m}_{\text{water,out}} = (\text{Flow rate of bottles})(\text{Water removed per bottle})$$
$$= (800\,\text{bottles/min})(0.6\text{g/bottle}) = 480\text{g/min} = 8\times10^{-3}\ \text{kg/s}$$

Noting that the water removed by the bottles is made up by fresh water entering at 15°C, the rate of heat removal by the water that sticks to the bottles is

$$\dot{Q}_{\text{water removed}} = \dot{m}_{\text{water removed}} C_p \Delta T = (8\times10^{-3}\ \text{kg/s})(4178\,\text{J/kg·°C})(55-15)°\text{C} = 1337\ \text{W}$$

Therefore, the total amount of heat removed by the wet bottles is

$$\dot{Q}_{\text{total, removed}} = \dot{Q}_{\text{glass removed}} + \dot{Q}_{\text{water removed}} = 60{,}000 + 1337 = \mathbf{61{,}337\ W}$$

(*b*) The rate of heat loss from the top surface of the water bath is the sum of the heat losses by radiation, natural convection, and evaporation. Then the radiation heat loss from the top surface of water to the surrounding surfaces is

$$\dot{Q}_{\text{rad,top}} = \varepsilon A\sigma(T_s^4 - T_{\text{surr}}^4) = (0.95)(8\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[(55+273\text{ K})^4 - (15+273\text{ K})^4] = 2023\text{ W}$$

The air at the water surface is saturated, and thus the vapor pressure at the surface is simply the saturation pressure of water at the surface temperature (15.76 kPa at 55°C). The vapor pressure of air far from the water surface is determined from

$$P_{v,\infty} = \phi P_{\text{sat@}T_\infty} = (0.50)P_{\text{sat@25°C}} = (0.50)(3.169\text{ kPa}) = 1.585\text{ kPa}$$

Treating the water vapor and the air as ideal gases and noting that the total atmospheric pressure is the sum of the vapor and dry air pressures, the densities of the water vapor, dry air, and their mixture at the water-air interface and far from the surface are determined to be

At the surface:

$$\rho_{v,s} = \frac{P_{v,s}}{R_v T_s} = \frac{15.76\text{ kPa}}{(0.4615\text{ kPa.m}^3/\text{kg}\cdot\text{K})(55+273\text{ K})} = 0.1041\text{ kg/m}^3$$

$$\rho_{a,s} = \frac{P_{a,s}}{R_a T_s} = \frac{(101.325-15.76)\text{ kPa}}{(0.287\text{ kPa.m}^3/\text{kg}\cdot\text{K})(55+273\text{ K})} = 0.9090\text{ kg/m}^3$$

$$\rho_s = \rho_{v,s} + \rho_{a,s} = 0.1041 + 0.9090 = 1.0131\text{ kg/m}^3$$

and

Away from the surface:

$$\rho_{v,\infty} = \frac{P_{v,\infty}}{R_v T_\infty} = \frac{1.585\text{ kPa}}{(0.4615\text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(25+273\text{ K})} = 0.0115\text{ kg/m}^3$$

$$\rho_{a,\infty} = \frac{P_{a,\infty}}{R_a T_\infty} = \frac{(101.325-1.585)\text{ kPa}}{(0.287\text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(25+273\text{ K})} = 1.1662\text{ kg/m}^3$$

$$\rho_\infty = \rho_{v,\infty} + \rho_{a,\infty} = 0.0115 + 1.1662 = 1.1777\text{ kg/m}^3$$

Note that $\rho_\infty > \rho_s$, and thus this corresponds to hot surface facing up. The area of the top surface of the water bath is A_s = 2 m × 4 m = 8 m^2 and its perimeter is p = 2(2 + 4) = 12 m. Therefore, the characteristic length is

$$L = \frac{A_s}{p} = \frac{8\text{ m}^2}{12\text{ m}} = 0.667\text{ m}$$

Then using densities (instead of temperatures) since the mixture is not homogeneous, the Grashoff number is determined to be

$$\text{Gr} = \frac{g(\rho_\infty - \rho_s)L^3}{\rho_{\text{ave}}\nu^2} = \frac{(9.81\text{ m/s}^2)(1.1777-1.0131\text{ kg/m}^3)(0.667\text{ m})^3}{[(1.1777+1.0131)/2\text{ kg/m}^3](1.70\times10^{-5}\text{ m}^2/\text{s})^2} = 1.51\times10^9$$

Recognizing that this is a natural convection problem with hot horizontal surface facing up, the Nusselt number and the convection heat transfer coefficients are determined to be

$$\text{Nu} = 0.15(\text{Gr Pr})^{1/3} = 0.15(1.51\times10^9\times0.726)^{1/3} = 155$$

and $$h_{\text{conv}} = \frac{\text{Nu}k}{L} = \frac{(155)(0.0266\text{ W/m}\cdot°\text{C})}{0.667\text{ m}} = 6.17\text{ W/m}^2\cdot°\text{C}$$

Then the natural convection heat transfer rate becomes

$$\dot{Q}_{\text{conv}} = h_{\text{conv}}A_s(T_s - T_\infty) = (6.17\text{ W/m}^2\cdot°\text{C})(8\text{ m}^2)(55-25)°\text{C} = \mathbf{1480\text{ W}}$$

(*c*) Utilizing the analogy between heat and mass convection, the mass transfer coefficient is determined the same way by replacing Pr by Sc. The Schmidt number is determined from its definition to be

$$\text{Sc} = \frac{\nu}{D_{AB}} = \frac{1.70\times10^{-5}\text{ m}^2/\text{s}}{2.77\times10^{-5}\text{ m}^2/\text{s}} = 0.614$$

The Sherwood number and the mass transfer coefficients are determined to be

$$\text{Sh} = 0.15(\text{GrSc})^{1/3} = 0.15(1.51\times10^9\times0.614)^{1/3} = 146$$

$$h_{\text{mass}} = \frac{\text{Sh}D_{AB}}{L} = \frac{(146)(2.77\times10^{-5}\ \text{m}^2/\text{s})}{0.667\ \text{m}} = 0.00606\ \text{m/s}$$

Then the evaporation rate and the rate of heat transfer by evaporation become

$$\begin{aligned}\dot{m}_v &= h_{\text{mass}} A_s(\rho_{v,s} - \rho_{v,\infty})\\ &= (0.00606\ \text{m/s})(8\ \text{m}^2)(0.1041 - 0.0116)\text{kg/m}^3\\ &= 0.00448\ \text{kg/s} = 16.1\ \text{kg/h}\end{aligned}$$

and $\dot{Q}_{\text{evap}} = \dot{m}_v h_{fg} = (0.00448\ \text{kg/s})(2371\ \text{kJ/kg}) = 10.6\ \text{kW} = 10{,}600\ \text{W}$

Then the total rate of heat loss from the open top surface of the bath to the surrounding air and surfaces is

$$\dot{Q}_{\text{total, top}} = \dot{Q}_{\text{rad}} + \dot{Q}_{\text{conv}} + \dot{Q}_{\text{evap}} = 2023 + 1480 + 10{,}600 = \mathbf{14{,}103\ W}$$

Therefore, if the water bath is heated electrically, a 14 kW resistance heater will be needed just to make up for the heat loss from the top surface.

(*c*) The side surfaces are vertical plates, and treating the air as dry air for simplicity, heat transfer from them by natural convection is determined to be

$$\text{Gr} = \frac{g\beta(T_s - T_\infty)L^3}{\nu^2} = \frac{(9.81\ \text{m/s}^2)(1/313\ \text{K})(55-25)\ \text{K})(1\ \text{m})^3}{(1.70\times10^{-5}\ \text{m}^2/\text{s})^2} = 3.25\times10^9$$

$$\text{Nu} = 0.1(\text{Gr Pr})^{1/3} = 0.1(3.25\times10^9\times0.726)^{1/3} = 133$$

$$h_{\text{conv}} = \frac{\text{Nu}k}{L} = \frac{(133)(0.0266\ \text{W/m}\cdot{}^\circ\text{C})}{1\ \text{m}} = 3.54\ \text{W/m}^2\cdot{}^\circ\text{C}$$

$$\dot{Q}_{\text{conv, side}} = h_{\text{conv}} A_s(T_s - T_\infty) = (3.54\ \text{W/m}^2\cdot{}^\circ\text{C})(12\times1\ \text{m}^2)(55-25)^\circ\text{C} = 1275\ \text{W}$$

The radiation heat loss from the side surfaces of the bath to the surrounding surfaces is

$$\dot{Q}_{\text{rad,side}} = \varepsilon A_s\sigma(T_s^4 - T_{\text{surr}}^4) = (0.61)(12\ \text{m}\times1\ \text{m})(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(55+273\ \text{K})^4 - (15+273\ \text{K})^4] = 2498\ \text{W}$$

and $\dot{Q}_{\text{total, side}} = \dot{Q}_{\text{conv}} + \dot{Q}_{\text{rad}} = 1275 + 2498 = \mathbf{3773\ W}$

(*d*) The rate at which water must be supplied to the maintain steady operation is equal to the rate of water removed by the bottles plus the rate evaporation,

$$\dot{m}_{\text{make-up}} = \dot{m}_{\text{removed}} + \dot{m}_{\text{evap}} = 0.00800 + 0.00448 = \mathbf{0.01248\ kg/s = 44.9\ kg/h}$$

Noting that the entire make-up water enters the bath 15°C, the rate of heat supply to preheat the make-up water to 55°C is

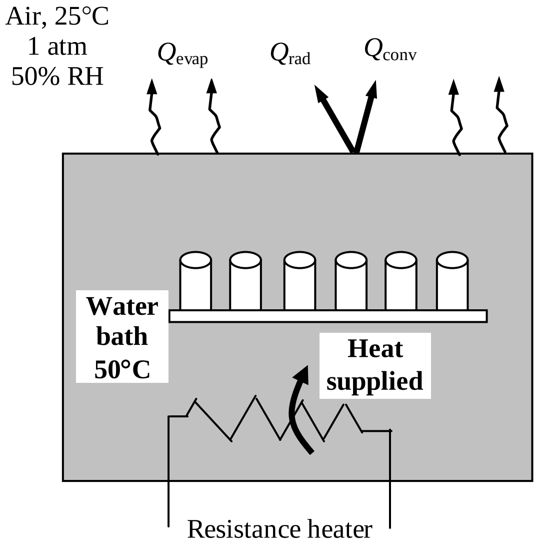
$$\dot{Q}_{\text{preheating water}} = \dot{m}_{\text{make-up water}} C_p\,\Delta T = (0.01248\ \text{kg/s})(4178\ \text{J/kg.}^\text{o}\text{C})(55-15)^\text{o}\text{C} = 2086\ \text{W}$$

Then the rate of required heat supply for the bath becomes the sum of heat losses from the top and side surfaces, plus the heat needed for preheating the make-up water and the bottles,

$$\begin{aligned}\dot{Q}_{\text{total}} &= \dot{Q}_{\text{bottle}} + \left(\dot{Q}_{\text{rad}} + \dot{Q}_{\text{conv}} + \dot{Q}_{\text{evap}}\right)_{\text{top}} + \left(\dot{Q}_{\text{rad}} + \dot{Q}_{\text{conv}}\right)_{\text{side}} + \dot{Q}_{\text{makeup water}}\\ &= 60{,}000 + 14{,}103 + 3773 + 2086 = \mathbf{79{,}962\ W}\end{aligned}$$

Therefore, the heater must be able to supply heat at a rate of 80 kW to maintain steady operating conditions

14-118 Glass bottles are washed in hot water in an uncovered rectangular glass washing bath. The rates of heat loss from the top and side surfaces of the bath by radiation, natural convection, and evaporation as well as the rates of heat and water mass that need to be supplied to the water are to be determined.



Assumptions **1** The low mass flux conditions exist so that the Chilton-Colburn analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 300 K). **2** Both air and water vapor at specified conditions are ideal gases (the error involved in this assumption is less than 1 percent). **3** The entire water body and the metal container are maintained at a uniform temperature of 50°C. **4** Heat losses from the bottom surface are negligible. **5** The air motion around the bath is negligible so that there are no forced convection effects.

Properties The air-water vapor mixture is assumed to be dilute, and thus we can use dry air properties for the mixture at the average temperature of $(T_\infty + T_s)/2 =$ (25+50)/2 = 37.5°C = 310.5 K. The properties of dry air at 310.5 K and 1 atm are, from Table A-15,

$$k = 0.0264\ \text{W/m}\cdot{}^\circ\text{C}, \quad \Pr = 0.726$$

$$\alpha = 2.31\times10^{-5}\ \text{m}^2/\text{s} \quad \nu = 1.68\times10^{-5}\ \text{m}^2/\text{s}$$

The mass diffusivity of water vapor in air at the average temperature of 310.5 K is, from Eq. 14-15,

$$D_{AB} = D_{\text{H}_2\text{O-air}} = 1.87\times10^{-10}\frac{T^{2.072}}{P} = 1.87\times10^{-10}\frac{(310.5\text{K})^{2.072}}{1\text{atm}} = 2.72\times10^{-5}\ \text{m}^2/\text{s}$$

The saturation pressure of water at 25°C is $P_{\text{sat@25°C}} = 3.169$ kPa. Properties of water at 50°C are $h_{fg} = 2383$ kJ/kg and $P_v = 12.35$ kPa (Table A-9). The specific heat of water at the average temperature of (15+50)/2 = 32.5°C is C_p = 4.178 kJ/kg.°C.

The gas constants of dry air and water are R_{air} = 0.287 kPa.m^3/kg.K and R_{water} = 0.4615 kPa.m^3/kg.K (Table A-1). Also, the emissivities of water and the sheet metal are given to be 0.61 and 0.95, respectively, and the specific heat of glass is given to be 1.0 kJ/kg.°C.

Analysis (*a*) The mass flow rate of glass bottles through the water bath in steady operation is

$$\dot{m}_{\text{bottle}} = m_{\text{bottle}} \times \text{Bottle flow rate} = (0.150\ \text{kg/bottle})(800\ \text{bottles/min}) = 120\ \text{kg/min} = 2\ \text{kg/s}$$

Then the rate of heat removal by the bottles as they are heated from 25 to 55°C is

$$\dot{Q}_{\text{bottle}} = \dot{m}_{\text{bottle}} C_p \Delta T = (2\ \text{kg/s})(1\text{kJ/kg.}^\circ\text{C})(55-25)^\circ\text{C} = 60{,}000\ \text{W}$$

The amount of water removed by the bottles is

$$\dot{m}_{\text{water,out}} = (\text{Flow rate of bottles})(\text{Water removed per bottle})$$
$$= (800\ \text{bottles/min})(0.6\text{g/bottle}) = 480\text{g/min} = 8\times10^{-3}\ \text{kg/s}$$

Noting that the water removed by the bottles is made up by fresh water entering at 15°C, the rate of heat removal by the water that sticks to the bottles is

$$\dot{Q}_{\text{water removed}} = \dot{m}_{\text{water removed}} C_p \Delta T = (8\times10^{-3}\ \text{kg/s})(4178\ \text{J/kg}\cdot{}^\circ\text{C})(55-15)^\circ\text{C} = 1337\ \text{W}$$

Therefore, the total amount of heat removed by the wet bottles is

$$\dot{Q}_{\text{total, removed}} = \dot{Q}_{\text{glass removed}} + \dot{Q}_{\text{water removed}} = 60{,}000 + 1337 = \mathbf{61{,}337\ W}$$

(*b*) The rate of heat loss from the top surface of the water bath is the sum of the heat losses by radiation, natural convection, and evaporation. Then the radiation heat loss from the top surface of water to the surrounding surfaces is

$$\dot{Q}_{\text{rad,top}} = \varepsilon A_s \sigma (T_s^4 - T_{\text{surr}}^4) = (0.95)(8\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(50+273\ \text{K})^4 - (15+273\ \text{K})^4] = 1726\ \text{W}$$

The air at the water surface is saturated, and thus the vapor pressure at the surface is simply the saturation pressure of water at the surface temperature (12.35 kPa at 50°C). The vapor pressure of air far from the water surface is determined from

$$P_{v,\infty} = \phi P_{\text{sat@}T_\infty} = (0.50)P_{\text{sat@25°C}} = (0.50)(3.169\text{ kPa}) = 1.585\text{ kPa}$$

Treating the water vapor and the air as ideal gases and noting that the total atmospheric pressure is the sum of the vapor and dry air pressures, the densities of the water vapor, dry air, and their mixture at the water-air interface and far from the surface are determined to be

At the surface:

$$\rho_{v,s} = \frac{P_{v,s}}{R_v T_s} = \frac{12.35\text{ kPa}}{(0.4615\text{ kPa.m}^3/\text{kg}\cdot\text{K})(50+273\text{ K})} = 0.0829\text{ kg/m}^3$$

$$\rho_{a,s} = \frac{P_{a,s}}{R_a T_s} = \frac{(101.325-12.35)\text{ kPa}}{(0.287\text{ kPa.m}^3/\text{kg}\cdot\text{K})(50+273\text{ K})} = 0.9598\text{ kg/m}^3$$

$$\rho_s = \rho_{v,s} + \rho_{a,s} = 0.0829 + 0.9598 = 1.0427\text{ kg/m}^3$$

and

Away from the surface:

$$\rho_{v,\infty} = \frac{P_{v,\infty}}{R_v T_\infty} = \frac{1.585\text{ kPa}}{(0.4615\text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(25+273\text{ K})} = 0.0115\text{ kg/m}^3$$

$$\rho_{a,\infty} = \frac{P_{a,\infty}}{R_a T_\infty} = \frac{(101.325-1.585)\text{ kPa}}{(0.287\text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(25+273\text{ K})} = 1.1662\text{ kg/m}^3$$

$$\rho_\infty = \rho_{v,\infty} + \rho_{a,\infty} = 0.0115 + 1.1662 = 1.1777\text{ kg/m}^3$$

Note that $\rho_\infty > \rho_s$, and thus this corresponds to hot surface facing up. The area of the top surface of the water bath is A_s = 2 m × 4 m = 8 m^2 and its perimeter is p = 2(2 + 4) = 12 m. Therefore, the characteristic length is

$$L = \frac{A_s}{p} = \frac{8\text{ m}^2}{12\text{ m}} = 0.667\text{ m}$$

Then using densities (instead of temperatures) since the mixture is not homogeneous, the Grashoff number is determined to be

$$\text{Gr} = \frac{g(\rho_\infty - \rho_s)L^3}{\rho_{\text{ave}}\nu^2} = \frac{(9.81\text{ m/s}^2)(1.1777-1.0427\text{ kg/m}^3)(0.667\text{ m})^3}{[(1.1777+1.0427)/2\text{ kg/m}^3](1.68\times10^{-5}\text{ m}^2/\text{s})^2} = 1.27\times10^9$$

Recognizing that this is a natural convection problem with hot horizontal surface facing up, the Nusselt number and the convection heat transfer coefficients are determined to be

$$\text{Nu} = 0.15(\text{Gr Pr})^{1/3} = 0.15(1.27\times10^9\times0.726)^{1/3} = 146$$

and $$h_{\text{conv}} = \frac{\text{Nu}k}{L} = \frac{(146)(0.0264\text{ W/m}\cdot°\text{C})}{0.667\text{ m}} = 5.78\text{ W/m}^2\cdot°\text{C}$$

Then the natural convection heat transfer rate becomes

$$\dot{Q}_{\text{conv}} = h_{\text{conv}}A_s(T_s - T_\infty) = (5.78\text{ W/m}^2\cdot°\text{C})(8\text{ m}^2)(50-25)°\text{C} = 1156\text{ W}$$

(*c*) Utilizing the analogy between heat and mass convection, the mass transfer coefficient is determined the same way by replacing Pr by Sc. The Schmidt number is determined from its definition to be

$$\text{Sc} = \frac{\nu}{D_{AB}} = \frac{1.68\times10^{-5}\text{ m}^2/\text{s}}{2.72\times10^{-5}\text{ m}^2/\text{s}} = 0.618$$

The Sherwood number and the mass transfer coefficients are determined to be

$$\text{Sh} = 0.15(\text{GrSc})^{1/3} = 0.15(1.27\times10^9\times0.618)^{1/3} = 138$$

$$h_{\text{mass}} = \frac{\text{Sh}D_{AB}}{L} = \frac{(138)(2.72\times10^{-5}\text{ m}^2/\text{s})}{0.667\text{ m}} = 0.00564\text{ m/s}$$

Then the evaporation rate and the rate of heat transfer by evaporation become

$$\begin{aligned}\dot{m}_v &= h_{\text{mass}} A_s(\rho_{v,s} - \rho_{v,\infty})\\ &= (0.00567\text{ m/s})(8\text{ m}^2)(0.0829 - 0.0116)\text{kg/m}^3\\ &= 0.00323\text{ kg/s} = 11.6\text{ kg/h}\end{aligned}$$

and $\dot{Q}_{\text{evap}} = \dot{m}_v h_{fg} = (0.00323\text{ kg / s})(2383\text{ kJ / kg}) = 7.67\text{ kW} = 7670\text{ W}$

The total rate of heat loss from the open top surface of the bath to the surrounding air and surfaces is

$$\dot{Q}_{\text{total, top}} = \dot{Q}_{\text{rad}} + \dot{Q}_{\text{conv}} + \dot{Q}_{\text{evap}} = 1726 + 1156 + 7670 = \mathbf{10{,}552\ W}$$

Therefore, if the water bath is heated electrically, a 10.55 kW resistance heater will be needed just to make up for the heat loss from the top surface.

(*c*) The side surfaces are vertical plates, and treating the air as dry air for simplicity, heat transfer from them by natural convection is determined to be

$$\text{Gr} = \frac{g\beta(T_s - T_\infty)L^3}{\nu^2} = \frac{(9.81\text{ m/s}^2)(1/310.5\text{ K})(50 - 25)\text{ K})(1\text{ m})^3}{(1.68\times10^{-5}\text{ m}^2/\text{s})^2} = 2.83\times10^9$$

$$\text{Nu} = 0.1(\text{Gr Pr})^{1/3} = 0.1(2.83\times10^9\times0.726)^{1/3} = 127$$

$$h_{\text{conv}} = \frac{\text{Nu}k}{L} = \frac{(127)(0.0264\text{ W/m}\cdot{}^\circ\text{C})}{1\text{ m}} = 3.36\text{ W/m}^2\cdot{}^\circ\text{C}$$

$$\dot{Q}_{\text{conv, side}} = h_{\text{conv}} A_s(T_s - T_\infty) = (3.36\text{ W/m}^2\cdot{}^\circ\text{C})(12\times1\text{ m}^2)(50 - 25)^\circ\text{C} = 1007\text{ W}$$

The radiation heat loss from the side surfaces of the bath to the surrounding surfaces is

$\dot{Q}_{\text{rad,side}} = \varepsilon A_s\sigma(T_s^4 - T_{\text{surr}}^4) = (0.61)(12\text{ m}\times1\text{ m})(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)[(50 + 273\text{ K})^4 - (15 + 273\text{ K})^4] = 1662\text{ W}$ and $\dot{Q}_{\text{total, side}} = \dot{Q}_{\text{conv}} + \dot{Q}_{\text{rad}} = 1007 + 1662 = \mathbf{2669\ W}$

(*d*) The rate at which water must be supplied to the maintain steady operation is equal to the rate of water removed by the bottles plus the rate evaporation,

$$\dot{m}_{\text{make-up}} = \dot{m}_{\text{removed}} + \dot{m}_{\text{evap}} = 0.00800 + 0.00323 = \mathbf{0.01123\ kg / s = 40.4\ kg / h}$$

Noting that the entire make-up water enters the bath 15°C, the rate of heat supply to preheat the make-up water to 50°C is

$$\dot{Q}_{\text{preheating water}} = \dot{m}_{\text{make-up water}} C_p\,\Delta T = (0.01123\text{ kg / s})(4178\text{ J / kg}\cdot{}^\circ\text{C})(50 - 15)^\circ\text{C} = 1642\text{ W}$$

Then the rate of required heat supply for the bath becomes the sum of heat losses from the top and side surfaces, plus the heat needed for preheating the make-up water and the bottles,

$$\begin{aligned}\dot{Q}_{\text{total}} &= \dot{Q}_{\text{bottle}} + \left(\dot{Q}_{\text{rad}} + \dot{Q}_{\text{conv}} + \dot{Q}_{\text{evap}}\right)_{\text{top}} + \left(\dot{Q}_{\text{rad}} + \dot{Q}_{\text{conv}}\right)_{\text{side}} + \dot{Q}_{\text{makeup water}}\\ &= 60{,}000 + 10{,}552 + 2669 + 1642 = \mathbf{74{,}863\ W}\end{aligned}$$

Therefore, the heater must be able to supply heat at a rate of 75 kW to maintain steady operating conditions

14-119 A person is standing outdoors in windy weather. The rates of heat loss from the head by radiation, forced convection, and evaporation are to be determined for the cases of the head being wet and dry.

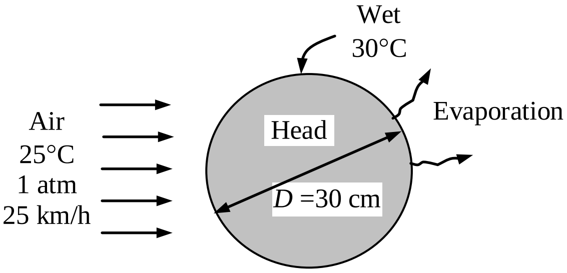
Assumptions **1** The low mass flux conditions exist so that the Chilton-Colburn analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 300 K). **2** Both air and water vapor at specified conditions are ideal gases (the error involved in this assumption is less than 1 percent). **3** The head can be approximated as a sphere of 30 cm diameter maintained at a uniform temperature of 30°C. **4** The surrounding surfaces are at the same temperature as the ambient air.

Properties The air-water vapor mixture is assumed to be dilute, and thus we can use dry air properties for the mixture. The properties of air at the free stream temperature of 25°C and 1 atm are, from Table A-15,

$k = 0.0255\,\text{W/m}\cdot\text{C}, \quad \text{Pr} = 0.73$

$\mu = 1.85\times10^{-5}\ \text{kg/m}\cdot\text{s} \quad \nu = 1.56\times10^{-5}\ \text{m}^2/\text{s}$

Also, $\mu_s = \mu_{@30°\text{C}} = 1.87\times10^{-5}\ \text{kg/m}\cdot\text{s}$. The mass diffusivity of water vapor in air at the average temperature of (25 + 30)/2 = 27.5°C = 300.5 K is, from Eq. 14-15,



$$D_{AB} = D_{\text{H}_2\text{O-air}} = 1.87\times10^{-10}\frac{T^{2.072}}{P} = 1.87\times10^{-10}\frac{(300.5\text{K})^{2.072}}{1\text{atm}} = 2.55\times10^{-5}\ \text{m}^2/\text{s}$$

The saturation pressure of water at 25°C is $P_{\text{sat@25°C}} = 3.169$ kPa. Properties of water at 30°C are $h_{fg} = 2431$ kJ / kg and $P_v = 4.246$ kPa (Table A-9).

The gas constants of dry air and water are R_{air} = 0.287 kPa.m^3/kg.K and R_{water} = 0.4615 kPa.m^3/kg.K (Table A-1). Also, the emissivity of the head is given to be 0.95.

Analysis (*a*) When the head is dry, heat transfer from the head is by forced convection and radiation only. The radiation heat transfer is

$$\dot{Q}_{\text{rad}} = \varepsilon A_s\sigma(T_s^4 - T_{\text{surr}}^4) = (0.95)[\pi(0.3\,\text{m})^2](5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(30+273\,\text{K})^4-(25+273\,\text{K})^4] = 8.3\,\text{W}$$

The Reynolds number for flow over the head is

$$\text{Re} = \frac{\text{V}_\infty D}{\nu} = \frac{(25/3.6\text{m/s})(0.3\text{m})}{1.56\times10^{-5}\,\text{m}^2/\text{s}} = 133{,}550$$

Then the Nusselt number and the heat transfer coefficient become

$$\text{Nu} = 2 + \left[0.4\,\text{Re}^{1/2} + 0.06\,\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2 + \left[0.4(133{,}550)^{1/2} + 0.06(133{,}550)^{2/3}\right](0.73)^{0.4}\left(\frac{1.85\times10^{-5}}{1.87\times10^{-5}}\right)^{1/4} = 269$$

$$h = \frac{k}{D}Nu = \frac{0.0255\,\text{W/m}\cdot°\text{C}}{0.3\text{m}}(269) = 22.9\,\text{W/m}^2\cdot°\text{C}$$

Then the rate of convection heat transfer from the head becomes

$$\dot{Q}_{\text{conv}} = hA_s(T_s - T_\infty) = (22.9\,\text{W/m}^2.°\text{C})[\pi(0.3\text{m})^2](30-25)°\text{C} = 32.3\text{W}$$

Therefore,

$$\dot{Q}_{\text{total,dry}} = \dot{Q}_{\text{conv}} + \dot{Q}_{\text{rad}} = 32.3 + 8.3 = \mathbf{40.6\,W}$$

(*b*) When the head is wet, there is additional heat transfer mechanism by evaporation. The Schmidt number is

$$\text{Sc} = \frac{\nu}{D_{AB}} = \frac{1.56\times10^{-5}\ \text{m}^2/\text{s}}{2.55\times10^{-5}\ \text{m}^2/\text{s}} = 0.612$$

The Sherwood number and the mass transfer coefficients are determined to be

$$\text{Sh} = 2 + \left[0.4\,\text{Re}^{1/2} + 0.06\,\text{Re}^{2/3}\right]\text{Sc}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2 + \left[0.4(133{,}550)^{1/2} + 0.06(133{,}550)^{2/3}\right](0.612)^{0.4}\left(\frac{1.85\times10^{-5}}{1.87\times10^{-5}}\right)^{1/4} = 251$$

$$h_{\text{mass}} = \frac{\text{Sh}D_{AB}}{L} = \frac{(251)(2.55\times10^{-5}\ \text{m}^2/\text{s})}{0.3\,\text{m}} = 0.0213\,\text{m/s}$$

The air at the water surface is saturated, and thus the vapor pressure at the surface is simply the saturation pressure of water at the surface temperature (4.246 kPa at 30°C). The vapor pressure of air far from the water surface is determined from

$$P_{v,\infty} = \phi P_{\text{sat@}T_\infty} = (0.40)\,P_{\text{sat@25°C}} = (0.40)(3.169\ \text{kPa}) = 1.268\ \text{kPa}$$

Treating the water vapor and the air as ideal gases, the vapor densities at the water-air interface and far from the surface are determined to be

At the surface: $$\rho_{v,s} = \frac{P_{v,s}}{R_v T_s} = \frac{4.246\ \text{kPa}}{(0.4615\ \text{kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(30+273)\ \text{K}} = 0.0304\ \text{kg/m}^3$$

Away from the surface: $$\rho_{v,s} = \frac{P_{v,s}}{R_v T_s} = \frac{1.268\ \text{kPa}}{(0.4615\ \text{kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(25+273)\ \text{K}} = 0.0092\ \text{kg/m}^3$$

Then the evaporation rate and the rate of heat transfer by evaporation become

$$\begin{aligned}\dot{m}_v &= h_{\text{mass}}A_s(\rho_{v,s} - \rho_{v,\infty}) = (0.0213\,\text{m/s})[\pi(0.3\,\text{m})^2](0.0304 - 0.0092)\ \text{kg/m}^3 \\ &= 0.000128\ \text{kg/s}\end{aligned}$$

and

$$\dot{Q}_{\text{evap}} = \dot{m}_v h_{fg} = (0.000128\ \text{kg/s})(2431\ \text{kJ/kg}) = 0.311\ \text{kW} = 311\ \text{W}$$

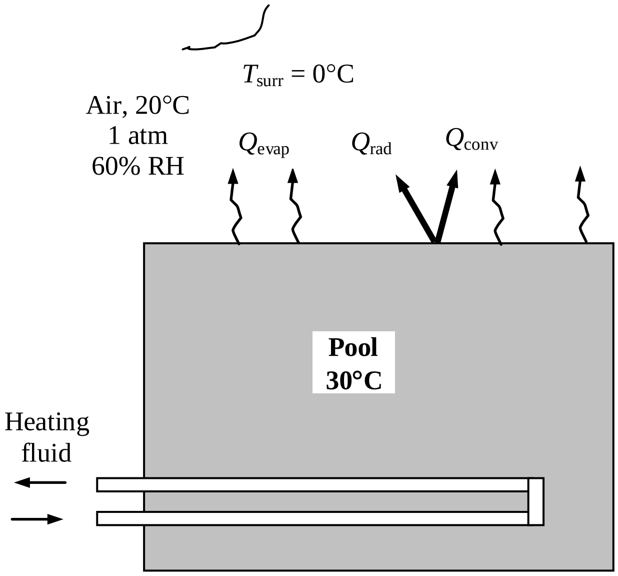
Then the total rate of heat loss from the wet head to the surrounding air and surfaces becomes

$$\dot{Q}_{\text{total,wet}} = \dot{Q}_{\text{conv}} + \dot{Q}_{\text{rad}} + \dot{Q}_{\text{evap}} = 32.3 + 8.3 + 311 = \mathbf{351.6\,W}$$

Discussion Note that the heat loss from the head can be increased by more than 8 times in this case by wetting the head and allowing heat transfer by evaporation.

14-120 The heating system of a heated swimming pool is being designed. The rates of heat loss from the top surface of the pool by radiation, natural convection, and evaporation are to be determined.

Assumptions **1** The low mass flux conditions exist so that the Chilton-Colburn analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 300 K). **2** Both air and water vapor at specified conditions are ideal gases (the error involved in this assumption is less than 1 percent). **3** The entire water body in the pool is maintained at a uniform temperature of 30°C. **4** The air motion around the pool is negligible so that there are no forced convection effects.



Properties The air-water vapor mixture is assumed to be dilute, and thus we can use dry air properties for the mixture at the average temperature of $(T_\infty + T_s)/2$ = (20+30)/2 = 25°C = 298 K. The properties of dry air at 298 K and 1 atm are, from Table A-15,

$$k = 0.0255\ \text{W/m}\cdot{}^\circ\text{C},\ \text{Pr} = 0.73$$

$$\alpha = 2.14\times10^{-5}\ \text{m}^2/\text{s}\quad \nu = 1.56\times10^{-5}\ \text{m}^2/\text{s}$$

The mass diffusivity of water vapor in air at the average temperature of 298 K is determined from Eq. 14-15 to be

$$D_{AB} = D_{\text{H}_2\text{O-air}} = 1.87\times10^{-10}\frac{T^{2.072}}{P}$$

$$= 1.87\times10^{-10}\frac{(298\text{K})^{2.072}}{1\text{atm}} = 2.50\times10^{-5}\ \text{m}^2/\text{s}$$

The saturation pressure of water at 20°C is $P_{\text{sat@20°C}} = 2.339$ kPa. Properties of water at 30°C are $h_{fg} = 2431$ kJ/kg and $P_v = 4.246$ kPa (Table A-9). The gas constants of dry air and water are R_{air} = 0.287 kPa.m^3/kg.K and R_{water} = 0.4615 kPa.m^3/kg.K (Table A-1). The emissivity of water is 0.95 (Table A-15).

Analysis (*a*) Noting that the emissivity of water is 0.95 and the surface area of the pool is $A = (20\text{ m})(20\text{ m}) = 400\text{ m}^2$, heat transfer from the top surface of the pool by radiation is

$$\dot{Q}_{\text{rad}} = \varepsilon A\sigma(T_s^4 - T_{\text{surr}}^4) = (0.95)(400\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)\left[(30+273\text{ K})^4 - (0+273\text{ K})^4\right] = \mathbf{61{,}930\ W}$$

(*b*) The air at the water surface is saturated, and thus the vapor pressure at the surface is simply the saturation pressure of water at the surface temperature (4.246 kPa at 30°C). The vapor pressure of air far from the water surface is determined from

$$P_{v,\infty} = \phi P_{\text{sat@}T_\infty} = (0.60)P_{\text{sat@20°C}} = (0.60)(2.339\text{ kPa}) = 1.40\text{ kPa}$$

Treating the water vapor and the air as ideal gases and noting that the total atmospheric pressure is the sum of the vapor and dry air pressures, the densities of the water vapor, dry air, and their mixture at the water-air interface and far from the surface are determined to be

At the surface:

$$\rho_{v,s} = \frac{P_{v,s}}{R_v T_s} = \frac{4.246\text{ kPa}}{(0.4615\text{ kPa.m}^3/\text{kg}\cdot\text{K})(30+273)\text{ K}} = 0.0304\text{ kg/m}^3$$

$$\rho_{a,s} = \frac{P_{a,s}}{R_a T_s} = \frac{(101.325-4.246)\text{ kPa}}{(0.287\text{ kPa.m}^3/\text{kg}\cdot\text{K})(30+273)\text{ K}} = 1.1164\text{ kg/m}^3$$

$$\rho_s = \rho_{v,s} + \rho_{a,s} = 0.0304 + 1.1164 = 1.1168\text{ kg/m}^3$$

$$\rho_{v,\infty}=\frac{P_{v,\infty}}{R_vT_\infty}=\frac{1.40\ \text{kPa}}{(0.4615\ \text{kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(20+273)\ \text{K}}=0.0104\ \text{kg/m}^3$$

Away from the surface:

$$\rho_{a,\infty}=\frac{P_{a,\infty}}{R_aT_\infty}=\frac{(101.325-1.40)\ \text{kPa}}{(0.287\ \text{kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(20+273)\ \text{K}}=1.1883\ \text{kg/m}^3$$

$$\rho_\infty=\rho_{v,\infty}+\rho_{a,\infty}=0.0104+1.1883=1.1987\ \text{kg/m}^3$$

Note that $\rho_\infty>\rho_s$, and thus this corresponds to hot surface facing up. The perimeter of the top surface of the pool is p = 2(20+ 20) = 80 m. Therefore, the characteristic length is

$$L=\frac{A_s}{p}=\frac{400\ \text{m}^2}{80\ \text{m}}=5\ \text{m}$$

Then using densities (instead of temperatures) since the mixture is not homogeneous, the Grashoff number is determined to be

$$\text{Gr}=\frac{g(\rho_\infty-\rho_s)L^3}{\rho_{\text{ave}}\nu^2}=\frac{(9.81\ \text{m/s}^2)(1.1987-1.1468\ \text{kg/m}^3)(5\ \text{m})^3}{[(1.1968+1.1468)/2\ \text{kg/m}^3](1.56\times10^{-5}\ \text{m}^2/\text{s})^2}=2.26\times10^{11}$$

Recognizing that this is a natural convection problem with hot horizontal surface facing up, the Nusselt number and the convection heat transfer coefficients are determined to be

$$\text{Nu}=0.15(\text{Gr Pr})^{1/3}=0.15(2.26\times10^{11}\times0.73)^{1/3}=823$$

and $$h_{\text{conv}}=\frac{\text{Nu}k}{L}=\frac{(823)(0.0255\ \text{W/m}\cdot{}^\circ\text{C})}{5\ \text{m}}=4.20\ \text{W/m}^2\cdot{}^\circ\text{C}$$

Then natural convection heat transfer rate becomes

$$\dot{Q}_{\text{conv}}=h_{\text{conv}}A_s(T_s-T_\infty)=(4.20\ \text{W/m}^2\cdot{}^\circ\text{C})(400\ \text{m}^2)(30-20)^\circ\text{C}=\mathbf{16{,}780\ W}$$

(*c*) Utilizing the analogy between heat and mass convection, the mass transfer coefficient is determined the same way by replacing Pr by Sc. The Schmidt number is determined from its definition to be

$$\text{Sc}=\frac{\nu}{D_{AB}}=\frac{1.56\times10^{-5}\ \text{m}^2/\text{s}}{2.50\times10^{-5}\ \text{m}^2/\text{s}}=0.624$$

The Sherwood number and the mass transfer coefficients are determined to be

$$\text{Sh}=0.15(\text{GrSc})^{1/3}=0.15(2.26\times10^{11}\times0.624)^{1/3}=781$$

$$h_{\text{mass}}=\frac{\text{Sh}D_{AB}}{L}=\frac{(781)(2.50\times10^{-5}\ \text{m}^2/\text{s})}{5\ \text{m}}=0.00390\ \text{m/s}$$

Then the evaporation rate and the rate of heat transfer by evaporation become

$$\begin{aligned}\dot{m}_v&=h_{\text{mass}}A_s(\rho_{v,s}-\rho_{v,\infty})=(0.00390\ \text{m/s})(400\ \text{m}^2)(0.0304-0.0104)\text{kg/m}^3\\&=0.0312\ \text{kg/s}=112\ \text{kg/h}\end{aligned}$$

and $$\dot{Q}_{\text{evap}}=\dot{m}_vh_{fg}=(0.00312\ \text{kg/s})(2{,}431{,}000\ \text{J/kg})=\mathbf{75{,}850\ W}$$

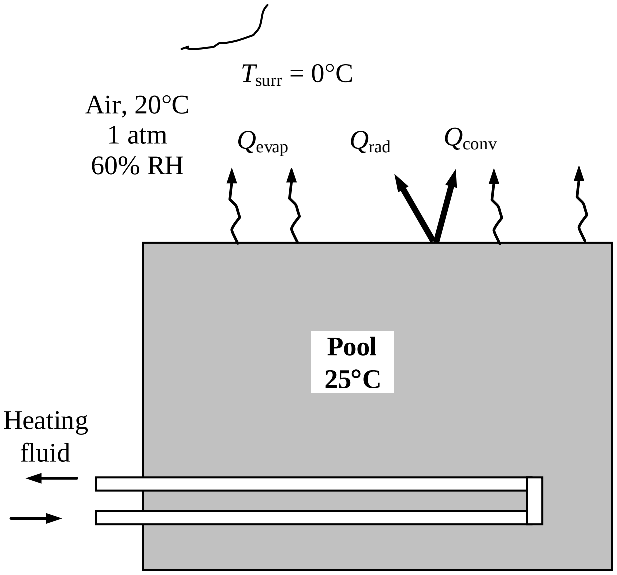
Then the total rate of heat loss from the open top surface of the pool to the surrounding air and surfaces is

$$\dot{Q}_{\text{total, top}}=\dot{Q}_{\text{rad}}+\dot{Q}_{\text{conv}}+\dot{Q}_{\text{evap}}=61{,}930+16{,}780+75{,}850=\mathbf{154{,}560\ W}$$

Therefore, if the pool is heated electrically, a 155 kW resistance heater will be needed to make up for the heat losses from the top surface.

14-121 The heating system of a heated swimming pool is being designed. The rates of heat loss from the top surface of the pool by radiation, natural convection, and evaporation are to be determined.

Assumptions **1** The low mass flux conditions exist so that the Chilton-Colburn analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 300 K). **2** Both air and water vapor at specified conditions are ideal gases (the error involved in this assumption is less than 1 percent). **3** The entire water body in the pool is maintained at a uniform temperature of 25°C. **4** The air motion around the pool is negligible so that there are no forced convection effects.



Properties The air-water vapor mixture is assumed to be dilute, and thus we can use dry air properties for the mixture at the average temperature of $(T_\infty + T_s)/2 =$ (20+25)/2 = 22.5°C = 295.5 K. The properties of dry air at 295.5 K and 1 atm are, from Table A-15,

$$k = 0.0253 \text{W/m}\cdot°\text{C}, \quad \text{Pr} = 0.73$$

$$\alpha = 2.11\times10^{-5}\ \text{m}^2/\text{s} \quad \nu = 1.54\times10^{-5}\ \text{m}^2/\text{s}$$

The mass diffusivity of water vapor in air at the average temperature of 295.5 K is, fromm Eq. 14-15,

$$D_{AB} = D_{\text{H}_2\text{O-air}} = 1.87\times10^{-10}\frac{T^{2.072}}{P}$$

$$= 1.87\times10^{-10}\frac{(295.5\text{K})^{2.072}}{1\text{atm}}$$

$$= 2.46\times10^{-5}\ \text{m}^2/\text{s}$$

The saturation pressure of water at 20°C is $P_{\text{sat@20°C}} = 2.339$ kPa. Properties of water at 25°C are $h_{fg} = 2442$ kJ/kg and $P_v = 3.169$ kPa (Table A-9). The gas constants of dry air and water are $R_{\text{air}} = 0.287$ kPa.m^3/kg.K and $R_{\text{water}} = 0.4615$ kPa.m^3/kg.K (Table A-1). The emissivity of water is 0.95 (Table A-15).

Analysis (*a*) Noting that the emissivity of water is 0.95 and the surface area of the pool is $A_s = (20\text{ m})(20\text{ m}) = 400\text{ m}^2$, heat transfer from the top surface of the pool by radiation is

$$\dot{Q}_{\text{rad}} = \varepsilon A\sigma(T_s^4 - T_{\text{surr}}^4) = (0.95)(400\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)\left[(25+273\text{ K})^4 - (0+273\text{ K})^4\right] = \mathbf{50{,}236\ W}$$

(*b*) The air at the water surface is saturated, and thus the vapor pressure at the surface is simply the saturation pressure of water at the surface temperature (3.169 kPa at 25°C). The vapor pressure of air far from the water surface is determined from

$$P_{v,\infty} = \phi P_{\text{sat@}T_\infty} = (0.60)P_{\text{sat@20°C}} = (0.60)(2.339\text{ kPa}) = 1.40\text{ kPa}$$

Treating the water vapor and the air as ideal gases and noting that the total atmospheric pressure is the sum of the vapor and dry air pressures, the densities of the water vapor, dry air, and their mixture at the water-air interface and far from the surface are determined to be

At the surface:

$$\rho_{v,s} = \frac{P_{v,s}}{R_v T_s} = \frac{3.169\text{ kPa}}{(0.4615\text{ kPa.m}^3/\text{kg}\cdot\text{K})(25+273)\text{ K}} = 0.0230\text{ kg/m}^3$$

$$\rho_{a,s} = \frac{P_{a,s}}{R_a T_s} = \frac{(101.325-3.169)\text{ kPa}}{(0.287\text{ kPa.m}^3/\text{kg}\cdot\text{K})(25+273)\text{ K}} = 1.1477\text{ kg/m}^3$$

$$\rho_s = \rho_{v,s} + \rho_{a,s} = 0.0230 + 1.1477 = 1.1707\text{ kg/m}^3$$

and

$$\rho_{v,\infty} = \frac{P_{v,\infty}}{R_v T_\infty} = \frac{1.40\text{ kPa}}{(0.4615\text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(20+273)\text{ K}} = 0.0104\text{ kg/m}^3$$

Away from the surface:

$$\rho_{a,\infty} = \frac{P_{a,\infty}}{R_a T_\infty} = \frac{(101.325-1.40)\text{ kPa}}{(0.287\text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(20+273)\text{ K}} = 1.1883\text{ kg/m}^3$$

$$\rho_\infty = \rho_{v,\infty} + \rho_{a,\infty} = 0.0104 + 1.1883 = 1.1987\text{ kg/m}^3$$

Note that $\rho_\infty > \rho_s$, and thus this corresponds to hot surface facing up. The perimeter of the top surface of the pool is $p = 2(20+20) = 80$ m. Therefore, the characteristic length is

$$L = \frac{A_s}{p} = \frac{400\text{ m}^2}{80\text{ m}} = 5\text{ m}$$

Then using densities (instead of temperatures) since the mixture is not homogeneous, the Grashoff number is determined to be

$$\text{Gr} = \frac{g(\rho_\infty - \rho_s)L^3}{\rho_{\text{ave}}\nu^2} = \frac{(9.81\text{ m/s}^2)(1.1987-1.1707\text{ kg/m}^3)(5\text{ m})^3}{[(1.1968+1.1707)/2\text{ kg/m}^3](1.54\times10^{-5}\text{ m}^2/\text{s})^2} = 1.24\times10^{11}$$

Recognizing that this is a natural convection problem with hot horizontal surface facing up, the Nusselt number and the convection heat transfer coefficients are determined to be

$$\text{Nu} = 0.15(\text{Gr Pr})^{1/3} = 0.15(1.24\times10^{11}\times0.73)^{1/3} = 674$$

and $$h_{\text{conv}} = \frac{\text{Nu}k}{L} = \frac{(674)(0.0253\text{ W/m}\cdot{}^\circ\text{C})}{5\text{ m}} = 3.41\text{ W/m}^2\cdot{}^\circ\text{C}$$

Then natural convection heat transfer rate becomes

$$\dot{Q}_{\text{conv}} = h_{\text{conv}}A_s(T_s - T_\infty) = (3.41\text{ W/m}^2\cdot{}^\circ\text{C})(400\text{ m}^2)(25-20)^\circ\text{C} = \mathbf{6820\text{ W}}$$

(*c*) Utilizing the analogy between heat and mass convection, the mass transfer coefficient is determined the same way by replacing Pr by Sc. The Schmidt number is determined from its definition to be

$$\text{Sc} = \frac{\nu}{D_{AB}} = \frac{1.54\times10^{-5}\text{ m}^2/\text{s}}{2.45\times10^{-5}\text{ m}^2/\text{s}} = 0.629$$

The Sherwood number and the mass transfer coefficients are determined to be

$$\text{Sh} = 0.15(\text{GrSc})^{1/3} = 0.15(1.24\times10^{11}\times0.629)^{1/3} = 641$$

$$h_{\text{mass}} = \frac{\text{Sh}D_{AB}}{L} = \frac{(641)(2.45\times10^{-5}\text{ m}^2/\text{s})}{5\text{ m}} = 0.00314\text{ m/s}$$

Then the evaporation rate and the rate of heat transfer by evaporation become

$$\begin{aligned}\dot{m}_v &= h_{\text{mass}}A_s(\rho_{v,s} - \rho_{v,\infty}) = (0.00314\text{ m/s})(400\text{ m}^2)(0.0230-0.0104)\text{kg/m}^3\\ &= 0.0158\text{ kg/s} = 57.0\text{ kg/h}\end{aligned}$$

and $$\dot{Q}_{\text{evap}} = \dot{m}_v h_{fg} = (0.0158\text{ kg/s})(2{,}441{,}000\text{ J/kg}) = \mathbf{38{,}570\text{ W}}$$

Then the total rate of heat loss from the open top surface of the pool to the surrounding air and surfaces is

$$\dot{Q}_{\text{total, top}} = \dot{Q}_{\text{rad}} + \dot{Q}_{\text{conv}} + \dot{Q}_{\text{evap}} = 50{,}236 + 6820 + 38{,}570 = \mathbf{95{,}626\text{ W}}$$

Therefore, if the pool is heated electrically, a 96 kW resistance heater will be needed to make up for the heat losses from the top surface.

Review Problems

14-122C (*a*) T, (*b*) F, (*c*) F, (*d*) T

14-123 Henry's law is expressed as

$$y_{\text{i, liquid side}}(0) = \frac{P_{\text{i, gas side}}(0)}{H}$$

Henry's constant H increases with temperature, and thus the fraction of gas i in the liquid $y_{\text{i, liquid side}}$ decreases. Therefore, heating a liquid will drive off the dissolved gases in a liquid.

14-124 The ideal gas relation can be expressed as $PV = NR_uT = mRT$ where R_u is the universal gas constant, whose value is the same for all gases, and R is the gas constant whose value is different for different gases. The molar and mass densities of an ideal gas mixture can be expressed as

$$PV = NR_uT \quad \rightarrow \quad C = \frac{N}{V} = \frac{P}{R_uT} = \text{ constant}$$

and $$PV = mRT \quad \rightarrow \quad \rho = \frac{m}{V} = \frac{P}{RT} \neq \text{ constant}$$

Therefore, for an ideal gas mixture maintained at a constant temperature and pressure, the molar concentration C of the mixture remains constant but this is not necessarily the case for the density ρ of mixture.

14-125E The masses of the constituents of a gas mixture at a specified temperature and pressure are given. The partial pressure of each gas and the volume of the mixture are to be determined.

Assumptions The gas mixture and its constituents are ideal gases.

Properties The molar masses of CO_2 and CH_4 are 44 and 16 kg/kmol, respectively (Table A-1)

Analysis The mole numbers of each gas and of the mixture are

1 lbm CO_2
3 lbm CH_4

600 R
20 psia

CO_2:
$$N_{\mathrm{CO_2}} = \frac{m_{\mathrm{CO_2}}}{M_{\mathrm{CO_2}}} = \frac{1\ \text{lbmol}}{44\ \text{lbmol}} = 0.0227\ \text{lbmol}$$

CH_4:
$$N_{\mathrm{CH_4}} = \frac{m_{\mathrm{CH_4}}}{M_{\mathrm{CH_4}}} = \frac{3\ \text{lbmol}}{16\ \text{lbmol}} = 0.1875\ \text{lbmol}$$

$$N_{\text{total}} = N_{\mathrm{CO_2}} + N_{\mathrm{CH_4}} = 0.0227 + 0.1875 = 0.2102$$

Using the ideal gas relation for the mixture and for the constituents, the volume of the mixture and the partial pressures of the constituents are determined to be

$$V = \frac{NR_uT}{P} = \frac{(0.2102\ \text{lbmol})(10.73\ \text{psia}\cdot\text{ft}^3/\text{lbmol}\cdot\text{R})}{20\ \text{psia}} = \mathbf{67.66\ ft^3}$$

$$P_{\mathrm{CO_2}} = \frac{N_{\mathrm{CO_2}}R_uT}{V} = \frac{(0.0227\ \text{lbmol})(10.73\ \text{psia}\cdot\text{ft}^3/\text{lbmol}\cdot\text{R})(600\ \text{R})}{67.66\ \text{ft}^3} = \mathbf{2.16\ psia}$$

$$P_{\mathrm{CH_4}} = \frac{N_{\mathrm{CH_4}}R_uT}{V} = \frac{(0.1875\ \text{lbmol})(10.73\ \text{psia}\cdot\text{ft}^3/\text{lbmol}\cdot\text{R})(600\ \text{R})}{67.66\ \text{ft}^3} = \mathbf{17.84\ psia}$$

Discussion Note that each constituent of a gas mixture occupies the same volume (the volume of the container), and that the total pressure of a gas mixture is equal to the sum of the partial pressures of its constituents. That is, $P_{\text{total}} = P_{\mathrm{CO_2}} + P_{\mathrm{CH_4}} = 2.16 + 17.84 = 20$ psia.

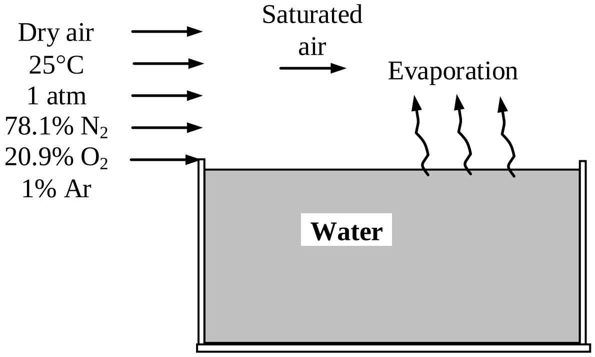
14-126 Dry air flows over a water body at constant pressure and temperature until it is saturated. The molar analysis of the saturated air and the density of air before and after the process are to be determined.

Assumptions The air and the water vapor are ideal gases.

Properties The molar masses of N_2, O_2, Ar, and H_2O are 28.0, 32.0, 39.9 and 18 kg / kmol, respectively (Table A-1). The molar analysis of dry air is given to be 78.1 percent N_2, 20.9 percent O_2, and 1 percent Ar. The saturation pressure of water at 25°C is 3.169 kPa (Table A-9). Also, 1 atm = 101.325 kPa.

Analysis (*a*) Noting that the total pressure remains constant at 101.32 kPa during this process, the partial pressure of air becomes

$$
\begin{aligned}
P &= P_{\text{air}} + P_{\text{vapor}} \\
P_{\text{air}} &= P - P_{\text{vapor}} \\
&= 101.325 - 3.169 = 98.156\,\text{kPa}
\end{aligned}
$$



Then the molar analysis of the saturated air becomes

$$
\begin{aligned}
y_{H_2O} &= \frac{P_{H_2O}}{P} = \frac{3.169}{101.325} = \mathbf{0.0313} \\
y_{N_2} &= \frac{P_{N_2}}{P} = \frac{y_{N_2,\text{dry}} P_{\text{dry air}}}{P} = \frac{0.781(98.156\text{ kPa})}{101.325} = \mathbf{0.7566} \\
y_{O_2} &= \frac{P_{O_2}}{P} = \frac{y_{O_2,\text{dry}} P_{\text{dry air}}}{P} = \frac{0.209(98.156\text{ kPa})}{101.325} = \mathbf{0.2025} \\
y_{\text{Ar}} &= \frac{P_{\text{Ar}}}{P} = \frac{y_{\text{Ar,dry}} P_{\text{dry air}}}{P} = \frac{0.01(98.156\text{ kPa})}{101.325} = \mathbf{0.0097}
\end{aligned}
$$

(*b*) The molar masses of dry and saturated air are

$$M_{\text{dry air}} = \sum y_i M_i = 0.781 \times 28.0 + 0.209 \times 32.0 + 0.01 \times 39.9 = 29.0 \ \text{kg / kmol}$$

$$M_{\text{sat air}} = \sum y_i M_i = 0.7565 \times 28.0 + 0.2025 \times 32.0 + 0.0097 \times 39.9 + 0.0313 \times 18 = 28.62 \ \text{kg / kmol}$$

Then the densities of dry and saturated air are determined from the ideal gas relation to be

$$\rho_{\text{dry air}} = \frac{P}{(R_u / M_{\text{dry air}})T} = \frac{101.325\,\text{kPa}}{[(8.314\,\text{kPa}\cdot\text{m}^3/\text{kmol}\cdot\text{K})/29.0\,\text{kg/kmol}](25+273)\text{K}} = \mathbf{1.186\,kg/m^3}$$

$$\rho_{\text{sat air}} = \frac{P}{(R_u / M_{\text{sat air}})T} = \frac{101.325\,\text{kPa}}{[(8.314\,\text{kPa}\cdot\text{m}^3/\text{kmol}\cdot\text{K})/28.62\,\text{kg/kmol}](25+273)\text{K}} = \mathbf{1.170\,kg/m^3}$$

Discussion We conclude that the density of saturated air is less than that of the dry air, as expected. This is due to the molar mass of water being less than that of dry air.

14-127 A glass of water is left in a room. The mole fraction of the water vapor in the air at the water surface and far from the surface as well as the mole fraction of air in the water near the surface are to be determined when the water and the air are at the same temperature.

Assumptions **1** Both the air and water vapor are ideal gases. **2** Air is weakly soluble in water and thus Henry's law is applicable.

Properties The saturation pressure of water at 25°C is 3.169 kPa (Table A-9). Henry's constant for air dissolved in water at 25ºC (298 K) is given in Table 14-6 to be H = 71,200 bar. Molar masses of dry air and water are 29 and 18 kg/kmol, respectively (Table A-1).

Analysis (*a*) Noting that the relative humidity of air is 70%, the partial pressure of water vapor in the air far from the water surface will be

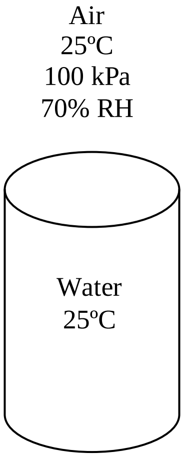
$$P_{\text{v,room air}} = \phi P_{\text{sat@25°C}} = (0.7)(3.169\text{ kPa}) = 2.218\text{ kPa}$$

Assuming both the air and vapor to be ideal gases, the mole fraction of water vapor in the room air is

$$y_{\text{vapor}} = \frac{P_{\text{vapor}}}{P} = \frac{2.218\text{ kPa}}{100\text{ kPa}} = \mathbf{0.0222} \quad \textbf{(or 2.22\%)}$$

(*b*) Noting that air at the water surface is saturated, the partial pressure of water vapor in the air near the surface will simply be the saturation pressure of water at 20°C, $P_{\text{v,interface}} = P_{sat@25°\text{C}} = 3.169\text{ kPa}$. Then the mole fraction of water vapor in the air at the interface becomes

$$y_{\text{v, surface}} = \frac{P_{\text{v, surface}}}{P} = \frac{3.169\text{ kPa}}{100\text{ kPa}} = \mathbf{0.0317} \quad \textbf{(or 3.17\%)}$$



(*c*) Noting that the total pressure is 100 kPa, the partial pressure of dry air at the water surface is

$$P_{\text{air, surface}} = P - P_{\text{v, surface}} = 100 - 3.169 = 96.831\text{ kPa}$$

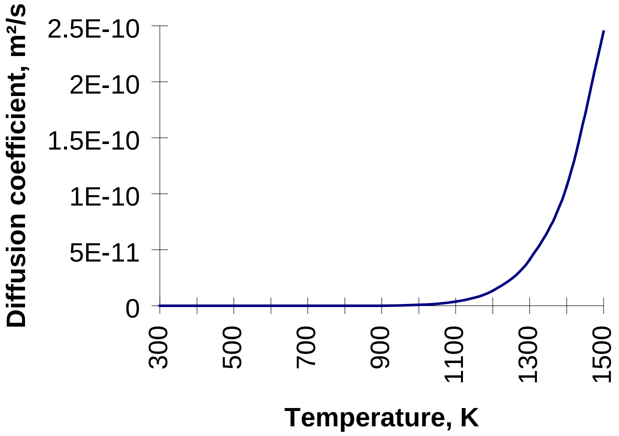
From Henry's law, the mole fraction of air in the water is determined to be

$$y_{\text{dry air,liquid side}} = \frac{P_{\text{dry air,gas side}}}{H} = \frac{(96.831/101.325)\text{ bar}}{71{,}200\text{ bar}} = \mathbf{1.34 \times 10^{-5}}$$

Discussion The water cannot remain at the room temperature when the air is not saturated. Therefore, some water will evaporate and the water temperature will drop until a balance is reached between the rate of heat transfer to the water and the rate of evaporation.

14-128 Using the relation $D_{AB} = 2.67 \times 10^{-5} \exp(-17{,}400 / T)$ the diffusion coefficient of carbon in steel is determined to be

T, K	D_{AB}, m^2 / s
300	1.728×10^{-30}
400	3.426×10^{-24}
500	2.056×10^{-20}
600	6.792×10^{-18}
700	4.277×10^{-16}
800	9.563×10^{-15}
900	1.071×10^{-13}
1000	7.409×10^{-13}
1100	3.604×10^{-12}
1200	1.347×10^{-11}
1300	4.108×10^{-11}
1400	1.068×10^{-10}
1500	2.440×10^{-10}



14-129 A 2-L bottle is filled with carbonated drink that is fully charged (saturated) with CO_2 gas. The volume that the CO_2 gas would occupy if it is released and stored in a container at room conditions is to be determined.

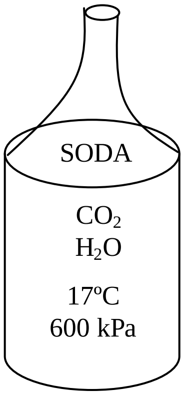
Assumptions **1** The liquid drink can be treated as water. **2** Both the CO_2 gas and the water vapor are ideal gases. **3** The CO_2 gas is weakly soluble in water and thus Henry's law is applicable.

Properties The saturation pressure of water at 17°C is 1.96 kPa (Table A-9). Henry's constant for CO_2 dissolved in water at 17ºC (290 K) is H = 1280 bar (Table 14-6). Molar masses of CO_2 and water are 44.01 and 18.015 kg/kmol, respectively (Table A-1). The gas constant of CO_2 is 0.1889 kPa.m^3/kg.K. Also, 1 bar = 100 kPa.

Analysis (*a*) In the charging station, the CO_2 gas and water vapor mixture above the liquid will form a saturated mixture. Noting that the saturation pressure of water at 17°C is 1.96 kPa, the partial pressure of the CO_2 gas is

$$P_{CO_2,\text{ gas side}} = P - P_{\text{vapor}} = P - P_{\text{sat@17°C}} = 600 - 1.96 = 598.04\text{ kPa} = 5.9804\text{ bar}$$

From Henry's law, the mole fraction of CO_2 in the liquid drink is determined to be



$$y_{CO_2,\text{liquid side}} = \frac{P_{CO_2,\text{gas side}}}{H} = \frac{5.9804\text{ bar}}{1280\text{ bar}} = 0.00467$$

Then the mole fraction of water in the drink becomes

$$y_{\text{water, liquid side}} = 1 - y_{CO_2,\text{ liquid side}} = 1 - 0.00467 = 0.99533$$

The mass and mole fractions of a mixture are related to each other by

$$w_i = \frac{m_i}{m_m} = \frac{N_i M_i}{N_m M_m} = y_i \frac{M_i}{M_m}$$

where the apparent molar mass of the drink (liquid water - CO_2 mixture) is

$$M_m = \sum y_i M_i = y_{\text{liquid water}} M_{\text{water}} + y_{CO_2} M_{CO_2} = 0.99533 \times 18.015 + 0.00467 \times 44.01 = 18.14\text{ kg/kmol}$$

Then the mass fraction of dissolved CO_2 in liquid drink becomes

$$w_{CO_2,\text{ liquid side}} = y_{CO_2,\text{ liquid side}}(0)\frac{M_{CO_2}}{M_m} = 0.00467\frac{44.01}{18.14} = 0.0113$$

Therefore, the mass of dissolved CO_2 in a 2 L ≈ 2 kg drink is

$$m_{CO_2} = w_{CO_2} m_m = 0.0113(2\text{ kg}) = 0.0226\text{ kg}$$

Then the volume occupied by this CO_2 at the room conditions of 25°C and 100 kPa becomes

$$V = \frac{mRT}{P} = \frac{(0.0226\text{ kg})(0.1889\text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(298\text{ K})}{100\text{ kPa}} = \mathbf{0.0127\ m^3} = \mathbf{12.7\ L}$$

Discussion Note that the amount of dissolved CO_2 in a 2-L pressurized drink is large enough to fill 6 such bottles at room temperature and pressure. Also, we could simplify the calculations by assuming the molar mass of carbonated drink to be the same as that of water, and take it to be 18 kg/kmol because of the very low mole fraction of CO_2 in the drink.

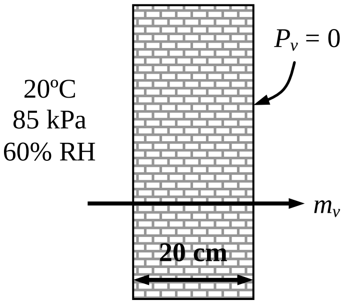
14-130 The walls of a house are made of 20-cm thick bricks. The maximum amount of water vapor that will diffuse through a 4 m × 7 m section of the wall in 24-h is to be determined.

ssumptions **1** Steady operating conditions exist. **2** Mass transfer through the wall is one-dimensional. **3** The vapor permeability of the wall is constant. **4** The vapor pressure at the outer side of the wall is zero.

Properties The permeance of the brick wall is given to be 23×10^{-12} kg/s.m^2.Pa. The saturation pressure of water at 20ºC is 2339 Pa (Table 14-9).

Analysis The mass flow rate of water vapor through a plain layer of thickness *L* and normal area *A* is given by (Eq. 14-31)

$$\dot{m}_v = \mathsf{P}A\frac{P_{v,1}-P_{v,2}}{L} = \mathsf{P}A\frac{\phi_1 P_{\text{sat},1}-\phi_2 P_{\text{sat},2}}{L} = \mathsf{M}A(\phi_1 P_{\text{sat},1}-\phi_2 P_{\text{sat},2})$$



where P is the vapor permeability and M = P/*L* is the permeance of the material, ϕ is the relative humidity and P_{sat} is the saturation pressure of water at the specified temperature. Subscripts 1 and 2 denote the air on the two sides of the wall.

Noting that the vapor pressure at the outer side of the wallboard is zero ($\phi_2 = 0$) and substituting, the mass flow rate of water vapor through the wall is determined to be

$$\dot{m}_v = (23\times10^{-12}\ \text{kg/s.m}^2\text{.Pa})(4\times7\ \text{m}^2)[0.60(2339\ \text{Pa})-0] = 9.038\times10^{-7}\ \text{kg/s}$$

Then the total amount of moisture that flows through the wall during a 24-h period becomes

$$m_{v,24-h} = \dot{m}_v\Delta t = (9.038\times10^{-7}\ \text{kg/s})(24\times3600\ \text{s}) = \mathbf{0.0781\,kg = 78.1\ g}$$

Discussion This is the maximum amount of moisture that can migrate through the wall since we assumed the vapor pressure on one side of the wall to be zero.

14-131E The thermal and vapor resistances of different layers of a wall are given. The rates of heat and moisture transfer through the wall under steady conditions are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat transfer through the wall is one-dimensional. **3** Thermal and vapor resistances of different layers of the wall and the heat transfer coefficients are constant. **4** Condensation does not occur inside the wall.

Properties The thermal and vapor resistances are as given in the problem statement. The saturation pressures of water at 70°F and 32°F are 0.3632 and 0.0887 psia, respectively (Table 14-9E).

Analysis Noting that all the layers of the wall are in series, the total thermal resistance of the wall for a 1-ft^2 section is determined by simply adding the R-values of all layers

$$R_{\text{total}} = \sum R\text{-value} = 0.17 + 0.43 + 0.10 + 4.20 + 1.02 + 0.45 + 0.68 = 7.05\ \text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F/Btu}$$

Then the rate of heat transfer through the entire wall becomes

$$\dot{Q}_{\text{wall}} = A\frac{T_i - T_o}{R_{\text{total}}} = (9\times 25\ \text{ft}^2)\frac{(70-32)^\circ\text{F}}{7.05\ \text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F / Btu}} = \mathbf{1436\ Btu\ /\ h}$$

The vapor pressures at the indoors and the outdoors is

$$P_{v,1} = \phi_1 P_{\text{sat},1} = 0.65\times(0.3632\ \text{psia}) = 0.2361\ \text{psia}$$
$$P_{v,2} = \phi_2 P_{\text{sat},2} = 0.40\times(0.0887\ \text{psia}) = 0.0355\ \text{psia}$$

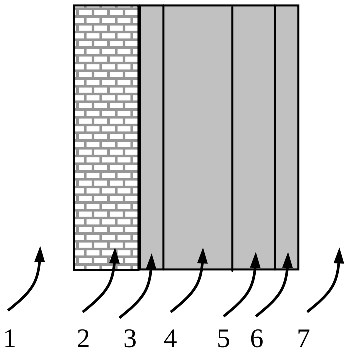
The total vapor resistance of the wall for a 1-ft^2 section is determined by simply adding the R$_v$-values of all layers,

$$R_{\text{v,total}} = \sum R_v - \text{value} = 15{,}000 + 1930 + 23{,}000 + 77.6 + 332 = 40{,}340\ \text{s}\cdot\text{ft}^2\cdot\text{psia / lbm}$$

Then the rate of moisture flow through the interior and exterior parts of the wall becomes

$$\dot{m}_{\text{v,wall}} = A\frac{P_{v,1} - P_{v,2}}{R_{\text{v,total}}} = (9\times 25\ \text{ft}^2)\frac{(0.2361 - 0.0355)\ \text{psia}}{40{,}340\ \text{s}\cdot\text{ft}^2\cdot\text{psia / lbm}} = 0.00112\ \text{lbm / s} = \mathbf{4.03\ lbm\ /\ h}$$

Construction	**R-value, h.ft^2.°F/Btu**	**R$_v$-value, s.ft^2.psi/lbm**
1. Outside surrface, 15 mph wind	0.17	-
2. Face brick, 4 in.	0.43	15,000
3. Cement mortar, 0.5 in.	0.10	1930
4. Concrete block, 6 in.	4.20	23,000
5. Air space, ¾ in.	1.02	77.6
6. Gypsum wallboard, 0.5 in.	0.45	332
7. Inside surface, still air	0.68	-



14-132 An aquarium is oxygenated by forcing air to the bottom of it. The mole fraction of water vapor is to be determined at the center of the air bubbles when they reach the free surface of water.

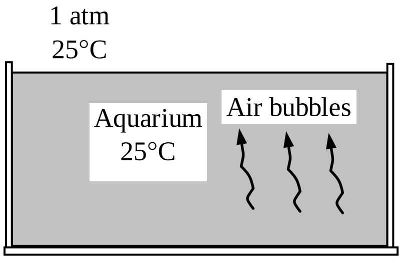
Assumptions **1** The air bubbles are initially completely dry. **2** The bubbles are spherical and possess symmetry about the midpoint. **3** Air is weakly soluble in water and thus Henry's law is applicable. **4** Convection effects in the bubble are negligible. **5** The pressure and temperature of the air bubbles remain constant at 1 atm and 25°C. **6** Both the air and the vapor are ideal gases.

Properties Henry's constant for oxygen dissolved in water at 300 K (≅ 25ºC) is given in Table 14-6 to be H = 43,600 bar. The saturation pressure of water at 25ºC is 3.169 kPa (Table A-9). The mass diffusivity of water vapor in air at 298 K is, from Eq. 14-15,

$$D_{AB}=D_{\mathrm{H_2O\text{-}air}}=1.87\times10^{-10}\frac{T^{2.072}}{P}=1.87\times10^{-10}\frac{(298\ \mathrm{K})^{2.072}}{1\ \mathrm{atm}}=2.50\times10^{-5}\ \mathrm{m^2/s}$$

Analysis This problem is analogous to the one-dimensional transient heat conduction problem in a sphere with specified surface temperature, and thus can be solved accordingly. Noting that the air in the bubble at the air-water interface will be saturated, the vapor pressure at the interface will be

$$P_{\mathrm{v,surface}}=P_{\mathrm{sat@25^\circ C}}=3.169\ \mathrm{kPa}$$



Then the mole fraction of vapor at the bubble interface becomes

$$y_{v,\ \mathrm{surface}}=\frac{P_{v,\mathrm{surface}}}{P}=\frac{3.169\ \mathrm{kPa}}{101.325\ \mathrm{kPa}}=0.0313$$

The mass transfer Fourier number for t = 2 s is

$$\tau=\frac{D_{AB}t}{r_0^2}=\frac{(2.50\times10^{-5}\ \mathrm{m^2}/s)(2\ \mathrm{s})}{(2\times10^{-3}\ \mathrm{m})}=12.5$$

Then the mole fraction of water vapor at the center of the bubble in 2 s can be determined from

$$\frac{y_{v,\mathrm{center}}-y_{v,\mathrm{surface}}}{y_{v,\ \mathrm{initial}}-y_{v,\ \mathrm{surface}}}=A_1\,e^{-\lambda_1^2\tau}$$

The Biot number Bi = hr_o/k in this case is infinity since a specified surface concentration corresponds to an infinitely large mass transfer coefficient ($h\to\infty$). Then the two constants in the equation above are determined from Table 4-1 to be λ_1 = 3.1416 and A_1 = 2. Also, $y_{v,\mathrm{initial}}=0$ since the air is initially dry. Substituting, the mole fraction of water vapor at the center of the bubble in 2 s is determined to be

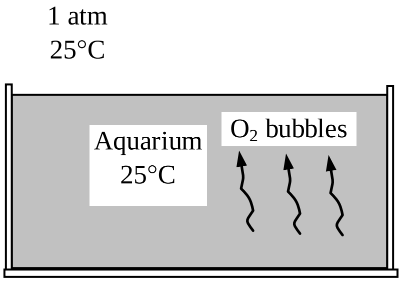
$$\frac{y_{v,\mathrm{center}}-0.0313}{0-0.0313}=2\,e^{-(3.1416)^2(12.5)}=5.27\times10^{-54}\cong0\ \rightarrow\ y_{v,\mathrm{center}}=y_{v,\mathrm{surface}}=\mathbf{0.0313}$$

That is, the air bubbles become saturated when they leave the aquarium.

14-133 An aquarium is oxygenated by forcing oxygen to the bottom of it, and letting the oxygen bubbles rise. The penetration depth of oxygen in the water during the rising time is to be determined.

Assumptions **1** Convection effects in the water are negligible. **2** The pressure and temperature of the oxygen bubbles remain constant.

Properties The mass diffusivity of oxygen in liquid water at 298 K is $D_{AB} = 2.5 \times 10^{-9}$ m²/s (Table 14-3b).



Analysis The penetration depth can be determined directly from its definition (Eq. 14-38) to be

$$\delta_{\text{diff}} = \sqrt{\pi D_{AB} t} = \sqrt{\pi (2.5\times 10^{-9}\text{ m}^2/\text{s})(2\text{ s})}$$
$$= 1.25\times 10^{-4}\text{ m} = \mathbf{0.125\ mm}$$

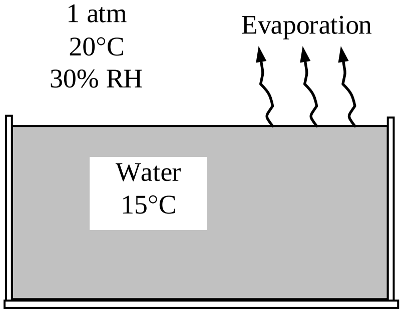
Therefore, oxygen will penetrate the water only a fraction of a milimeter.

14-134 A circular pan filled with water is cooled naturally. The rate of evaporation of water, the rate of heat transfer by natural convection, and the rate of heat supply to the water needed to maintain its temperature constant are to be determined.

Assumptions **1** The low mass flux model and thus the analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 25°C). **2** The critical Reynolds number for flow over a flat plate is 500,000. **3** Radiation heat transfer is negligible. **4** Both air and water vapor are ideal gases.

Properties The air-water vapor mixture is assumed to be dilute, and thus we can use dry air properties for the mixture at the average temperature of $(T_\infty + T_s)/2$ = (15+20)/2 = 17.5°C = 290.5 K. The properties of dry air at 290.5 K and 1 atm are, from Table A-15,

$$k = 0.0251\ \text{W/m}\cdot°\text{C},\quad \text{Pr} = 0.731$$
$$\alpha = 2.04\times 10^{-5}\ \text{m}^2\text{/s} \quad \nu = 1.49\times 10^{-5}\ \text{m}^2\text{/s}$$



The mass diffusivity of water vapor in air at the average temperature of 290.5 K is, from Eq. 14-15,

$$D_{AB} = D_{\text{H}_2\text{O-air}} = 1.87\times 10^{-10}\frac{T^{2.072}}{P}$$
$$= 1.87\times 10^{-10}\frac{(290.5\text{K})^{2.072}}{1\text{atm}} = 2.37\times 10^{-5}\ \text{m}^2\text{/s}$$

The saturation pressure of water at 20°C is $P_{\text{sat@20°C}} = 2.339$ kPa. Properties of water at 15°C are $h_{fg} = 2466$ kJ/kg and $P_v = 1.7051$ kPa (Table A-9). The specific heat of water at the average temperature of (15+20)/2 = 17.5°C is C_p = 4.184 kJ/kg.°C. The gas constants of dry air and water are R_{air} = 0.287 kPa.m^3/kg.K and R_{water} = 0.4615 kPa.m^3/kg.K (Table A-1).

Analysis (*a*) The air at the water surface is saturated, and thus the vapor pressure at the surface is simply the saturation pressure of water at the surface temperature (1.7051 kPa at 15°C). The vapor pressure of air far from the water surface is determined from

$$P_{v,\infty} = \phi P_{\text{sat@}T_\infty} = (0.30)P_{\text{sat@20°C}} = (0.30)(2.339\ \text{kPa}) = 0.7017\ \text{kPa}$$

Treating the water vapor and the air as ideal gases and noting that the total atmospheric pressure is the sum of the vapor and dry air pressures, the densities of the water vapor, dry air, and their mixture at the water-air interface and far from the surface are determined to be

At the surface:

$$\rho_{v,s} = \frac{P_{v,s}}{R_v T_s} = \frac{1.7051\ \text{kPa}}{(0.4615\ \text{kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(15+273)\ \text{K}} = 0.01283\ \text{kg/m}^3$$
$$\rho_{a,s} = \frac{P_{a,s}}{R_a T_s} = \frac{(101.325-1.7051)\ \text{kPa}}{(0.287\ \text{kPa.m}^3/\text{kg}\cdot\text{K})(15+273)\ \text{K}} = 1.2052\ \text{kg/m}^3$$
$$\rho_s = \rho_{v,s} + \rho_{a,s} = 0.01283 + 1.2052 = 1.21803\ \text{kg/m}^3$$

and

Away from the surface:

$$\rho_{v,\infty} = \frac{P_{v,\infty}}{R_v T_\infty} = \frac{0.7017\ \text{kPa}}{(0.4615\ \text{kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(20+273)\ \text{K}} = 0.00520\ \text{kg/m}^3$$
$$\rho_{a,\infty} = \frac{P_{a,\infty}}{R_a T_\infty} = \frac{(101.325-0.7017)\ \text{kPa}}{(0.287\ \text{kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(20+273\ \text{K})} = 1.1966\ \text{kg/m}^3$$
$$\rho_\infty = \rho_{v,\infty} + \rho_{a,\infty} = 0.0052 + 1.1966 = 1.2018\ \text{kg/m}^3$$

Note that $\rho_\infty < \rho_s$, and thus this corresponds to hot surface facing down. The area of the top surface of the water $A_s = \pi r_o^2$ and its perimeter is $p = 2\pi r_o$. Therefore, the characteristic length is

$$L = \frac{A_s}{p} = \frac{\pi r_o^2}{2\pi r_o} = \frac{r_o}{2} = \frac{0.15\,\text{m}}{2} = 0.075\,\text{m}$$

Then using densities (instead of temperatures) since the mixture is not homogeneous, the Grashoff number is determined to be

$$\text{Gr} = \frac{g(\rho_\infty - \rho_s)L^3}{\rho_\text{ave}\nu^2} = \frac{(9.81\,\text{m/s}^2)(1.2180 - 1.2018\,\text{kg/m}^3)(0.075\,\text{m})^3}{[(1.2180 + 1.2018)/2\,\text{kg/m}^3](1.49\times10^{-5}\,\text{m}^2/\text{s})^2} = 2.53\times10^5$$

Recognizing that this is a natural convection problem with cold horizontal surface facing up, the Nusselt number and the convection heat transfer coefficients are determined to be (Eq. 14-13)

$$\text{Nu} = 0.27(\text{Gr Pr})^{1/4} = 0.27(2.53\times10^5 \times 0.731)^{1/4} = 5.60$$

and

$$h_\text{conv} = \frac{\text{Nu}k}{L} = \frac{(5.60)(0.0250\,\text{W/m}\cdot{}^\circ\text{C})}{0.075\,\text{m}} = 1.87\,\text{W/m}^2\cdot{}^\circ\text{C}$$

Then the rate of heat transfer from the air to the water by forced convection becomes

$$\dot{Q}_\text{conv} = h_\text{conv}A_s(T_\infty - T_s) = (1.87\,\text{W/m}^2\cdot{}^\circ\text{C})[\pi(0.15\,\text{m})^2](20-15)^\circ\text{C} = \mathbf{0.66\,W} \quad \text{(to water)}$$

(*b*) Utilizing the analogy between heat and mass convection, the mass transfer coefficient is determined the same way by replacing Pr by Sc. The Schmidt number is determined from its definition to be

$$\text{Sc} = \frac{\nu}{D_{AB}} = \frac{1.49\times10^{-5}\,\text{m}^2/\text{s}}{2.37\times10^{-5}\,\text{m}^2/\text{s}} = 0.629$$

Therefore, the Sherwood number in this case is determined from Table 14-13 to be

$$\text{Sh} = 0.27(\text{GrSc})^{1/4} = 0.27(2.53\times10^5 \times 0.629)^{1/4} = 5.39$$

Using the definition of Sherwood number, the mass transfer coefficient is determined to be

$$h_\text{mass} = \frac{\text{Sh}D_{AB}}{L} = \frac{(5.39)(2.37\times10^{-5}\,\text{m}^2/\text{s})}{0.075\text{m}} = 0.00170\,\text{m/s}$$

Then the evaporation rate and the rate of heat transfer by evaporation become

$$\begin{aligned}\dot{m}_v &= h_\text{mass}A_s(\rho_{v,s} - \rho_{v,\infty}) = (0.00170\,\text{m/s})[\pi(0.15\,\text{m})^2](0.01283 - 0.00520)\,\text{kg/m}^3\\ &= 9.17\times10^{-7}\,\text{kg/s} = \mathbf{0.0033\,kg/h}\end{aligned}$$

and

$$\dot{Q}_\text{evap} = \dot{m}_v h_{fg} = (9.17\times10^{-7}\,\text{kg/s})(2466\,\text{kJ/kg}) = 0.00226\,\text{kW} = 2.26\,\text{W}$$

(*c*) The net rate of heat transfer to the water needed to maintain its temperature constant at 15°C is

$$\dot{Q}_\text{net} = \dot{Q}_\text{evap} + \dot{Q}_\text{conv} = 2.26 + (-0.66) = \mathbf{1.6\,W}$$

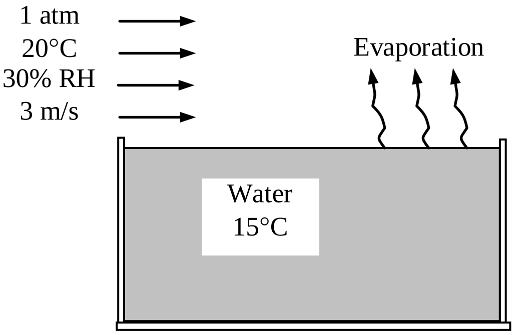
Discussion Note that if no heat is supplied to the water (by a resistance heater, for example), the temperature of the water in the pan would drop until the heat gain by convection equals the heat loss by evaporation.

14-135 Air is blown over a circular pan filled with water. The rate of evaporation of water, the rate of heat transfer by convection, and the rate of energy supply to the water to maintain its temperature constant are to be determined.

Assumptions **1** The low mass flux model and thus the analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 25°C). **2** The critical Reynolds number for flow over a flat plate is 500,000. **3** Radiation heat transfer is negligible. **4** Both air and water vapor are ideal gases.

Properties The air-water vapor mixture is assumed to be dilute, and thus we can use dry air properties for the mixture at the average temperature of $(T_\infty + T_s)/2$ = (15+20)/2 = 17.5°C = 290.5 K. The properties of dry air at 290.5 K and 1 atm are, from Table A-15,

$$k = 0.0251 \text{W/m}\cdot°\text{C}, \quad \text{Pr} = 0.731$$
$$\alpha = 2.04\times10^{-5}\text{ m}^2/\text{s} \quad \nu = 1.49\times10^{-5}\text{ m}^2/\text{s}$$



The mass diffusivity of water vapor in air at the average temperature of 290.5 K is, from Eq. 14-15,

$$D_{AB} = D_{\text{H}_2\text{O-air}} = 1.87\times10^{-10}\frac{T^{2.072}}{P}$$
$$= 1.87\times10^{-10}\frac{(290.5\text{ K})^{2.072}}{1\text{ atm}} = 2.37\times10^{-5}\text{ m}^2/\text{s}$$

The saturation pressure of water at 20°C is $P_{\text{sat@20°C}} = 2.339$ kPa. Properties of water at 15°C are $h_{fg} = 2466$ kJ/kg and $P_v = 1.7051$ kPa (Table A-9). Also, the gas constants of water is R_{water} = 0.4615 kPa.m^3/kg.K (Table A-1).

Analysis (*a*) Taking the radius of the pan r_0 = 0.15 m to be the characteristic length, the Reynolds number for flow over the pan is

$$\text{Re} = \frac{VL}{\nu} = \frac{(3\text{m/s})(0.15\text{ m})}{1.49\times10^{-5}\text{m}^2/\text{s}} = 30{,}201$$

which is less than 500,000, and thus the flow is laminar over the entire surface. The Nusselt number and the heat transfer coefficient are

$$\text{Nu} = 0.664\,\text{Re}_\text{L}^{0.5}\,\text{Pr}^{1/3} = 0.664(30{,}201)^{0.5}(0.731)^{1/3} = 103.9$$

$$h_\text{heat} = \frac{\text{Nu}k}{L} = \frac{(103.9)(0.0250\text{W/m}\cdot°\text{C})}{0.15\text{m}} = 17.3\text{W/m}^2\cdot°\text{C}$$

Then the rate of heat transfer from the air to the water by forced convection becomes

$$\dot{Q}_\text{conv} = h_\text{conv}A_s(T_\infty - T_s) = (17.3\text{ W/m}^2\cdot°\text{C})[\pi(0.15\text{ m})^2](20-15)°\text{C} = \mathbf{6.1\ W} \quad \text{(to water)}$$

(*b*) Utilizing the analogy between heat and mass convection, the mass transfer coefficient is determined the same way by replacing Pr by Sc. The Schmidt number is determined from its definition to be

$$\text{Sc} = \frac{\nu}{D_{AB}} = \frac{1.49\times10^{-5}\text{ m}^2/\text{s}}{2.37\times10^{-5}\text{ m}^2/\text{s}} = 0.629$$

Therefore, the Sherwood number in this case is determined from Table 14-13 to be

$$\text{Sh} = 0.664\,\text{Re}_\text{L}^{0.5}\,\text{Sc}^{1/3} = 0.664(30{,}201)^{0.5}(0.629)^{1/3} = 98.9$$

Using the definition of Sherwood number, the mass transfer coefficient is determined to be

$$h_\text{mass} = \frac{\text{Sh}D_{AB}}{L} = \frac{(98.9)(2.37\times10^{-5}\text{ m}^2/\text{s})}{0.15\text{m}} = 0.0156\text{ m/s}$$

The air at the water surface is saturated, and thus the vapor pressure at the surface is simply the saturation pressure of water at the surface temperature (1.7051 kPa at 15°C). The vapor pressure of air far from the water surface is determined from

$$P_{v,\infty} = \phi P_{\text{sat@}T_\infty} = (0.30)P_{\text{sat@20°C}} = (0.30)(2.339\text{ kPa}) = 0.7017\text{ kPa}$$

Treating the water vapor and the air as ideal gases, the vapor densities at the water-air interface and far from the surface are determined to be

At the surface:
$$\rho_{v,s} = \frac{P_{v,s}}{R_v T_s} = \frac{1.7051\text{ kPa}}{(0.4615\text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(15+273)\text{ K}} = 0.01283\text{ kg/m}^3$$

Away from the surface:
$$\rho_{v,\infty} = \frac{P_{v,\infty}}{R_v T_\infty} = \frac{0.7017\text{ kPa}}{(0.4615\text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(20+273)\text{ K}} = 0.00520\text{ kg/m}^3$$

Then the evaporation rate and the rate of heat transfer by evaporation become

$$\begin{aligned}\dot m_v &= h_{\text{mass}} A_s(\rho_{v,s}-\rho_{v,\infty}) = (0.0156\text{ m/s})[\pi(0.15\text{ m})^2](0.01283-0.00520)\text{ kg/m}^3 \\ &= 8.41\times10^{-6}\text{ kg/s} = \mathbf{0.0303\text{ kg/h}}\end{aligned}$$

and

$$\dot Q_{\text{evap}} = \dot m_v h_{fg} = (8.41\times10^{-6}\text{ kg/s})(2466\text{ kJ/kg}) = 0.0207\text{ kW} = 20.7\text{ W}$$

(*c*) The net rate of heat transfer to the water needed to maintain its temperature constant at 15°C is

$$\dot Q_{\text{net}} = \dot Q_{\text{evap}} + \dot Q_{\text{conv}} = 20.7 + (-6.1) = \mathbf{14.6\text{ W}}$$

Discussion Note that if no heat is supplied to the water (by a resistance heater, for example), the temperature of the water in the pan would drop until the heat gain by convection equals the heat loss by evaporation.

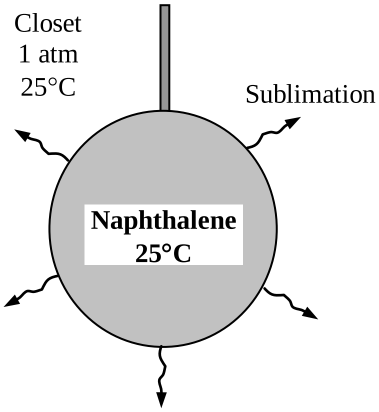
Also, the rate of evaporation could be determined almost as accurately using mass fractions of vapor instead of vapor fractions and the average air density from the relation $\dot m_{\text{evap}} = h_{\text{mass}}\rho A(w_{A,s} - w_{A,\infty})$.

14-136 A spherical naphthalene ball is hanged in a closet. The time it takes for the naphthalene to sublimate completely is to be determined.

Assumptions **1** The concentration of naphthalene in the air is very small, and the low mass flux conditions exist so that the Chilton-Colburn analogy between heat and mass transfer is applicable (will be verified). **2** Both air and naphthalene vapor are ideal gases. **3** The naphthalene and the surrounding air are at the same temperature. **4** The radiation effects are negligible.

Properties The molar mass of naphthalene is 128.2 kg/kmol. Because of low mass flux conditions, we can use dry air properties for the mixture at the specified temperature of 298 K and 1 atm, at which $\rho = 1.18\ \text{kg/m}^3$, $C_p = 1007\ \text{J/kg}\cdot\text{K}$, and $\alpha = 2.14\times10^{-5}\ \text{m}^2/\text{s}$ (Table A-15).

Analysis The incoming air is free of naphthalene, and thus the mass fraction of naphthalene at free stream conditions is zero, $w_{A,\infty} = 0$. Noting that the vapor pressure of naphthalene at the surface is 11 Pa, the mass fraction of naphthalene on the air side of the surface is



$$w_{A,s} = \frac{P_{A,s}}{P}\left(\frac{M_A}{M_{air}}\right) = \frac{11\text{Pa}}{101{,}325\,\text{Pa}}\left(\frac{128.2\,\text{kg/kmol}}{29\,\text{kg/kmol}}\right) = 4.8\times10^{-4}$$

Normally we would expect natural convection currents to develop around the naphthalene ball because the amount of naphthalene near the surface is much larger, and determine the Nusselt number (and its counterpart in mass transfer, the Sherwood number) from Eq. 14-16,

$$\text{Nu} = 2 + \frac{0.589\text{Ra}^{1/4}}{[1+(0.469/\text{Pr})^{9/16}]^{4/9}}$$

But the mass fraction value determined above indicates that the amount of naphthalene in the air is so low that it will not cause any significant difference in the density of air. With no density gradient, there will be no natural convection and thus the Rayleigh number can be taken to be zero. Then the Nusselt number relation above will reduce to Nu = 2 or its equivalent Sh = 2. Then using the definition of Sherwood number, the mass transfer coefficient can be expressed as

$$h_{\text{mass}} = \frac{\text{Sh}D_{AB}}{D} = \frac{2D_{AB}}{D}$$

The mass of naphthalene ball can be expressed as $m = \rho_{\text{naph}}V = \frac{1}{6}\rho_{\text{naph}}(\pi D^3)$. The rate of change of the mass of naphthalene is equal to the rate of mass transfer from naphthalene to the air, and is expressed as

$$\frac{dm}{dt} = -h_{\text{mass}}\rho_{\text{air}}A(w_{A,s} - w_{A,\infty})$$

$$\frac{d}{dt}\left(\frac{1}{6}\rho_{\text{naph}}(\pi D^3)\right) = -\frac{2D_{AB}}{D}\rho_{\text{air}}(\pi D^2)(w_{A,s} - w_{A,\infty})$$

$$\frac{3}{6}\pi\rho_{\text{naph}}D^2\frac{dD}{dt} = -2D_{AB}(\pi D)\rho_{\text{air}}(w_{A,s} - w_{A,\infty})$$

Simplifying and rearranging, $$DdD = -\frac{4\rho_{\text{air}}D_{AB}}{\rho_{\text{naph}}}(w_{A,s} - w_{A,\infty})dt$$

Integrating from $D = D_i = 0.03$ m at time $t = 0$ to $D = 0$ (complete sublimation) at time $t = t$ gives

$$t = \frac{\rho_{\text{naph}}D_i^2}{8\rho_{\text{air}}D_{AB}(w_{A,s} - w_{A,\infty})}$$

Substituting, the time it takes for the naphthalene to sublimate completely is determined to be

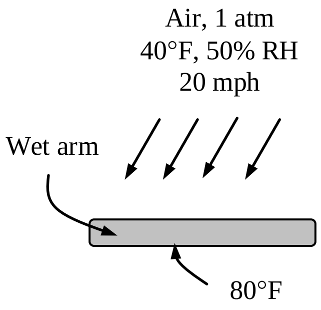
$$t = \frac{\rho_{\text{naph}}D_i^2}{8\rho_{\text{air}}D_{AB}(w_{A,s} - w_{A,\infty})} = \frac{(1100\ \text{kg/m}^3)(0.01\ \text{m})^2}{8(1.19\ \text{kg/m}^3)(4.80\times10^{-4} - 0)\ \text{m}^2/\text{s})} = 3.95\times10^6\ \text{s} = \mathbf{45.7\ days}$$

14-137E A swimmer extends his wet arms into the windy air outside. The rate at which water evaporates from both arms and the corresponding rate of heat transfer by evaporation are to be determined.

Assumptions **1** The low mass flux model and thus the analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 60°F). **2** The arm can be modeled as a long cylinder.

Properties Because of low mass flux conditions, we can use dry air properties for the mixture at the average temperature of (40 + 80)/2 = 60°F and 1 atm, for which $\nu = 0.159\times10^{-3}$ ft^2/s , and $\rho = 0.077$lbm / ft^3 (Table A-15E). The saturation pressure of water at 40ºF is 0.1217 psia. Also, at 80ºF, the saturation pressure is 0.5073 psia and the heat of vaporization is 1048 Btu/lbm (Table A-9E). The molar mass of water is R = 0.5956 psia.ft^3/lbm.R (Table A-1E). The mass diffusivity of water vapor in air at 60ºF = 520 R = 288.9 K is determined from Eq. 14-15 to be

$$D_{AB} = D_{\text{H}_2\text{O-air}} = 1.87\times10^{-10}\frac{T^{2.072}}{P} = 1.87\times10^{-10}\frac{(288.9\,\text{K})^{2.072}}{1\text{atm}} = 2.35\times10^{-5}\ \text{m}^2/\text{s} = 2.53\times10^{-4}\ \text{ft}^2/\text{s}$$



Analysis The Reynolds number for flow over a cylinder is

$$\text{Re} = \frac{VD}{\nu} = \frac{(20\times5280/3600\text{ft/s})(3/12\text{ ft})}{0.159\times10^{-3}\text{ ft}^2/\text{s}} = 46{,}120$$

The Schmidt number in this case is

$$\text{Sc} = \frac{\nu}{D_{AB}} = \frac{0.159\times10^{-3}\text{ ft}^2/\text{s}}{2.53\times10^{-4}\text{ ft}^2/\text{s}} = 0.628$$

Then utilizing the analogy between heat and mass convection, the Sherwood number is determined from Eq. 10-32 by replacing Pr number by the Schmidt number to be

$$\text{Sh} = 0.3 + \frac{0.62\,\text{Re}^{0.5}\,\text{Sc}^{1/3}}{\left[1+(0.4/\text{Sc})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{28200}\right)^{5/8}\right]^{4/5} = 0.3 + \frac{0.62(46{,}120)^{0.5}(0.628)^{1/3}}{\left[1+(0.4/0.628)^{2/3}\right]^{1/4}}\left[1+\left(\frac{46{,}120}{28200}\right)^{5/8}\right]^{4/5} = 198$$

Using the definition of Sherwood number, the mass transfer coefficient is determined to be

$$h_{\text{mass}} = \frac{\text{Sh}D_{AB}}{D} = \frac{(198)(2.53\times10^{-4}\text{ ft}^2/\text{s})}{3/12\,\text{ft}} = 0.2004\,\text{ft/s}$$

The air at the water surface is saturated, and thus the vapor pressure at the surface is simply the saturation pressure of water at the surface temperature (0.5073 psia at 80°F). The vapor pressure of air far from the water surface is determined from

$$P_{v,\infty} = \phi P_{\text{sat@}T_\infty} = (0.50)P_{\text{sat@40°F}} = (0.50)(0.1217\text{ psia}) = 0.0609\text{ psia}$$

Treating the water vapor as an ideal gas, the vapor densities at the water-air interface and far from the surface are determined to be

At the surface: $$\rho_{v,s} = \frac{P_{v,s}}{R_vT_s} = \frac{0.5073\text{ psia}}{(0.5956\text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(80+460)\text{ R}} = 0.00158\text{ lbm}/\text{ft}^3$$

Away from the surface: $$\rho_{v,\infty} = \frac{P_{v,\infty}}{R_vT_\infty} == \frac{0.0609\text{ psia}}{(0.5956\text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(40+460)\text{ R}} = 0.000205\text{ lbm}/\text{ft}^3$$

Then the evaporation rate and the rate of heat transfer by evaporation become

$$\dot{m}_v = h_{\text{mass}}A_s(\rho_{v,s} - \rho_{v,\infty}) = (0.2004\text{ ft/s})[2\times\pi(3/12\text{ ft})(2\text{ ft})](0.00158 - 0.000205)\text{ lbm/ft}^3$$
$$= 8.66\times10^{-4}\ \text{lbm/s} = \mathbf{3.12\ lbm/h}$$

and $\dot{Q}_{\text{evap}} = \dot{m}_v h_{fg} = (8.66\times10^{-4}\ \text{lbm/s})(1048\text{ Btu/lbm}) = \mathbf{0.907\ Btu/s}$

Discussion The rate of evaporation could be determined almost as accurately using mass fractions of vapor instead of vapor fractions and the average air density from the relation $\dot{m}_{\text{evap}} = h_{\text{mass}}\,\rho A(w_{A,s} - w_{A,\infty})$.

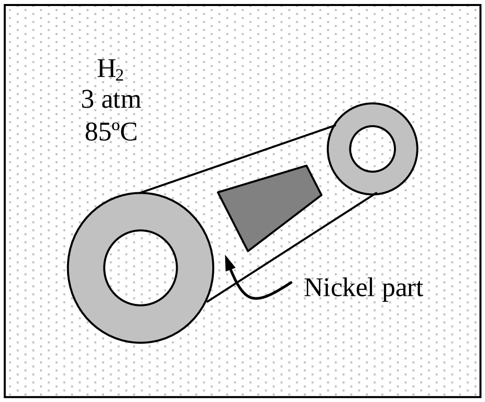
14-138 A nickel part is put into a room filled with hydrogen. The ratio of hydrogen concentrations at the surface of the part and at a depth of 2-mm from the surface after 24 h is to be determined.

Assumptions **1** Hydrogen penetrates into a thin layer beneath the surface of the nickel component, and thus the component can be modeled as a semi-infinite medium regardless of its thickness or shape. **2** The initial hydrogen concentration in the nickel part is zero.

Properties The molar mass of hydrogen H_2 is M = 2 kg/kmol (Table A-1). The solubility of hydrogen in nickel at 358 K (=85ºC) is 0.00901 kmol/m³.bar (Table 14-7). The mass diffusivity of hydrogen in nickel at 358 K is $D_{AB} = 1.2\times10^{-12}$ m^2/s (Table A-3b). Also, 1 atm = 1.01325 bar.

Analysis This problem is analogous to the one-dimensional transient heat conduction problem in a semi-infinite medium with specified surface temperature, and thus can be solved accordingly. Using mass fraction for concentration since the data is given in that form, the solution can be expressed as

$$\frac{w_A(x,t)-w_{A,i}}{w_{A,s}-w_{A,i}} = \operatorname{erfc}\left(\frac{x}{2\sqrt{D_{AB}t}}\right)$$



The molar density of hydrogen in the nickel at the interface is determined from Eq. 14-20 to be

$$\begin{aligned} C_{\mathrm{H_2,solid\ side}}(0) &= S\times P_{\mathrm{H_2,gas\ side}} \\ &= (0.00901\,\mathrm{kmol/m^3.bar})(3\times1.01325\ \mathrm{bar}) \\ &= 0.0274\ \mathrm{kmol/m^3} \end{aligned}$$

The argument of the complementary error function is

$$\xi = \frac{x}{2\sqrt{D_{AB}t}} = \frac{2\times10^{-3}\ \mathrm{m}}{2\sqrt{(1.2\times10^{-12}\ \mathrm{m^2/s})(24\times3600\ \mathrm{s})}} = 3.105$$

The corresponding value of the complementary error function is determined from Table 4-3 to be

$$\operatorname{erfc}\left(\frac{x}{2\sqrt{D_{AB}t}}\right) = \operatorname{erfc}(3.105) = 0.000015$$

Substituting the known quantities,

$$\frac{C_A(x,t)-0}{0.0274-0} = 0.000015 \quad\rightarrow\quad C_A(x,t) = \mathbf{4.1\times10^{-7}\ kmol/m^3}$$

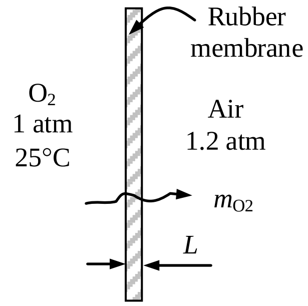
Therefore, the hydrogen concentration in the steel component at a depth of 2 mm in 24 h is very small.

14-139 A 0.1-mm thick soft rubber membrane separates pure O_2 from air. The mass flow rate of O_2 through the membrane per unit area and the direction of flow are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Mass transfer through the membrane is one-dimensional. **3** The permeability of the membrane is constant.

Properties The mass diffusivity of oxygen in rubber at 298 K is $D_{AB} = 2.1\times10^{-10}$ m^2/s (Table 11-3). The solubility of oxygen in rubber at 298 K is 0.00312 kmol / m³.bar (Table 14-7). The molar mass of oxygen is 32 kg / kmol (Table A-1).

Analysis The molar fraction of oxygen in air is 0.21. Therefore, the partial pressure of oxygen in the air is



$$y_{O_2} = \frac{P_{O_2,2}}{P} \rightarrow P_{O_2,2} = y_{O_2} P = 0.21\times(1.2\ \text{atm}) = 0.252\,\text{atm}$$

The partial pressure of oxygen on the other side is simply $P_{O_2,1} = 1$ atm. Then the molar flow rate of oxygen through the membrane by diffusion can readily be determined to be

$$\begin{aligned}\dot{N}_{\text{diff,A,wall}} &= D_{AB} S \frac{P_{A,1} - P_{A,2}}{L} \\ &= (2.1\times10^{-10}\ \text{m}^2/\text{s})(0.00312\,\text{kmol/m}^3.\text{bar})\frac{(1-0.252)\text{atm}}{0.1\times10^{-3}\ \text{m}}\left(\frac{1.01325\,\text{bar}}{1\,\text{atm}}\right) \\ &= 4.97\times10^{-9}\,\text{kmol/m}^2\cdot\text{s}\end{aligned}$$

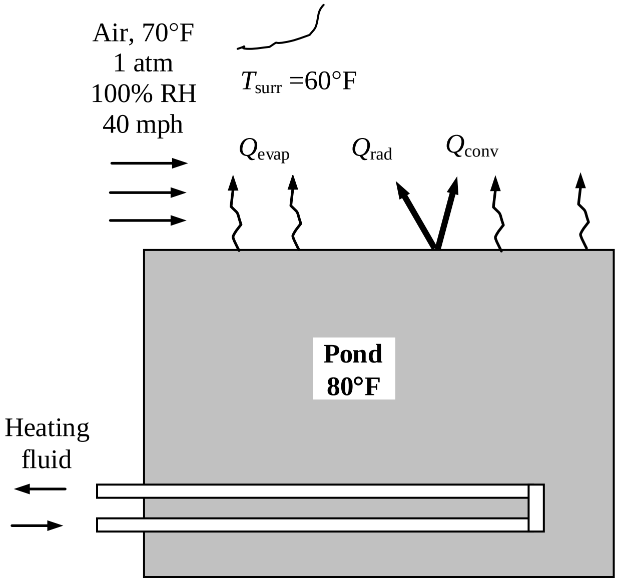
Then the mass flow rate of oxygen gas through the membrane becomes

$$\dot{m}_{\text{diff}} = M\dot{N}_{\text{diff}} = (32\ \text{kg/kmol})(4.97\times10^{-9}\ \text{kmol/m}^3.\text{s}) = \mathbf{1.59\times10^{-7}\ kg/m^2.s}$$

The direction of the flow will be from the pure oxygen inside to the air outside since the partial pressure of oxygen is higher inside.

14-140E The top section of a solar pond is maintained at a constant temperature. The rates of heat loss from the top surface of the pond by radiation, natural convection, and evaporation are to be determined.

Assumptions **1** The low mass flux conditions exist so that the Chilton-Colburn analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 80°F). **2** Both air and water vapor at specified conditions are ideal gases (the error involved in this assumption is less than 1 percent). **3** The water in the pool is maintained at a uniform temperature of 80°F. **4** The critical Reynolds number for flow over a flat surface is 500,000.



Properties The air-water vapor mixture is assumed to be dilute, and thus we can use dry air properties for the mixture at the average temperature of $(T_\infty + T_s)/2 =$ (70+80)/2 = 75°F. The properties of dry air at 75°F and 1 atm are, from Table A-15E,

$$k = 0.0147\,\text{Btu/h}\cdot\text{ft}\cdot°\text{F}$$
$$\text{Pr} = 0.73$$
$$\alpha = 0.824\,\text{ft}^2/\text{h}$$
$$\nu = 0.167\times10^{-3}\,\text{ft}^2/\text{s}$$

The saturation pressure of water at 70°F is $P_{\text{sat@70°F}} = 0.3632$ psia. Properties of water at 80°F are $h_{fg} = 1048\,\text{Btu/lbm}$ and $P_v = 0.5073\,\text{psia}$ (Table A-9). The gas constant of water is R_{water} = 0.5956 psia.ft^3/lbm.R (Table A-1E). The emissivity of water is 0.95 (Table A-15). The mass diffusivity of water vapor in air at the average temperature of 75°F = 535 R = 297.2 K is determined from Eq. 14-15 to be

$$D_{AB} = D_{\text{H}_2\text{O-air}} = 1.87\times10^{-10}\frac{T^{2.072}}{P} = 1.87\times10^{-10}\frac{(297.2\text{K})^{2.072}}{1\text{atm}} = 2.49\times10^{-5}\,\text{m}^2/\text{s} = 2.68\times10^{-4}\,\text{ft}^2/\text{s}$$

Analysis (*a*) The pond surface can be treated as a flat surface. The Reynolds number for flow over a flat surface is

$$\text{Re} = \frac{VL}{\nu} = \frac{(40\times5280/3600\text{ft/s})(100\,\text{ft})}{0.167\times10^{-3}\,\text{ft}^2/\text{s}} = 3.51\times10^7$$

which is much larger than the critical Reynolds number of 500,000. Therefore, the air flow over the pond surface is turbulent, and the Nusselt number and the heat transfer coefficient are determined to be

$$\text{Nu} = 0.037\,\text{Re}_\text{L}^{\,0.8}\,\text{Pr}^{1/3} = 0.037(3.51\times10^7)^{0.8}(0.73)^{1/3} = 36{,}215$$

$$h_{\text{heat}} = \frac{\text{Nu}k}{L} = \frac{(36{,}215)(0.0147\,\text{Btu/h}\cdot\text{ft}\cdot°\text{F})}{100\text{ft}} = 5.32\,\text{Btu/h}\cdot\text{ft}^2\cdot°\text{F}$$

Then the rate of heat transfer from the air to the water by forced convection becomes

$$\dot{Q}_{\text{conv}} = h_{\text{conv}}A_s(T_\infty - T_s) = (5.32\,\text{Btu/h}\cdot\text{ft}^2\cdot°\text{F})(10{,}000\,\text{ft}^2)(80-70)°\text{F} = \mathbf{532{,}000\,Btu/h} \quad \text{(to water)}$$

(*b*) Noting that the emissivity of water is 0.95 and the surface area of the pool is $A_s = (100\,\text{ft})(100\,\text{ft}) = 10{,}000\,\text{ft}^2$, heat transfer from the top surface of the pool by radiation is

$$\dot{Q}_{\text{rad}} = \varepsilon A_s \sigma (T_s^4 - T_{\text{surr}}^4) = (0.95)(10{,}000\ \text{ft}^2)(0.1714\times10^{-8}\ \text{Btu/h}\cdot\text{ft}^2\cdot\text{R}^4)[(540\ \text{R})^4 - (520\ \text{R})^4] = \mathbf{194{,}000\ Btu/h}$$

(*c*) Utilizing the analogy between heat and mass convection, the mass transfer coefficient is determined the same way by replacing Pr by Sc. The Schmidt number is determined from its definition to be

$$\text{Sc} = \frac{\nu}{D_{AB}} = \frac{0.167\times10^{-3}\ \text{ft}^2/\text{s}}{2.68\times10^{-4}\ \text{ft}^2/\text{s}} = 0.623$$

Then utilizing the analogy between heat and mass convection, the Sherwood number is determined by replacing Pr number by the Schmidt number to be

$$\text{Sh} = 0.037\,\text{Re}_{\text{L}}^{0.8}\text{Sc}^{1/3} = 0.037(3.51\times10^7)^{0.8}(0.623)^{1/3} = 34{,}350$$

Using the definition of Sherwood number, the mass transfer coefficient is determined to be

$$h_{\text{mass}} = \frac{\text{Sh}D_{AB}}{D} = \frac{(34{,}350)(2.68\times10^{-4}\ \text{ft}^2/\text{s})}{100\,\text{ft}} = 0.0921\text{ft/s}$$

The air at the water surface is saturated, and thus the vapor pressure at the surface is simply the saturation pressure of water at the surface temperature ($P_{\text{v,s}}$ = 0.5073 psia at 80°F). The humidity of air is given to be 100%, and thus the air far from the water surface is also saturated. Therefore, $P_{v,\infty} = P_{\text{sat@70°F}} = 0.3632$ psia.

Treating the water vapor as an ideal gas, the vapor densities at the water-air interface and far from the surface are determined to be

At the surface:
$$\rho_{v,s} = \frac{P_{v,s}}{R_v T_s} = \frac{0.5073\ \text{psia}}{(0.5956\ \text{psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(80+460)\ \text{R}} = 0.00158\ \text{lbm/ft}^3$$

Away from the surface:
$$\rho_{v,\infty} = \frac{P_{v,\infty}}{R_v T_\infty} == \frac{0.3632\ \text{psia}}{(0.5956\ \text{psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(70+460)\ \text{R}} = 0.00115\ \text{lbm/ft}^3$$

Then the evaporation rate and the rate of heat transfer by evaporation become

$$\begin{aligned}\dot{m}_v &= h_{\text{mass}} A_s(\rho_{v,s} - \rho_{v,\infty}) = (0.0921\,\text{ft/s})(10{,}000\,\text{ft}^2)(0.00158 - 0.00115)\ \text{lbm/ft}^3 \\ &= 0.396\ \text{lbm/s} = \mathbf{1426\ lbm/h}\end{aligned}$$

and

$$\dot{Q}_{\text{evap}} = \dot{m}_v h_{fg} = (1425\ \text{lbm/h})(1048\ \text{Btu/lbm}) = \mathbf{1{,}493{,}000\ Btu/h}$$

Discussion All of the quantities calculated above represent heat loss for the pond, and the total rate of heat loss from the open top surface of the pond to the surrounding air and surfaces is

$$\dot{Q}_{\text{total, top}} = \dot{Q}_{\text{rad}} + \dot{Q}_{\text{conv}} + \dot{Q}_{\text{evap}} = 194{,}000 + 532{,}000 + 1{,}493{,}000 = 2{,}219{,}000\ \text{Btu/h}$$

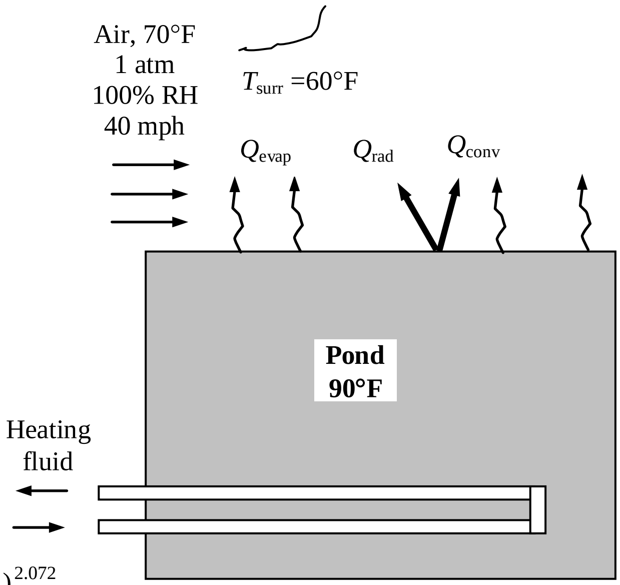
This heat loss will come from the deeper parts of the pond, and thus the pond will start cooling unless it gains heat from the sun or another heat source. Note that the evaporative heat losses dominate. Also, the rate of evaporation could be determined almost as accurately using mass fractions of vapor instead of vapor fractions and the average air density from the relation $\dot{m}_{\text{evap}} = h_{\text{mass}}\rho A_s(w_{A,s} - w_{A,\infty})$.

14-141E The top section of a solar pond is maintained at a constant temperature. The rates of heat loss from the top surface of the pond by radiation, natural convection, and evaporation are to be determined.

Assumptions **1** The low mass flux conditions exist so that the Chilton-Colburn analogy between heat and mass transfer is applicable since the mass fraction of vapor in the air is low (about 2 percent for saturated air at 80°F). **2** Both air and water vapor at specified conditions are ideal gases (the error involved in this assumption is less than 1 percent). **3** The water in the pool is maintained at a uniform temperature of 90°F. **4** The critical Reynolds number for flow over a flat surface is 500,000.

Properties The air-water vapor mixture is assumed to be dilute, and thus we can use dry air properties for the mixture at the average temperature of $(T_\infty + T_s)/2$ = (70+90)/2 = 80°F. The properties of dry air at 80°F and 1 atm are, from Table A-15E,

$$k = 0.0148\,\text{Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}$$
$$\text{Pr} = 0.73$$
$$\alpha = 0.838\,\text{ft}^2/\text{h}$$
$$\nu = 0.170\times10^{-3}\,\text{ft}^2/\text{s}$$



The saturation pressure of water at 70°F is $P_{\text{sat@70°F}} = 0.3632$ psia. Properties of water at 90°F are $h_{fg} = 1043$ Btu/lbm and $P_v = 0.6988$ psia (Table A-9). The gas constant of water is R_{water} = 0.5956 psia.ft^3/lbm.R (Table A-1E). The emissivity of water is 0.95 (Table A-15). The mass diffusivity of water vapor in air at the average temperature of 80°F = 540 R = 300 K is determined from Eq. 14-15 to be

$$D_{AB} = D_{\text{H}_2\text{O-air}} = 1.87\times10^{-10}\frac{T^{2.072}}{P} = 1.87\times10^{-10}\frac{(300\text{K})^{2.072}}{1\text{atm}} = 2.54\times10^{-5}\,\text{m}^2/\text{s} = 2.72\times10^{-4}\,\text{ft}^2/\text{s}$$

Analysis (*a*) The pond surface can be treated as a flat surface. The Reynolds number for flow over a flat surface is

$$\text{Re} = \frac{VL}{\nu} = \frac{(40\times5280/3600\,\text{ft/s})(100\,\text{ft})}{0.170\times10^{-3}\,\text{ft}^2/\text{s}} = 3.45\times10^7$$

which is much larger than the critical Reynolds number of 500,000. Therefore, the air flow over the pond surface is turbulent, and the Nusselt number and the heat transfer coefficient are determined to be

$$\text{Nu} = 0.037\,\text{Re}_L^{\,0.8}\,\text{Pr}^{1/3} = 0.037(3.45\times10^7)^{0.8}(0.73)^{1/3} = 35{,}720$$

$$h_{\text{heat}} = \frac{\text{Nu}k}{L} = \frac{(35{,}720)(0.0148\,\text{Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F})}{100\text{ft}} = 5.29\,\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$$

Then the rate of heat transfer from the air to the water by forced convection becomes

$$\dot{Q}_{\text{conv}} = h_{\text{conv}}A_s(T_\infty - T_s) = (5.29\,\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F})(10{,}000\,\text{ft}^2)(90-70)^\circ\text{F} = \mathbf{1{,}057{,}000\,Btu/h}\quad\text{(to water)}$$

(*b*) Noting that the emissivity of water is 0.95 and the surface area of the pool is $A_s = (100\,\text{ft})(100\,\text{ft}) = 10{,}000\,\text{ft}^2$, heat transfer from the top surface of the pool by radiation is

$$\dot{Q}_{\text{rad}} = \varepsilon A_s\sigma(T_s^4 - T_{\text{surr}}^4) = (0.95)(10{,}000\,\text{ft}^2)(0.1714\times10^{-8}\,\text{Btu/h}\cdot\text{ft}^2\cdot\text{R}^4)[(550\,\text{R})^4 - (520\,\text{R})^4] = \mathbf{299{,}400\,Btu/h}$$

(*c*) Utilizing the analogy between heat and mass convection, the mass transfer coefficient is determined the same way by replacing Pr by Sc. The Schmidt number is determined from its definition to be

$$\mathrm{Sc} = \frac{\nu}{D_{AB}} = \frac{0.170\times10^{-3}\ \mathrm{ft^2/s}}{2.72\times10^{-4}\ \mathrm{ft^2/s}} = 0.625$$

Then utilizing the analogy between heat and mass convection, the Sherwood number is determined by replacing Pr number by the Schmidt number to be

$$\mathrm{Sh} = 0.037\ \mathrm{Re_L}^{0.8}\,\mathrm{Sc}^{1/3} = 0.037(3.45\times10^7)^{0.8}(0.625)^{1/3} = 33{,}920$$

Using the definition of Sherwood number, the mass transfer coefficient is determined to be

$$h_{\mathrm{mass}} = \frac{\mathrm{Sh}D_{AB}}{D} = \frac{(33{,}920)(2.72\times10^{-4}\ \mathrm{ft^2/s})}{100\ \mathrm{ft}} = 0.0923\ \mathrm{ft/s}$$

The air at the water surface is saturated, and thus the vapor pressure at the surface is simply the saturation pressure of water at the surface temperature ($P_{\mathrm{v,s}}$ = 0.6988 psia at 90°F). The humidity of air is given to be 100%, and thus the air far from the water surface is also saturated. Therefore, $P_{v,\infty} = P_{\mathrm{sat@70°F}} = 0.3632$ psia.

Treating the water vapor as an ideal gas, the vapor densities at the water-air interface and far from the surface are determined to be

At the surface: $$\rho_{v,s} = \frac{P_{v,s}}{R_v T_s} = \frac{0.6988\ \mathrm{psia}}{(0.5956\ \mathrm{psia\cdot ft^3/lbm\cdot R})(90+460)\ \mathrm{R}} = 0.00213\ \mathrm{lbm/ft^3}$$

Away from the surface: $$\rho_{v,\infty} = \frac{P_{v,\infty}}{R_v T_\infty} == \frac{0.3632\ \mathrm{psia}}{(0.5956\ \mathrm{psia\cdot ft^3/lbm\cdot R})(70+460)\ \mathrm{R}} = 0.00115\ \mathrm{lbm/ft^3}$$

Then the evaporation rate and the rate of heat transfer by evaporation become

$$\begin{aligned}\dot m_v &= h_{\mathrm{mass}}A_s(\rho_{v,s}-\rho_{v,\infty}) = (0.0923\ \mathrm{ft/s})(10{,}000\ \mathrm{ft^2})(0.00213-0.00115)\ \mathrm{lbm/ft^3}\\ &= 0.905\ \mathrm{lbm/s} = \mathbf{3256\ lbm/h}\end{aligned}$$

and $$\dot Q_{\mathrm{evap}} = \dot m_v h_{fg} = (3256\ \mathrm{lbm/h})(1043\ \mathrm{Btu/lbm}) = \mathbf{3{,}396{,}000\ Btu/h}$$

Discussion All of the quantities calculated above represent heat loss for the pond, and the total rate of heat loss from the open top surface of the pond to the surrounding air and surfaces is

$$\dot Q_{\mathrm{total,\ top}} = \dot Q_{\mathrm{rad}} + \dot Q_{\mathrm{conv}} + \dot Q_{\mathrm{evap}} = 299{,}400 + 1{,}057{,}000 + 3{,}396{,}000 = 4{,}752{,}400\ \mathrm{Btu/h}$$

This heat loss will come from the deeper parts of the pond, and thus the pond will start cooling unless it gains heat from the sun or another heat source. Note that the evaporative heat losses dominate. Also, the rate of evaporation could be determined almost as accurately using mass fractions of vapor instead of vapor fractions and the average air density from the relation $\dot m_{\mathrm{evap}} = h_{\mathrm{mass}}\,\rho A(w_{A,s} - w_{A,\infty})$.

Chapter 15

COOLING OF ELECTRONIC EQUIPMENT

Introduction and History

15-1C The invention of vacuum diode started the electronic age. The invention of the transistor marked the beginning of a revolution in that age since the transistors performed the functions of the vacuum tubes with greater reliability while occupying negligible space and consuming negligible power compared to the vacuum tubes.

15-2C Integrated circuits are semiconductor devices in which several components such as diodes, transistors, resistors and capacitors are housed together. The initials MSI, LSI, and VLSI stand for medium scale integration, large scale integration, and very large scale integration, respectively.

15-3C The electrical resistance R is a measure of resistance against current flow, and the friction between the electrons and the material causes heating. The amount of the heat generated can be determined from Ohm's law, $W = I^2 R$.

15-4C The electrical energy consumed by the TV is eventually converted to heat, and the blanket wrapped around the TV prevents the heat from escaping. Then the temperature of the TV set will have to start rising as a result of heat build up. The TV set will have to burn up if operated this way for a long time. However, for short time periods, the temperature rise will not reach destructive levels.

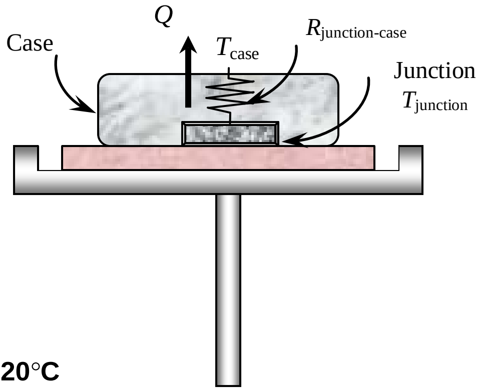
15-5C Since the heat generated in the incandescent light bulb which is completely wrapped can not escape, the temperature of the light bulb will increase, and will possibly start a fire by igniting the towel.

15-6C When the air flow to the radiator is blocked, the hot water coming off the engine cannot be cooled, and thus the engine will overheat and fail, and possible catch fire.

15-7C A car is much more likely to break since it has more moving parts than a TV.

15-8C Diffusion in semi-conductor materials, chemical reactions and creep in the bending materials cause electronic components to fail under prolonged use at high temperatures.

15-9 The case temperature of a power transistor and the junction-to-case resistance are given. The junction temperature is to be determined.



Assumptions Steady operating conditions exist.

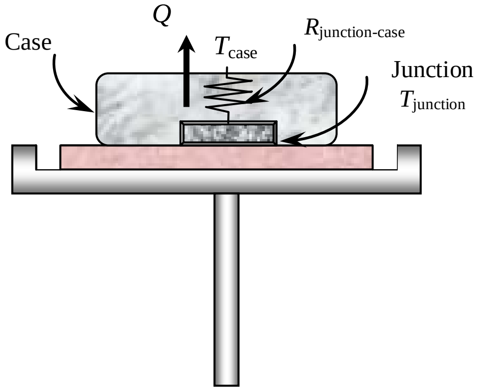
Analysis The rate of heat transfer between the junction and the case in steady operation is

$$\dot{Q} = \left(\frac{\Delta T}{R}\right)_{junction-case} = \frac{T_{junction} - T_{case}}{R_{junction-case}}$$

Then the junction temperature is determined to be

$$T_{junction} = T_{case} + \dot{Q}R_{junction-case} = 60°\text{C} + (12\text{ W})(5°\text{C/W}) = \mathbf{120°C}$$

15-10 The power dissipated by an electronic component as well as the junction and case temperatures are measured. The junction-to-case resistance is to be determined.



Assumptions Steady operating conditions exist.

Analysis The rate of heat transfer from the component is

$$\dot{W}_e = \dot{Q} = VI = (12\text{ V})(0.15\text{ A}) = 1.8\text{ W}$$

Then the junction-to-case thermal resistance of this component becomes

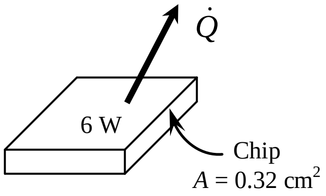
$$R_{junction-case} = \frac{T_{junction} - T_{case}}{\dot{Q}} = \frac{(80-55)°\text{C}}{1.8\text{ W}} = \mathbf{13.9°\ C\,/\,W}$$

15-11 A logic chip dissipates 6 W power. The amount of heat this chip dissipates during a 10-h period and the heat flux on the surface of the chip are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat transfer from the surface is uniform.

Analysis (*a*) The amount of heat this chip dissipates during an eight-hour workday is

$$Q = \dot{Q}\Delta t = (0.006\text{ kW})(8\text{ h}) = \mathbf{0.048\ kWh}$$



(*b*) The heat flux on the surface of the chip is

$$\dot{q} = \frac{\dot{Q}}{A} = \frac{6\text{ W}}{0.32\text{ cm}^2} = \mathbf{18.8\ W/cm^2}$$

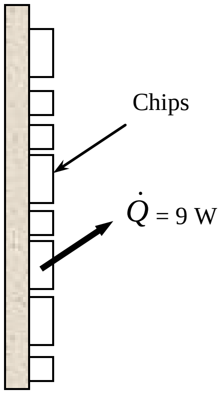
15-12 A circuit board houses 90 closely spaced logic chips, each dissipating 0.1 W. The amount of heat this chip dissipates in 10 h and the heat flux on the surface of the circuit board are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The heat transfer from the back surface of the board is negligible.

Analysis (*a*) The rate of heat transfer and the amount of heat this circuit board dissipates during a ten-hour period are

$$\dot{Q}_{total} = (90)(0.1\text{ W}) = 9\text{ W}$$

$$Q_{total} = \dot{Q}_{total}\Delta t = (0.009\text{ kW})(10\text{ h}) = \mathbf{0.09\ kWh}$$



(*b*) The average heat flux on the surface of the circuit board is

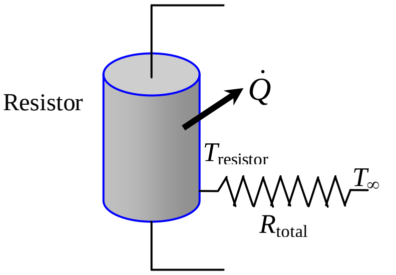
$$\dot{q} = \frac{\dot{Q}_{total}}{A_s} = \frac{9\text{ W}}{(15\text{ cm})(20\text{ cm})} = \mathbf{0.03\ W/cm^2}$$

15-13E The total thermal resistance and the temperature of a resistor are given. The power at which it can operate safely in a particular environment is to be determined.

Assumptions Steady operating conditions exist.

Analysis The power at which this resistor can be operate safely is determined from

$$\dot{Q} = \frac{T_{resistor} - T_{ambient}}{R_{total}} = \frac{(360-120)°\text{ F}}{130°\text{ F / W}} = \mathbf{1.85\ W}$$

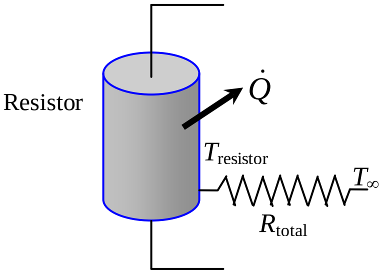


15-14 The surface-to-ambient thermal resistance and the surface temperature of a resistor are given. The power at which it can operate safely in a particular environment is to be determined.

Assumptions Steady operating conditions exist.

Analysis The power at which this resistor can operate safely is determined from

$$\dot{Q} = \frac{T_{resistor} - T_{ambient}}{R_{total}} = \frac{(150-30)°\text{C}}{300°\text{C/W}} = \mathbf{0.4\ W}$$



At specified conditions, the resistor dissipates

$$\dot{Q} = \frac{V^2}{R} = \frac{(7.5\text{ V})^2}{(100\ \Omega)} = 0.5625\text{ W}$$

of power. Therefore, the current operation is not safe.

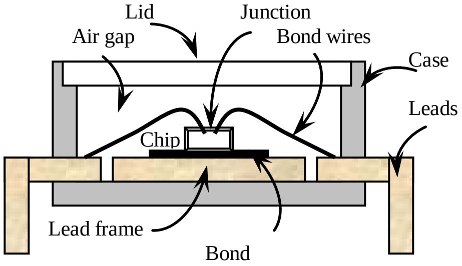
Manufacturing of Electronic Equipment

15-16C The thermal expansion coefficient of the plastic is about 20 times that of silicon. Therefore, bonding the silicon directly to the plastic case will result in such large thermal stresses that the reliability would be seriously jeopardized. To avoid this problem, a lead frame made of a copper alloy with a thermal expansion coefficient close to that of silicon is used as the bonding surface.

15-17C The schematic of chip carrier is given in the figure. Heat generated at the junction is transferred through the chip to the led frame, then through the case to the leads. From the leads heat is transferred to the ambient or to the medium the leads are connected to.



15-18C The cavity of the chip carrier is filled with a gas which is a poor conductor of heat. Also, the case is often made of materials which are also poor conductors of heat. This results in a relatively large thermal resistance between the chip and the case, called the junction-to-case thermal resistance. It depends on the geometry and the size of the chip carrier as well as the material properties of the bonding material and the case.

15-19C A hybrid chip carrier houses several chips, individual electronic components, and ordinary circuit elements connected to each other. The result is improved performance due to the shortening of the wiring lengths, and enhanced reliability. Lower cost would be an added benefit of multi-chip packages if they are produced in sufficiently large quantities.

15-20C A printed circuit board (PCB) is a properly wired plane board on which various electronic components such as the ICs, diodes, transistors, resistors, and capacitors are mounted to perform a certain task. The board of a PCB is made of polymers and glass epoxy materials. The thermal resistance between a device on the board and edge of the board is called as device-to-PCB edge thermal resistance. This resistance is usually high (about 20 to 60 $°\text{C/W}$) because of the low thickness of the board and the low thermal conductivity of the board material.

15-21C The three types of circuit boards are the single-sided, double-sided, and multi-layer boards. The single-sided PCBs have circuitry lines on one side of the board only, and are suitable for low density electronic devices (10-20 components). The double-sided PCBs have circuitry on both sides, and are best suited for intermediate density devices. Multi-layer PCBs contain several layers of circuitry, and they are suitable for high density devices. They are equivalent to several PCBs sandwiched together.

15-22C The desirable characteristics of the materials used in the fabrication of circuit boards are: (1) being an effective electrical insulator to prevent electrical breakdown, (2) being a good heat conductor to conduct the heat generated away, (3) having high material strength to withstand the forces and to maintain dimensional stability, (4) having a thermal expansion coefficient which closely matches to that of copper to prevent cracking in the copper cladding during thermal cycling, (5) having a high resistance to moisture absorption since moisture can effect both mechanical and electrical properties and degrade performance, (6) stability in properties at temperature levels encountered in electronic applications, (7) ready availability and manufacturability, and, of course (8) low cost.

15-23C An electronic enclosure (a case or a cabinet) house the circuit boards and the necessary peripheral equipment and connectors. It protects them from the detrimental effects of the environment, and may provide a cooling path. An electronic enclosure can simply be made of sheet metals such as thin gauge aluminum or steel.

Cooling Load of Electronic Equipment and Thermal Environment

15-24C The heating load of an electronic box which consumes 120 W of power is simply 120 W because of the conservation of energy principle.

15-25C Superconductor materials will generate hardly any heat and as a result, more components can be packed into a smaller volume, resulting in enhanced speed and reliability without having to resort to some exotic cooling techniques.

15-26C The actual power dissipated by a device can be considerably less than its rated power, depending on its duty cycle (the fraction of time it is on). A 5 W power transistor, for example, will dissipate an average of 2 W of power if it is active only 40 percent of the time. Then we can treat this transistor as a 2-W device when designing a cooling system. This may allow the selection of a simpler and cheaper cooling mechanism.

15-27C The cyclic variation of temperature of an electronic device during operation is called the temperature cycling. The thermal stresses caused by temperature cycling undermines the reliability of electronic devices. The failure rate of electronic devices subjected to deliberate temperature cycling of more than $20\,^\circ\mathrm{C}$ is observed to increase by eight-fold.

15-28C The ultimate heat sink for a TV is the room air with a temperature range of about 10 to 30°C. For an airplane it is the ambient air with a temperature range of about -50°C to 50°C. The ultimate heat sink for a ship is the sea water with a temperature range of 0°C to 30°C.

15-29C The ultimate heat sink for a VCR is the room air with a temperature range of about 10 to 30°C. For a spacecraft it is the ambient air or space with a temperature range of about -273°C to 50°C. The ultimate heat sink for a communication system on top of a mountain is the ambient air with a temperature range of about -20°C to 50°C.

Electronics Cooling in Different Applications

15-30C The electronics of short-range missiles do not need any cooling because of their short cruising times. The missiles reach their destinations before the electronics reach unsafe temperatures. The long-range missiles must be cooled because of their long cruise times (several hours). The electronics in this case are cooled by passing the liquid fuel they carry through the cold plate of the electronics enclosure as it flows towards the combustion chamber.

15-31C Dynamic temperature is the rise in the temperature of a fluid as a result of the ramming effect or the stagnation process. This is due to the conversion of kinetic energy to internal energy which is significant at high velocities. It is determined from $T_{dynamic} = V^2 / (2C_p)$ where V is the velocity and C_p is the specific heat of the fluid. It is significant at velocities above 100 m/s.

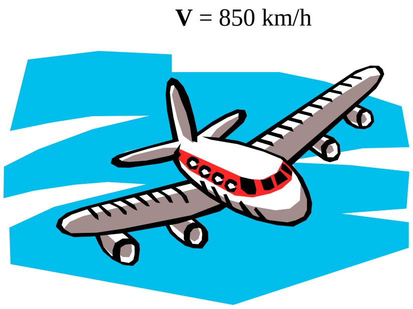
15-32C The electronic equipment in ships and submarines are usually housed in rugged cabinets to protect them from vibrations and shock during stormy weather. Because of easy access to water, water cooled heat exchangers are commonly used to cool sea-born electronics. Often air in a closed or open loop is cooled in an air-to-water heat exchanger, and is forced to the electronic cabinet by a fan.

15-33C The electronics of communication systems operate for long periods of time under adverse conditions such as rain, snow, high winds, solar radiation, high altitude, high humidity, and too high or too low temperatures. Large communication systems are housed in specially built shelters. Sometimes it is necessary to air-condition these shelters to safely dissipate the large quantities of heat generated by the electronics of communication systems.

15-34C The electronic components used in the high power microwave equipment such as radars generate enormous amounts of heat because of the low conversion efficiency of electrical energy to microwave energy. The klystron tubes of high power radar systems where radio frequency (RF) energy is generated can yield local heat fluxes as high as 2000 $\mathrm{W/cm^2}$. The safe and reliable dissipation of such high heat fluxes usually require the immersion of such equipment into a suitable dielectric fluid which can remove large quantities of heat by boiling.

15-35C The electronic equipment in space vehicles are usually cooled by a liquid circulated through the components where heat is picked up, and then through a space radiator where the waste heat is radiated into deep space at 0 K. In such systems it may be necessary to run a fan in the box to circulate the air since there is no natural convection currents in space because of the absence of a gravity field.

15-36 An airplane cruising in the air at a temperature of -25°C at a velocity of 850 km/h is considered. The temperature rise of air is to be determined.

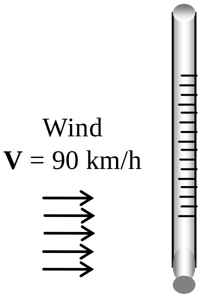


Assumptions Steady operating conditions exist.

Analysis The temperature rise of air (dynamic temperature) at this speed is

$$T_{dynamic}=\frac{V^2}{2C_p}=\frac{(850\times 1000/3600\text{ m/s})^2}{(2)(1003\text{ J/kg.°C})}\left(\frac{1\text{ J/kg}}{1\text{ m}^2/\text{s}^2}\right)=\mathbf{27.8°C}$$

15-37 The temperature of air in the wind at a wind velocity of 90 km/h is measured to be 12°C. The true temperature of air is to be determined.



Assumptions Steady operating conditions exist.

Analysis The temperature rise of air (dynamic temperature) at this speed is

$$T_{dynamic}=\frac{V^2}{2C_p}=\frac{(90\times 1000/3600\text{ m/s})^2}{(2)(1005\text{ J/kg.°C})}\left(\frac{1\text{ J/kg}}{1\text{ m}^2/\text{s}^2}\right)=\mathbf{0.3°C}$$

Therefore, the true temperature of air is

$$T_{true}=T_{measured}-T_{dynamic}=(12-0.3)°\text{C}=\mathbf{11.7°C}$$

15-39 Air at 25°C is flowing in a channel. The temperature a stationary probe inserted into the channel will read is to be determined for different air velocities.

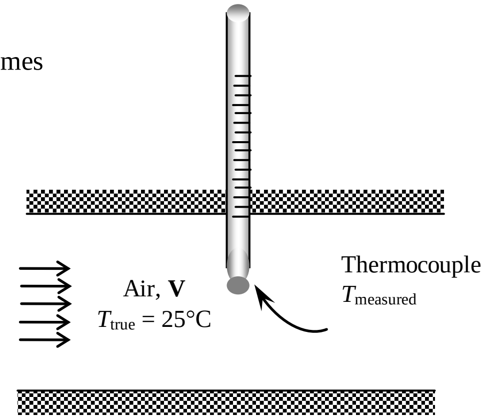
Assumptions Steady operating conditions exist.

Analysis (*a*) The temperature rise of air (dynamic temperature) for an air velocity of 1 m/s is

$$T_{dynamic} = \frac{\mathbf{V}^2}{2C_p} = \frac{(1\,\text{m/s})^2}{(2)(1005\,\text{J/kg.°C})}\left(\frac{1\,\text{J/kg}}{1\,\text{m}^2/\text{s}^2}\right) = 0.0005°\text{C}$$

Then the temperature which a stationary probe will read becomes

$$T_{measured} = T_{true} + T_{dynamic} = 25 + 0.0005 = \mathbf{25.0005°C}$$



(*b*) For an air velocity of 10 m/s the temperature rise is

$$T_{dynamic} = \frac{V^2}{2C_p} = \frac{(10\,\text{m/s})^2}{(2)(1005\,\text{J/kg.°C})}\left(\frac{1\,\text{J/kg}}{1\,\text{m}^2/\text{s}^2}\right) = 0.05°\text{C}$$

Then, $T_{measured} = T_{true} + T_{dynamic} = 25 + 0.05 = \mathbf{25.05°C}$

(*c*) For an air velocity of 100 m/s the temperature rise is

$$T_{dynamic} = \frac{V^2}{2C_p} = \frac{(100\,\text{m/s})^2}{(2)(1005\,\text{J/kg.°C})}\left(\frac{1\,\text{J/kg}}{1\,\text{m}^2/\text{s}^2}\right) = 4.98°\text{C}$$

Then, $T_{measured} = T_{true} + T_{dynamic} = 25 + 4.98 = \mathbf{29.98°C}$

(*d*) For an air velocity of 1000 m/s the temperature rise is

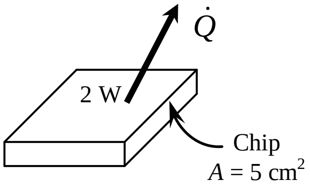
$$T_{dynamic} = \frac{V^2}{2C_p} = \frac{(1000\,\text{m/s})^2}{(2)(1005\,\text{J/kg.°C})}\left(\frac{1\,\text{J/kg}}{1\,\text{m}^2/\text{s}^2}\right) = 497.5°\text{C}$$

Then, $T_{measured} = T_{true} + T_{dynamic} = 25 + 497.5 = \mathbf{522.5°C}$

15-40 Power dissipated by an electronic device as well as its surface area and surface temperature are given. A suitable cooling technique for this device is to be determined.

Assumptions Steady operating conditions exist.

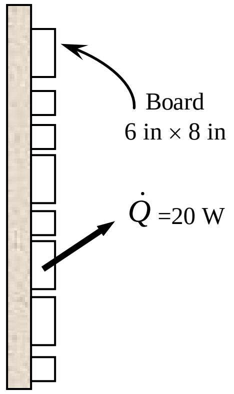
Analysis The heat flux on the surface of this electronic device is



$$\dot{q} = \frac{\dot{Q}}{A_s} = \frac{2\,\text{W}}{5\,\text{cm}^2} = \mathbf{0.4\ W/cm^2}$$

For an allowable temperature rise of 50°C, the suitable cooling technique for this device is determined from Fig. 15-17 to be **forced convection** with direct air.

15-41E Power dissipated by a circuit board as well as its surface area and surface temperature are given. A suitable cooling mechanism is to be selected.



Assumptions Steady operating conditions exist.

Analysis The heat flux on the surface of this electronic device is

$$\dot{q} = \frac{\dot{Q}}{A_s} = \frac{20\text{ W}}{(6\text{ in} \times 2.54\text{ cm/in})(8\text{ in} \times 2.54\text{ cm/in})} = \mathbf{0.065\ W/cm^2}$$

For an allowable temperature rise of 80°F, the suitable cooling technique for this device is determined from Fig. 15-17 to be **natural convection** with direct air.

Conduction Cooling

15-42C The major considerations in the selection of a cooling technique are the magnitude of the heat generated, the reliability requirements, the environmental conditions, and the cost.

15-43C Thermal resistance is the resistance of a materiel or device against heat flow through it. It is analogous to electrical resistance in electrical circuits, and the thermal resistance networks can be analyzed like electrical circuits.

15-44C If the rate of heat conduction through a medium $\dot{Q}$, and the thermal resistance R of the medium are known, then the temperature difference across the medium can be determined from $\Delta T = \dot{Q}R$.

15-45C The voltage drop across the wire is determined from $\Delta V = IR$. The length of the wire is proportional to the electrical resistance [$R = L/(\rho A)$], which is proportional to the voltage drop. Therefore, doubling the wire length while the current I is held constant will double the voltage drop.

The temperature drop across the wire is determined from $\Delta T = \dot{Q}R$. The length of the wire is proportional to the thermal resistance [$R = L/(kA)$], which is proportional to the temperature drop. Therefore, doubling the wire length while the heat flow Q is held constant will double the temperature drop.

15-46C A heat frame is a thick metal plate attached to a circuit board. It enhances heat transfer by providing a low resistance path for the heat flow from the circuit board to the heat sink. The thicker the heat frame, the lower the thermal resistance and thus the smaller the temperature difference between the center and the ends of the heat frame. The electronic components at the middle of a PCB operate at the highest temperature since they are furthest away from the heat sink.

15-47C Heat flow from the junction to the body of a chip is three-dimensional, but can be approximated as being one-dimensional by adding a constriction thermal resistance to the thermal resistance network. For a small heat generation area of diameter *a* on a considerably larger body, the constriction resistance is given by $R_{constriction} = 1/(2\sqrt{\pi}ak)$ where k is the thermal conductivity of the larger body. The constriction resistance is analogous to a partially closed valve in fluid flow, and a sudden drop in the cross-sectional area of an wire in electric flow.

15-48C The junction-to-case thermal resistance of an electronic component is the overall thermal resistance of all parts of the electronic component between the junction and case. In practice, this value is determined experimentally. When the junction-to-case resistance, the power dissipation, and the case temperature are known, the junction temperature of a component is determined from

$$T_{junctiion} = T_{case} + \dot{Q}R_{junction-case}$$

15-49C The case-to-ambient thermal resistance of an electronic device is the total thermal resistance of all parts of the electronic device between its outer surface and the ambient. In practice, this value is determined experimentally. Usually, manufacturers list the total resistance between the junction and the ambient for devices they manufacture for various configurations and ambient conditions likely to be encountered. When the case-to-ambient resistance, the power dissipation, and the ambient temperature are known, the junction temperature of the device is determined from $T_{junctiion} = T_{ambient} + \dot{Q}R_{junction-ambient}$

15-50C The junction temperature in this case is determined from

$$T_{junctiion} = T_{ambient} + \dot{Q}\left(R_{junction-case} + R_{case-ambient}\right).$$

When $R_{junction-case} > R_{case-ambient}$, the case temperature will be closer to the ambient temperature.

15-51C The PCBs are made of electrically insulating materials such as glass-epoxy laminates which are poor conductors of heat. Therefore, the rate of heat conduction along a PCB is very low. Heat conduction from the mid parts of a PCB to its outer edges can be improved by attaching heat frames or clamping cold plates to it. Heat conduction across the thickness of the PCB can be improved by planting copper or aluminum pins across the thickness of the PCB to serve as thermal bridges.

15-52C The thermal expansion coefficients of aluminum and copper are about twice as large as that of the epoxy-glass. This large difference in the thermal expansion coefficients can cause warping on the PCBs if the epoxy and the metal are not bonded properly. Warping is a major concern because it decreases reliability. One way of avoiding warping is to use PCBs with components on both sides.

15-53C The thermal conduction module received a lot of attention from thermal designers because the thermal design was incorporated at the initial stages of electrical design. The TCM was different from previous chip designs in that it incorporated both electrical and thermal considerations in early stages of design. The cavity in the TCM is filled with helium (instead of air) because of its very high thermal conductivity (about six times that of air).

15-54 The dimensions and power dissipation of a chip are given. The junction temperature of the chip is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat transfer through various components is one-dimensional. **3** Heat transfer through the air gap and the lid on top of the chip is negligible because of the very large thermal resistance involved along this path.

Analysis The various thermal resistances on the path of primary heat flow are

$$R_{constriction} = \frac{1}{2\sqrt{\pi a}k} = \frac{1}{2\sqrt{\pi}(0.5\times10^{-3}\text{ m})(120\text{ W/m.°C})} = 4.7\text{°C/W}$$

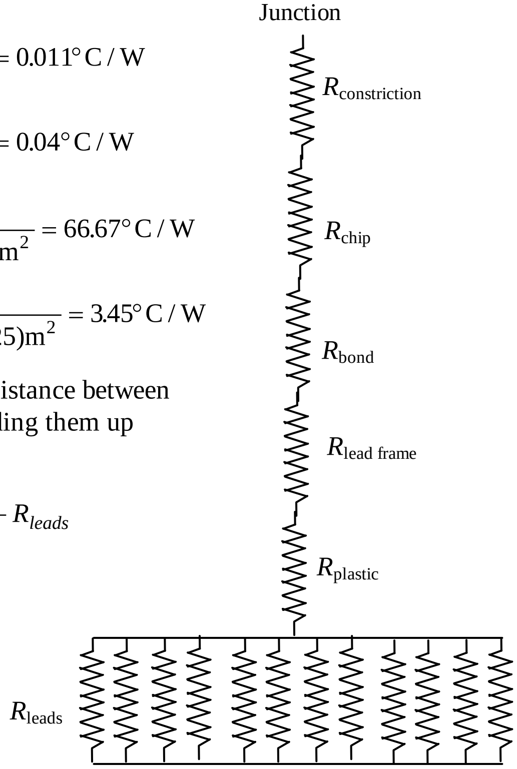
$$R_{chip} = \frac{L}{kA} = \frac{0.5\times10^{-3}\text{ m}}{(120\text{ W/m.°C})(0.004\times0.004)\text{m}^2} = 0.26\text{°C/W}$$

$$R_{bond} = \frac{L}{kA} = \frac{0.05\times10^{-3}\text{ m}}{(296\text{ W/m.°C})(0.004\times0.004)\text{m}^2} = 0.011\text{°C/W}$$

$$R_{\substack{lead\\frame}} = \frac{L}{kA} = \frac{0.25\times10^{-3}\text{ m}}{(386\text{ W/m.°C})(0.004\times0.004)\text{m}^2} = 0.04\text{°C/W}$$

$$R_{plastic} = \frac{L}{kA} = \frac{0.3\times10^{-3}\text{ m}}{(1\text{ W/m.°C})(18\times0.001\times0.00025)\text{m}^2} = 66.67\text{°C/W}$$

$$R_{leads} = \frac{L}{kA} = \frac{6\times10^{-3}\text{ m}}{(386\text{ W/m.°C})(18\times0.001\times0.00025)\text{m}^2} = 3.45\text{°C/W}$$



Since all resistances are in series, the total thermal resistance between the junction and the leads is determined by simply adding them up

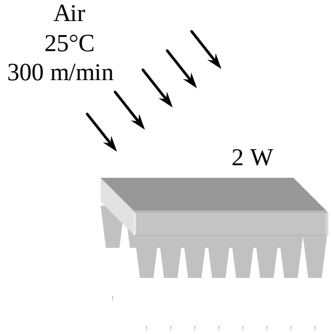
$$\begin{aligned} R_{total} &= R_{junction-lead} \\ &= R_{constriction} + R_{chip} + R_{bond} + R_{\substack{lead\\frame}} + R_{plastic} + R_{leads} \\ &= 4.7 + 0.26 + 0.011 + 0.04 + 66.67 + 3.45 \\ &= 75.13\text{°C/W} \end{aligned}$$

Knowing the junction-to-leads thermal resistance, the junction temperature is determined from

$$\dot{Q} = \frac{T_{junction} - T_{leads}}{R_{junction-case}}$$

$$T_{junction} = T_{leads} + \dot{Q}R_{junction-case} = 50\text{°C} + (0.8\text{ W})(75.13\text{°C/W}) = \mathbf{110.1\text{°C}}$$

15-55 A plastic DIP with 16 leads is cooled by forced air. Using data supplied by the manufacturer, the junction temperature is to be determined.



Assumptions Steady operating conditions exist.

Analysis The junction-to-ambient thermal resistance of the device with 16 leads corresponding to an air velocity of 300 m/min is determined from Fig.15-23 to be

$$R_{junction-ambient} = 50^\circ\text{C/W}$$

Then the junction temperature becomes

$$\dot{Q} = \frac{T_{junction} - T_{ambient}}{R_{junction-ambient}}$$

$$T_{junction} = T_{ambient} + \dot{Q}R_{junction-ambient} = 25^\circ\text{C} + (2\text{ W})(50^\circ\text{C/W}) = \mathbf{125^\circ C}$$

When the fan fails the total thermal resistance is determined from Fig.15-23 by reading the value for zero air velocity (the intersection point of the curve with the vertical axis) to be

$$R_{junction-ambient} = 70^\circ\text{C/W}$$

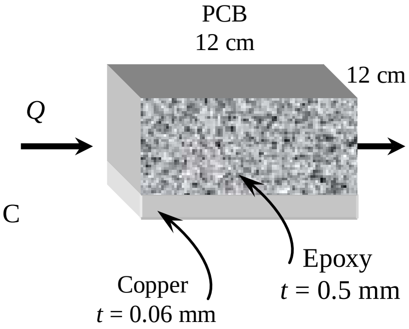
which yields

$$\dot{Q} = \frac{T_{junction} - T_{ambient}}{R_{junction-ambient}}$$

$$T_{junction} = T_{ambient} + \dot{Q}R_{junction-ambient} = 25^\circ\text{C} + (2\text{ W})(70^\circ\text{C/W}) = \mathbf{165^\circ C}$$

15-56 A PCB with copper cladding is given. The percentages of heat conduction along the copper and epoxy layers as well as the effective thermal conductivity of the PCB are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat conduction along the PCB is one-dimensional since heat transfer from side surfaces is negligible. **3** The thermal properties of epoxy and copper layers are constant.



Analysis Heat conduction along a layer is proportional to the thermal conductivity-thickness product (kt) which is determined for each layer and the entire PCB to be

$$(kt)_{copper} = (386\text{ W/m.}^\circ\text{C})(0.06\times10^{-3}\text{ m}) = 0.02316\text{ W/}^\circ\text{C}$$

$$(kt)_{epoxy} = (0.26\text{ W/m.}^\circ\text{C})(0.5\times10^{-3}\text{ m}) = 0.00013\text{ W/}^\circ\text{C}$$

$$(kt)_{PCB} = (kt)_{copper} + (kt)_{epoxy} = 0.02316 + 0.00013 = 0.02329\text{ W/}^\circ\text{C}$$

Therefore the percentages of heat conduction along the epoxy board are

$$f_{epoxy} = \frac{(kt)_{epoxy}}{(kt)_{PCB}} = \frac{0.00013\text{ W/}^\circ\text{C}}{0.02316\text{ W/}^\circ\text{C}} = 0.0056 \cong \mathbf{0.6\%}$$

and $f_{copper} = (100 - 0.6)\% = \mathbf{99.4\%}$

Then the effective thermal conductivity becomes

$$k_{eff} = \frac{(kt)_{epoxy} + (kt)_{copper}}{t_{epoxy} + t_{copper}} = \frac{(0.02316 + 0.00013)\text{ W/}^\circ\text{C}}{(0.06 + 0.5)\times10^{-3}\text{ m}} = \mathbf{41.6\ W/m.^\circ C}$$

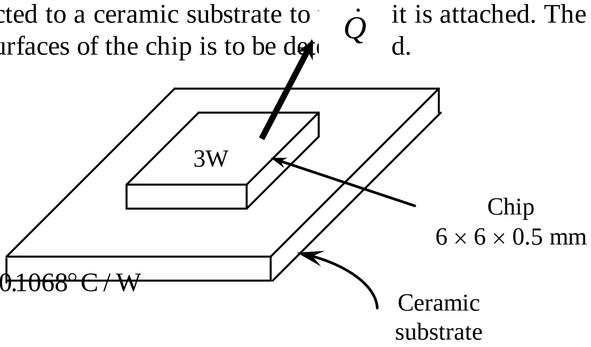
15-58 The heat generated in a silicon chip is conducted to a ceramic substrate to it is attached. The temperature difference between the front and back surfaces of the chip is to be de d.



Assumptions **1** Steady operating conditions exist. **2** Heat conduction along the chip is one-dimensional.

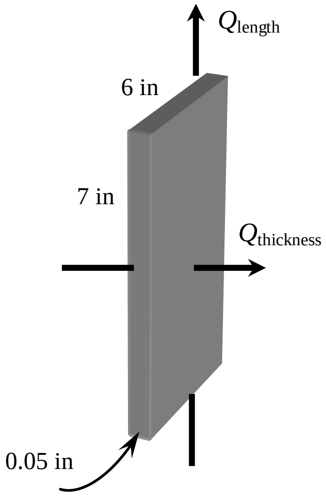
Analysis The thermal resistance of silicon chip is

$$R_{chip} = \frac{L}{kA} = \frac{0.5\times 10^{-3}\ \text{m}}{(130\ \text{W/m.°C})(0.006\times 0.006)\text{m}^2} = 0.1068\text{°C/W}$$

Then the temperature difference across the chip becomes

$$\Delta T = \dot{Q}R_{chip} = (3\ \text{W})(0.1068\text{°C/W}) = \mathbf{0.32°C}$$

15-59E The dimensions of an epoxy glass laminate are given. The thermal resistances for heat flow along the layers and across the thickness are to be determined.



Assumptions **1** Heat conduction in the laminate is one-dimensional in either case. **2** Thermal properties of the laminate are constant.

Analysis The thermal resistances of the PCB along the 7 in long side and across its thickness are

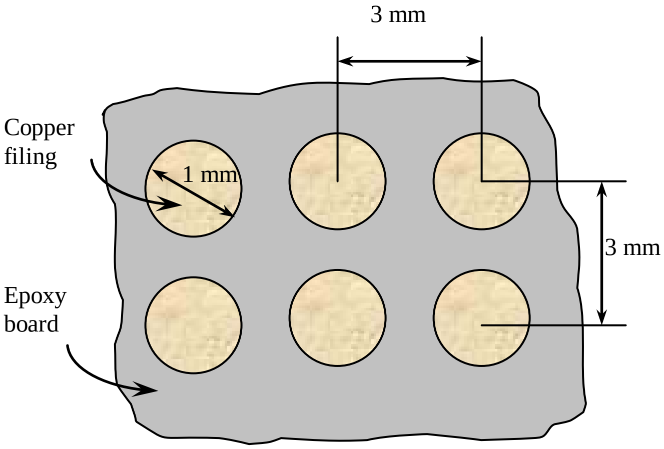
(*a*)

$$R_{\substack{along\\length}} = \frac{L}{kA} = \frac{(7/12)\ \text{ft}}{(0.15\ \text{Btu/h.ft.°F})(6/12\ \text{ft})(0.05/12\ \text{ft})} = \mathbf{1867\ h.°F/Btu}$$

(*b*)

$$R_{\substack{across\\thickness}} = \frac{L}{kA} = \frac{(0.05/12)\ \text{ft}}{(0.15\ \text{Btu/h.ft.°F})(7/12\ \text{ft})(6/12\ \text{ft})} = \mathbf{0.095\ h.°F/Btu}$$

15-60 Cylindrical copper fillings are planted throughout an epoxy glass board. The thermal resistance of the board across its thickness is to be determined.



Assumptions **1** Heat conduction along the board is one-dimensional. **2** Thermal properties of the board are constant.

Analysis The number of copper fillings on the board is

$$n = \frac{\text{Area of board}}{\text{Area of one square}} = \frac{(150\text{ mm})(180\text{ mm})}{(3\text{ mm})(3\text{ mm})} = 3000$$

The surface areas of the copper fillings and the remaining part of the epoxy layer are

$$A_{copper} = n\frac{\pi D^2}{4} = (3000)\frac{\pi(0.001\text{ m})^2}{4} = 0.002356\text{ m}^2$$

$$A_{total} = (length)(width) = (0.15\text{ m})(0.18\text{ m}) = 0.027\text{ m}^2$$

$$A_{epoxy} = A_{total} - A_{copper} = 0.027 - 0.002356 = 0.024644\text{ m}^2$$

The thermal resistance of each material is

$$R_{copper} = \frac{L}{kA} = \frac{0.0014\text{ m}}{(386\text{ W/m.°C})(0.002356\text{ m}^2)} = 0.00154\text{°C/W}$$

$$R_{epoxy} = \frac{L}{kA} = \frac{0.0014\text{ m}}{(0.26\text{ W/m.°C})(0.024644\text{ m}^2)} = 0.2185\text{°C/W}$$

Since these two resistances are in parallel, the equivalent thermal resistance of the entire board is

$$\frac{1}{R_{board}} = \frac{1}{R_{epoxy}} + \frac{1}{R_{copper}} = \frac{1}{0.2185\text{°C/W}} + \frac{1}{0.00154\text{°C/W}} \longrightarrow R_{board} = \mathbf{0.00153°C/W}$$

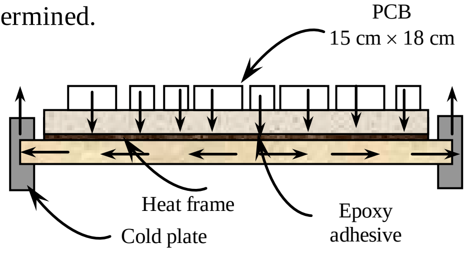
15-62 A circuit board with uniform heat generation is to be conduction cooled by a copper heat frame. Temperature distribution along the heat frame and the maximum temperature in the PCB are to be determined.



Assumptions **1** Steady operating conditions exist **2** Thermal properties are constant. **3** There is no direct heat dissipation from the surface of the PCB, and thus all the heat generated is conducted by the heat frame to the heat sink.

Analysis The properties and dimensions of various section of the PCB are summarized below as

Section and material	Thermal conductivity	Thickness	Heat transfer surface area
Epoxy board	0.26 W/m.°C	2 mm	10 mm × 120 mm
Epoxy adhesive	1.8 W/m.°C	0.12 mm	10 mm × 120 mm
Copper heat frame (normal to frame)	386 W/m.°C	1.5 mm	10 mm × 120 mm
Copper heat frame (along the frame)	386 W/m.°C	10 mm	15 mm × 120 mm

Using the values in the table, the various thermal resistances are determined to be

$$R_{epoxy}=\frac{L}{kA}=\frac{0.002\text{ m}}{(0.26\text{ W/m.}^\circ\text{C})(0.01\text{ m}\times 0.12\text{ m})}=6.41^\circ\text{C/W}$$

$$R_{adhesive}=\frac{L}{kA}=\frac{0.00012\text{ m}}{(1.8\text{ W/m.}^\circ\text{C})(0.01\text{ m}\times 0.12\text{ m})}=0.056^\circ\text{C/W}$$

$$R_{copper,\perp}=\frac{L}{kA}=\frac{0.0015\text{ m}}{(386\text{ W/m.}^\circ\text{C})(0.01\text{ m}\times 0.12\text{ m})}=0.0032^\circ\text{C/W}$$

$$R_{frame}=R_{copper,parallel}=\frac{L}{kA}=\frac{0.01\text{ m}}{(386\text{ W/m.}^\circ\text{C})(0.0015\times 0.12\text{ m})}=0.144^\circ\text{C/W}$$

The combined resistance between the electronic components on each strip and the heat frame can be determined by adding the three thermal resistances in series to be

$$R_{vertical}=R_{epoxy}+R_{adhesive}+R_{copper,\perp}=6.41+0.056+0.0032=6.469^\circ\text{C/W}$$

The temperatures along the heat frame can be determined from the relation $\Delta T=T_{high}-T_{low}=\dot{Q}R$. Then,

$$T_1=T_0+\dot{Q}_{1-0}R_{1-0}=30^\circ\text{C}+(22.5\text{ W})(0.144^\circ\text{C/W})=\mathbf{33.24^\circ C}$$

$$T_2=T_1+\dot{Q}_{2-1}R_{2-1}=33.24^\circ\text{C}+(19.5\text{ W})(0.144^\circ\text{C/W})=\mathbf{36.05^\circ C}$$

$$T_3=T_2+\dot{Q}_{3-2}R_{3-2}=36.05^\circ\text{C}+(16.5\text{ W})(0.144^\circ\text{C/W})=\mathbf{38.42^\circ C}$$

$$T_4=T_3+\dot{Q}_{4-3}R_{4-3}=38.42^\circ\text{C}+(13.5\text{ W})(0.144^\circ\text{C/W})=\mathbf{40.36^\circ C}$$

$$T_5=T_4+\dot{Q}_{5-4}R_{5-4}=40.36^\circ\text{C}+(10.5\text{ W})(0.144^\circ\text{C/W})=\mathbf{41.87^\circ C}$$

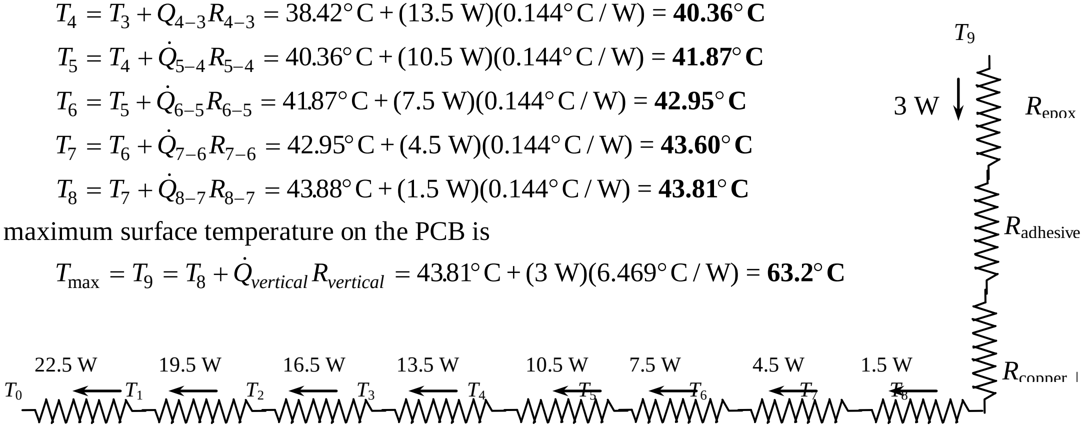
$$T_6=T_5+\dot{Q}_{6-5}R_{6-5}=41.87^\circ\text{C}+(7.5\text{ W})(0.144^\circ\text{C/W})=\mathbf{42.95^\circ C}$$

$$T_7=T_6+\dot{Q}_{7-6}R_{7-6}=42.95^\circ\text{C}+(4.5\text{ W})(0.144^\circ\text{C/W})=\mathbf{43.60^\circ C}$$

$$T_8=T_7+\dot{Q}_{8-7}R_{8-7}=43.88^\circ\text{C}+(1.5\text{ W})(0.144^\circ\text{C/W})=\mathbf{43.81^\circ C}$$

The maximum surface temperature on the PCB is

$$T_{\max}=T_9=T_8+\dot{Q}_{vertical}R_{vertical}=43.81^\circ\text{C}+(3\text{ W})(6.469^\circ\text{C/W})=\mathbf{63.2^\circ C}$$

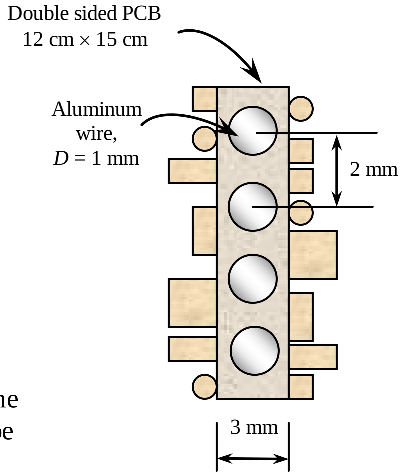


15-63 A circuit board with uniform heat generation is to be conduction cooled by aluminum wires inserted into it. The magnitude and location of the maximum temperature in the PCB is to be determined.

Assumptions **1** Steady operating conditions exist **2** Thermal properties are constant. **3** There is no direct heat dissipation from the surface of the PCB.

Analysis The number of wires in the board is

$$n = \frac{150 \text{ mm}}{2 \text{ mm}} = 75$$



The surface areas of the aluminum wires and the remaining part of the epoxy layer are

$$A_{aluminum} = n\frac{\pi D^2}{4} = (75)\frac{\pi(0.001 \text{ m})^2}{4} = 0.0000589 \text{ m}^2$$

$$A_{total} = (length)(width) = (0.003 \text{ m})(0.15 \text{ m}) = 0.00045 \text{ m}^2$$

$$A_{epoxy} = A_{total} - A_{aluminum} = 0.00045 - 0.0000589 = 0.0003911 \text{ m}^2$$

Considering only half of the circuit board because of symmetry, the thermal resistance of each material per 1-cm length is determined to be

$$R_{aluminum} = \frac{L}{kA} = \frac{0.01 \text{ m}}{(237 \text{ W/m.°C})(0.0000589 \text{ m}^2)} = 0.716\text{°C/W}$$

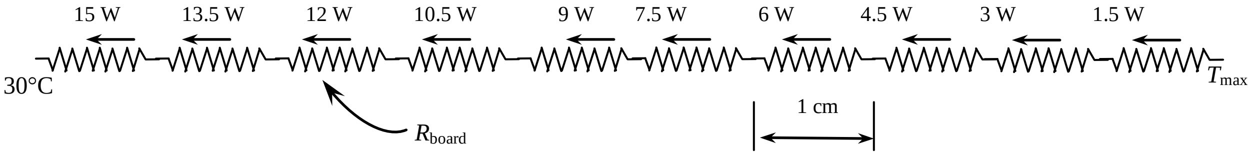
$$R_{epoxy} = \frac{L}{kA} = \frac{0.01 \text{ m}}{(0.26 \text{ W/m.°C})(0.0003911 \text{ m}^2)} = 98.34\text{°C/W}$$

Since these two resistances are in parallel, the equivalent thermal resistance per cm is determined from

$$\frac{1}{R_{board}} = \frac{1}{R_{epoxy}} + \frac{1}{R_{aluminum}} = \frac{1}{0.716\text{°C/W}} + \frac{1}{98.34\text{°C/W}} \longrightarrow R_{board} = 0.711\text{°C/W}$$

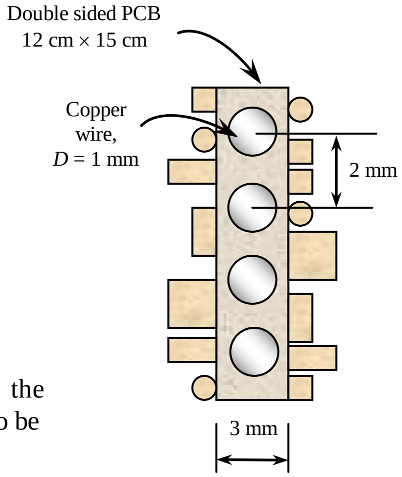
Maximum temperature occurs in the middle of the plate along the 20 cm length, which is determined to be

$$T_{\max} = T_{end} + \Delta T_{board,total} = T_{end} + \sum \dot{Q}_i R_{board,1-cm} = T_{end} + R_{board,1-cm}\sum \dot{Q}_i$$
$$= 30\text{°C} + (0.711\text{°C/W})(15+13.5+12+10.5+9+7.5+6+4.5+3+1.5)\text{W} = \mathbf{88.7\text{°C}}$$



15-64 A circuit board with uniform heat generation is to be conduction cooled by copper wires inserted in it. The magnitude and location of the maximum temperature in the PCB is to be determined.

Assumptions **1** Steady operating conditions exist **2** Thermal properties are constant. **3** There is no direct heat dissipation from the surface of the PCB.



Analysis The number of wires in the circuit board is

$$n = \frac{150\text{ mm}}{2\text{ mm}} = 75$$

The surface areas of the copper wires and the remaining part of the epoxy layer are

$$A_{copper} = n\frac{\pi D^2}{4} = (75)\frac{\pi(0.001\text{ m})^2}{4} = 0.0000589\text{ m}^2$$

$$A_{total} = (length)(width) = (0.003\text{ m})(0.15\text{ m}) = 0.00045\text{ m}^2$$

$$A_{epoxy} = A_{total} - A_{copper} = 0.00045 - 0.0000589 = 0.0003911\text{ m}^2$$

Considering only half of the circuit board because of symmetry, the thermal resistance of each material per 1-cm length is determined to be

$$R_{copper} = \frac{L}{kA} = \frac{0.01\text{ m}}{(386\text{ W/m.°C})(0.0000589\text{ m}^2)} = 0.440\text{°C/W}$$

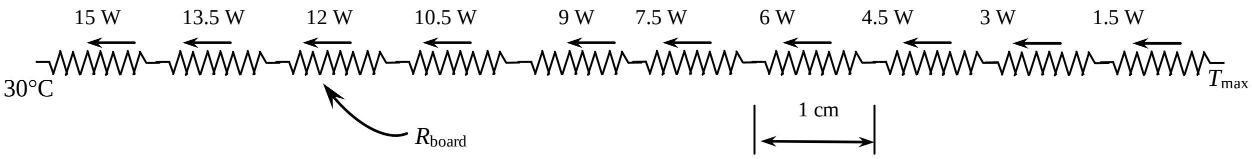
$$R_{epoxy} = \frac{L}{kA} = \frac{0.01\text{ m}}{(0.26\text{ W/m.°C})(0.0003911\text{ m}^2)} = 98.34\text{°C/W}$$

Since these two resistances are in parallel, the equivalent thermal resistance is determined from

$$\frac{1}{R_{board}} = \frac{1}{R_{epoxy}} + \frac{1}{R_{copper}} = \frac{1}{0.440\text{°C/W}} + \frac{1}{98.34\text{°C/W}} \longrightarrow R_{board} = 0.438\text{°C/W}$$

Maximum temperature occurs in the middle of the plate along the 20 cm length which is determined to be

$$T_{\max} = T_{end} + \Delta T_{board,total} = T_{end} + \sum \dot{Q}_i R_{board,1-cm} = T_{end} + R_{board,1-cm}\sum \dot{Q}_i$$
$$= 30\text{°C} + (0.438\text{°C/W})(15+13.5+12+10.5+9+7.5+6+4.5+3+1.5)\text{W} = \mathbf{66.1\text{°C}}$$

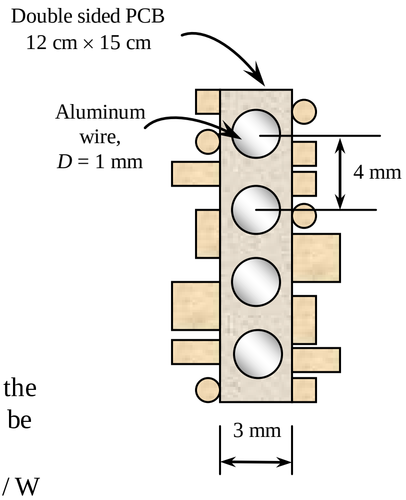


15-65 A circuit board with uniform heat generation is to be conduction cooled by aluminum wires inserted into it. The magnitude and location of the maximum temperature in the PCB is to be determined.

Assumptions **1** Steady operating conditions exist **2** Thermal properties are constant. **3** There is no direct heat dissipation from the surface of the PCB.

Analysis The number of wires in the board is

$$n = \frac{150\text{ mm}}{4\text{ mm}} = 37$$



The surface areas of the aluminum wires and the remaining part of the epoxy layer are

$$A_{aluminum} = n\frac{\pi D^2}{4} = (37)\frac{\pi(0.001\text{ m})^2}{4} = 0.000029\text{ m}^2$$

$$A_{total} = (length)(width) = (0.003\text{ m})(0.15\text{ m}) = 0.00045\text{ m}^2$$

$$A_{epoxy} = A_{total} - A_{aluminum} = 0.00045 - 0.000029 = 0.000421\text{ m}^2$$

Considering only half of the circuit board because of symmetry, the thermal resistance of each material per 1-cm length is determined to be

$$R_{aluminum} = \frac{L}{kA} = \frac{0.01\text{ m}}{(237\text{ W/m.°C})(0.000029\text{ m}^2)} = 1.455\text{°C/W}$$

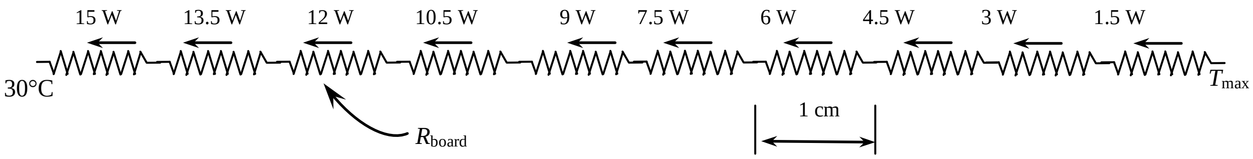
$$R_{epoxy} = \frac{L}{kA} = \frac{0.01\text{ m}}{(0.26\text{ W/m.°C})(0.000421\text{ m}^2)} = 91.36\text{°C/W}$$

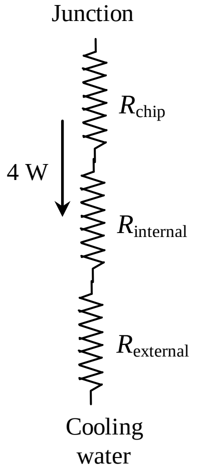
Since these two resistances are in parallel, the equivalent thermal resistance is determined from

$$\frac{1}{R_{board}} = \frac{1}{R_{epoxy}} + \frac{1}{R_{aluminum}} = \frac{1}{1.455\text{°C/W}} + \frac{1}{91.36\text{°C/W}} \longrightarrow R_{board} = 1.432\text{°C/W}$$

Maximum temperature occurs in the middle of the plate along the 20 cm length which is determined to be

$$\begin{aligned} T_{\max} &= T_{end} + \Delta T_{board,total} = T_{end} + \sum \dot{Q}_i R_{board,1-cm} = T_{end} + R_{board,1-cm}\sum \dot{Q}_i \\ &= 30\text{°C} + (1.432\text{°C/W})(15+13.5+12+10.5+9+7.5+6+4.5+3+1.5)\text{W} = \mathbf{148.1°C} \end{aligned}$$





15-66 A thermal conduction module with 80 chips is cooled by water. The junction temperature of the chip is to be determined.

Assumptions **1** Steady operating conditions exist **2** Heat transfer through various components is one-dimensional.

Analysis The total thermal resistance between the junction and cooling water is

$$R_{total} = R_{junction-water} = R_{chip} + R_{internal} + R_{external} = 1.2 + 9 + 7 = 17.2°\text{C}$$

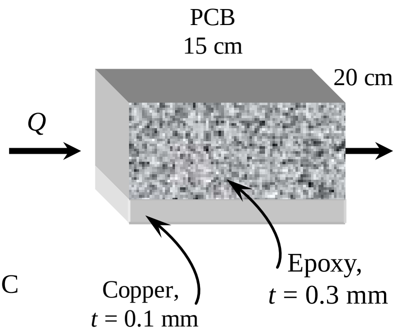
Then the junction temperature becomes

$$T_{junction} = T_{water} + \dot{Q}R_{junction-water} = 18°\text{C} + (4\text{ W})(17.2°\text{C/W}) = \mathbf{86.8°C}$$

15-67 A layer of copper is attached to the back surface of an epoxy board. The effective thermal conductivity of the board and the fraction of heat conducted through copper are to be determined.

Assumptions **1** Steady operating conditions exist **2** Heat transfer is one-dimensional.

Analysis Heat conduction along a layer is proportional to the thermal conductivity-thickness product (*kt*) which is determined for each layer and the entire PCB to be



$$(kt)_{copper} = (386\text{ W/m.°C})(0.0001\text{ m}) = 0.0386\text{ W/°C}$$

$$(kt)_{epoxy} = (0.26\text{ W/m.°C})(0.0003\text{ m}) = 0.000078\text{ W/°C}$$

$$(kt)_{PCB} = (kt)_{copper} + (kt)_{epoxy} = 0.0386 + 0.000078 = 0.038678\text{ W/°C}$$

The effective thermal conductivity can be determined from

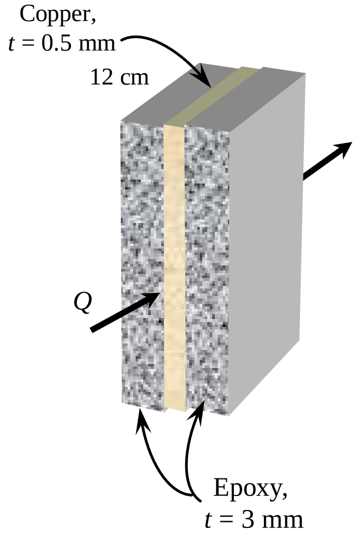
$$k_{eff} = \frac{(kt)_{epoxy} + (kt)_{copper}}{t_{epoxy} + t_{copper}} = \frac{(0.0386 + 0.000078)\text{ W/°C}}{(0.0003\text{ m} + 0.0001\text{ m})} = \mathbf{96.7\ W/m.°C}$$

Then the fraction of the heat conducted along the copper becomes

$$f = \frac{(kt)_{copper}}{(kt)_{PCB}} = \frac{0.0386\text{ W/°C}}{0.038678\text{ W/°C}} = 0.998 = \mathbf{99.8\%}$$

Discussion Note that heat is transferred almost entirely through the copper layer.

15-68 A copper plate is sandwiched between two epoxy boards. The effective thermal conductivity of the board and the fraction of heat conducted through copper are to be determined.



Assumptions **1** Steady operating conditions exist **2** Heat transfer is one-dimensional.

Analysis Heat conduction along a layer is proportional to the thermal conductivity-thickness product (kt) which is determined for each layer and the entire PCB to be

$$(kt)_{copper} = (386 \text{ W/m.°C})(0.0005 \text{ m}) = 0.193 \text{ W/°C}$$

$$(kt)_{epoxy} = (2)(0.26 \text{ W/m.°C})(0.003 \text{ m}) = 0.00156 \text{ W/°C}$$

$$(kt)_{PCB} = (kt)_{copper} + (kt)_{epoxy} = 0.193 + 0.00156 = 0.19456 \text{ W/°C}$$

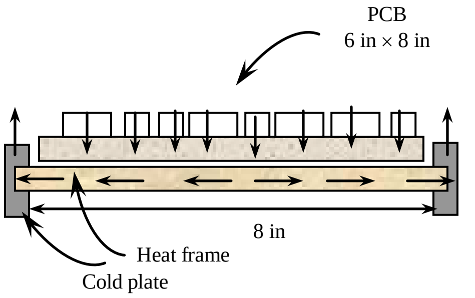
The effective thermal conductivity can be determined from

$$k_{eff} = \frac{(kt)_{epoxy} + (kt)_{copper}}{t_{epoxy} + t_{copper}} = \frac{(0.00156 + 0.193) \text{ W/°C}}{[(2 \times 0.003 \text{ m}) + 0.0005 \text{ m}]} = \mathbf{29.9 \text{ W/m.°C}}$$

Then the fraction of the heat conducted along the copper becomes

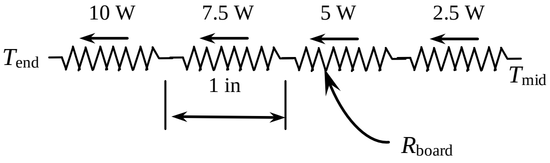
$$f = \frac{(kt)_{copper}}{(kt)_{PCB}} = \frac{0.193 \text{ W/°C}}{0.19456 \text{ W/°C}} = 0.992 = \mathbf{99.2\%}$$

15-69E A copper heat frame is used to conduct heat generated in a PCB. The temperature difference between the mid section and either end of the heat frame is to be determined.



Assumptions **1** Steady operating conditions exist **2** Heat transfer is one-dimensional.

Analysis We assume heat is generated uniformly on the 6 in × 8 in board, and all the heat generated is conducted by the heat frame along the 8-in side. Noting that the rate of heat transfer along the heat frame is variable, we consider 1 in × 8 in strips of the board. The rate of heat generation in each strip is (20 W)/8 = 2.5 W, and the thermal resistance along each strip of the heat frame is

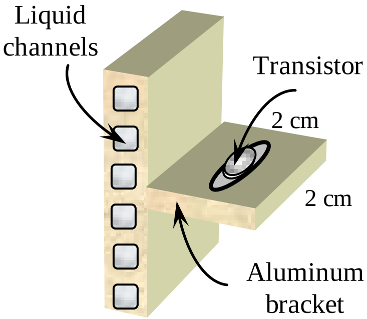


$$\begin{aligned} R_{frame} &= \frac{L}{kA} \\ &= \frac{(1/12) \text{ ft}}{(223 \text{ Btu/h.ft.°F})(6/12 \text{ ft})(0.06/12 \text{ ft})} \\ &= 0.149 \text{ h.°F/Btu} \end{aligned}$$

Maximum temperature occurs in the middle of the plate along the 20 cm length. Then the temperature difference between the mid section and either end of the heat frame becomes

$$\begin{aligned} \Delta T_{\max} &= \Delta T_{\text{mid section - edge of frame}} = \sum \dot{Q}_i R_{frame,1-in} = R_{frame,1-in} \sum \dot{Q}_i \\ &= (0.149\text{°F.h/Btu})(10 + 7.5 + 5 + 2.5 \text{ W})(3.4121 \text{ Btu/h.W}) = \mathbf{12.8°F} \end{aligned}$$

15-70 A power transistor is cooled by mounting it on an aluminum bracket that is attached to a liquid-cooled plate. The temperature of the transistor case is to be determined.



Assumptions **1** Steady operating conditions exist
2 Conduction heat transfer is one-dimensional.

Analysis The rate of heat transfer by conduction is

$$\dot{Q}_{conduction} = (0.80)(12\text{ W}) = 9.6\text{ W}$$

The thermal resistance of aluminum bracket and epoxy adhesive are

$$R_{aluminum} = \frac{L}{kA} = \frac{0.01\text{ m}}{(237\text{ W/m.}^\circ\text{C})(0.003\text{ m})(0.02\text{ m})} = 0.703^\circ\text{C/W}$$

$$R_{epoxy} = \frac{L}{kA} = \frac{0.0002\text{ m}}{(1.8\text{ W/m.}^\circ\text{C})(0.003\text{ m})(0.02\text{ m})} = 1.852^\circ\text{C/W}$$

The total thermal resistance between the transistor and the cold plate is

$$R_{total} = R_{case-cold\ plate} = R_{plastic} + R_{epoxy} + R_{aluminum} = 2.5 + 1.852 + 0.703 = 5.055^\circ\text{C/W}$$

Then the temperature of the transistor case is determined from

$$T_{case} = T_{\substack{cold\\plate}} + \dot{Q}R_{case-cold\ plate} = 50^\circ\text{C} + (9.6\text{ W})(5.055^\circ\text{C/W}) = \mathbf{98.5^\circ C}$$

Air Cooling: Natural Convection and Radiation

15-71C As the student watches the movie, the temperature of the electronic components in the VCR will keep increasing because of the blocked air passages. The VCR eventually may overheat and fail.

15-72C There is no natural convection in space because of the absence of gravity (and because of the absence of a medium outside). However, it can be cooled by radiation since radiation does not need a medium.

15-73C The openings on the side surfaces of a TV, VCR or other electronic enclosures provide passage ways for the cold air to enter and warm air to leave. If a TV or VCR is enclosed in a cabinet with no free space around, and if there is no other cooling process involved, the temperature of device will keep rising due to the heat generation in device, which may cause the device to fail eventually.

15-74C The magnitude of radiation, in general, is comparable to the magnitude of natural convection. Therefore, radiation heat transfer should be always considered in the analysis of natural convection cooled electronic equipment.

15-75C The effect of atmospheric pressure to heat transfer coefficient can be written as $h_{conv,P\,atm} = h_{conv,1\,atm}\sqrt{P}\quad (\mathrm{W/m^2.^\circ C})$ where P is the air pressure in atmosphere. Therefore, the greater the air pressure, the greater the heat transfer coefficient. The best and the worst orientation for heat transfer from a square surface are vertical and horizontal, respectively, since the former maximizes and the latter minimizes natural convection.

15-76C The view factor from surface 1 to surface 2 is the fraction of radiation which leaves surface 1 and strikes surface 2 directly. The magnitude of radiation heat transfer between two surfaces is proportional to the view factor. The larger the view factor, the larger the radiation exchange between the two surfaces.

15-77C Emissivity of a surface is the ratio of the radiation emitted by a surface at a specified temperature to the radiation emitted by a blackbody (which is the maximum amount) at the same temperature. The magnitude of radiation heat transfer between a surfaces and it surrounding surfaces is proportional to the emissivity. The larger the emissivity, the larger the radiation heat exchange between the two surfaces.

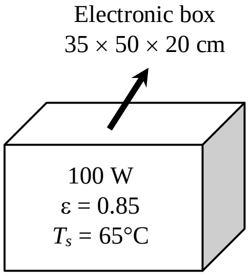
15-78C For most effective natural convection cooling of a PCB array, the PCB should be placed vertically to take advantage of natural convection currents which tend to rise naturally, and to minimize trapped air pockets. Placing the PCBs too close to each other tends to choke the flow because of the increased resistance. Therefore, the PCBs should be placed far from each other for effective heat transfer (A distance of about 2 cm between the PCBs turns out to be adequate for effective natural convection cooling.)

15-79C Radiation heat transfer from the components on the PCBs in an enclosure is negligible since the view of the components is largely blocked by other heat generating components at about the same temperature, and hot components face other hot surfaces instead of cooler surfaces.

15-80 The surface temperature of a sealed electronic box placed on top of a stand is not to exceed 65°C. It is to be determined if this box can be cooled by natural convection and radiation alone.

Assumptions **1** Steady operating conditions exist. **2** The local atmospheric pressure is 1 atm.

Analysis Using Table 15-1, the heat transfer coefficient and the natural convection heat transfer from side surfaces are determined to be



$$L = 0.2\text{ m}$$

$$A_{side} = (2)(0.5\text{ m} + 0.35\text{ m})(0.2\text{ m}) = 0.34\text{ m}^2$$

$$h_{conv,side} = 1.42\left(\frac{\Delta T}{L}\right)^{0.25} = 1.42\left(\frac{65-30}{0.2}\right)^{0.25} = 5.16\text{ W/m.°C}$$

$$\dot{Q}_{conv,side} = h_{conv,side}A_{side}(T_s - T_{fluid})$$
$$= (5.16\text{ W/m.°C})(0.34\text{ m}^2)(65-30)\text{°C} = 61.5\text{ W}$$

The heat transfer from the horizontal top surface by natural convection is

$$L = \frac{4A_{top}}{p} = \frac{4(0.5\text{ m})(0.35\text{ m})}{(2)(0.5\text{ m} + 0.35\text{ m})} = 0.41\text{ m}$$

$$A_{top} = (0.5\text{ m})(0.35\text{ m}) = 0.175\text{ m}^2$$

$$h_{conv,top} = 1.32\left(\frac{\Delta T}{L}\right)^{0.25} = 1.32\left(\frac{65-30}{0.41}\right)^{0.25} = 4.01\text{ W/m.°C}$$

$$\dot{Q}_{conv,top} = h_{conv,top}A_{top}(T_s - T_{fluid}) = (4.01\text{ W/m.°C})(0.175\text{ m}^2)(65-30)\text{°C} = 24.6\text{ W}$$

The rate of heat transfer from the box by radiation is determined from

$$\dot{Q}_{rad} = \varepsilon A_s \sigma (T_s^{\,4} - T_{surr}^{\,4})$$
$$= (0.85)(0.34\text{ m}^2 + 0.175\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2.\text{K}^4)[(65+273\text{ K})^4 - (30+273\text{ K})^4] = 114.7\text{ W}$$

Then the total rate of heat transfer from the box becomes

$$\dot{Q}_{total} = \dot{Q}_{conv,side} + \dot{Q}_{conv,top} + \dot{Q}_{rad} = 61.5 + 24.6 + 114.7 = \mathbf{200.8\ W}$$

which is greater than 100 W. Therefore, this box can be cooled by combined natural convection and radiation.

15-81 The surface temperature of a sealed electronic box placed on top of a stand is not to exceed 65°C. It is to be determined if this box can be cooled by natural convection and radiation alone.

Assumptions **1** Steady operating conditions exist. **2** The local atmospheric pressure is 1 atm.

Analysis In given orientation, two side surfaces and the top surface will be vertical and other two side surfaces will be horizontal. Using Table 15-1, the heat transfer coefficient and the natural convection heat transfer from the vertical surfaces are determined to be

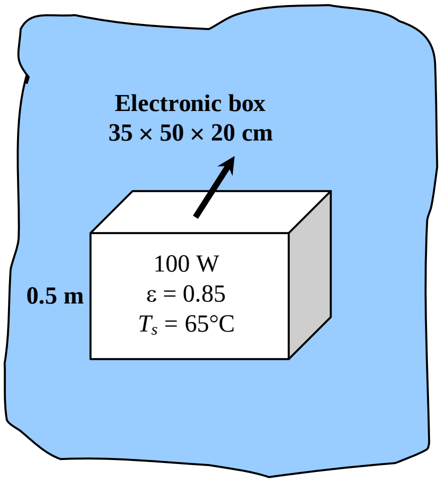
$$L = 0.5\text{ m}$$

$$A_{vertical} = (2\times 0.2\times 0.5 + 0.5\times 0.35) = 0.375\text{ m}^2$$

$$h_{\underset{vertical}{conv}} = 1.42\left(\frac{\Delta T}{L}\right)^{0.25} = 1.42\left(\frac{65-30}{0.5}\right)^{0.25} = 4.107\text{ W/m.°C}$$

$$\dot{Q}_{\underset{vertical}{conv}} = h_{\underset{vertical}{conv}} A_{vertical}(T_s - T_{fluid})$$

$$= (4.107\text{ W/m.°C})(0.375\text{ m}^2)(65-30)\text{°C} = 53.9\text{ W}$$



The heat transfer from the horizontal top surface by natural convection is

$$A_{top} = (0.2\text{ m})(0.35\text{ m}) = 0.07\text{ m}^2$$

$$L = \frac{4A_{top}}{p} = \frac{(4)(0.07\text{ m}^2)}{(4)(0.2\text{ m} + 0.35\text{ m})} = 0.1273\text{ m}$$

$$h_{\underset{top}{conv}} = 1.32\left(\frac{\Delta T}{L}\right)^{0.25} = 1.32\left(\frac{65-30}{0.1273}\right)^{0.25} = 5.4\text{ W/m.°C}$$

$$\dot{Q}_{\underset{top}{conv}} = h_{\underset{top}{conv}} A_{top}(T_s - T_{fluid})$$

$$= (5.4\text{ W/m.°C})(0.07\text{ m}^2)(65-30)\text{°C} = 13.2\text{ W}$$

The heat transfer from the horizontal top surface by natural convection is

$$h_{\underset{bottom}{conv}} = 0.59\left(\frac{\Delta T}{L}\right)^{0.25} = 0.59\left(\frac{65-30}{0.1273}\right)^{0.25} = 2.4\text{ W/m.°C}$$

$$\dot{Q}_{\underset{bottom}{conv}} = h_{\underset{bottom}{conv}} A_{bottom}(T_s - T_{fluid}) = (2.4\text{ W/m.°C})(0.07\text{ m}^2)(65-30)\text{°C} = 5.9\text{ W}$$

The rate of heat transfer from the box by radiation is determined from

$$\dot{Q}_{rad} = \varepsilon A_s \sigma (T_s{}^4 - T_{surr}{}^4)$$

$$= (0.85)(0.34\text{ m}^2 + 0.175\text{ m}^2)(5.67\times 10^{-8}\text{ W/m}^2.\text{K}^4)[(65+273\text{ K})^4 - (30+273\text{ K})^4] = 114.7\text{ W}$$

Then the total rate of heat transfer from the box becomes

$$\dot{Q}_{total} = \dot{Q}_{\underset{vertical}{conv}} + \dot{Q}_{\underset{top}{conv}} + \dot{Q}_{\underset{bottom}{conv}} + \dot{Q}_{rad} = 53.9 + 13.2 + 5.9 + 114.7 = \mathbf{187.7\text{ W}}$$

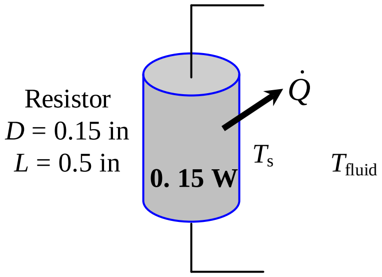
which is greater than 100 W. Therefore, this box can be cooled by combined natural convection and radiation.

15-82E A small cylindrical resistor mounted on a PCB is being cooled by natural convection and radiation. The surface temperature of the resistor is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The local atmospheric pressure is 1 atm. **3** Radiation is negligible in this case since the resistor is surrounded by surfaces which are at about the same temperature, and the radiation heat transfer between two surfaces at the same temperature is zero. This leaves natural convection as the only mechanism of heat transfer from the resistor.

Analysis For components on a circuit board, the heat transfer coefficient relation from Table 15-1 is

$$h_{conv} = 0.50\left(\frac{T_s - T_{fluid}}{D}\right)^{0.25} \qquad (L = D)$$



Substituting it into the heat transfer relation to get

$$\dot{Q}_{conv} = h_{conv} A_s (T_s - T_{fluid})$$
$$= 0.50\left(\frac{T_s - T_{fluid}}{D}\right)^{0.25} A_s (T_s - T_{fluid})$$
$$= 0.50 A_s \frac{(T_s - T_{fluid})^{1.25}}{D^{0.25}}$$

Calculating surface area and substituting it into above equation for the surface temperature yields

$$A_s = 2\left(\frac{\pi D^2}{4}\right) + \pi DL = 2\left[\frac{\pi (0.15/12\text{ ft})^2}{4}\right] + \pi (0.15/12\text{ ft})(0.5/12\text{ ft}) = 0.00188\text{ ft}^2$$

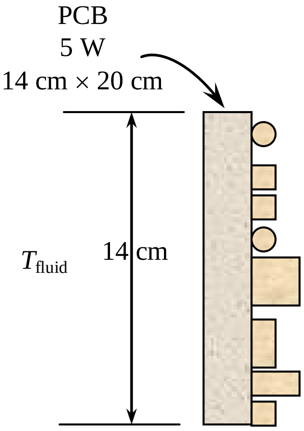
$$(0.15\text{ W} \times 3.41214\text{ Btu/h.W}) = (0.50)(0.00188\text{ ft}^2)\frac{(T_s - 130)^{1.25}}{(0.15/12\text{ ft})^{0.25}} \longrightarrow T_s = \mathbf{194°F}$$

15-83 The surface temperature of a PCB is not to exceed 90°C. The maximum environment temperatures for safe operation at sea level and at 3,000 m altitude are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Radiation heat transfer is negligible since the PCB is surrounded by other PCBs at about the same temperature. **3** Heat transfer from the back surface of the PCB will be very small and thus negligible.

Analysis Using the simplified relation for a vertical orientation from Table 15-1, the natural convection heat transfer coefficient is determined to be

$$h_{conv} = 1.42\left(\frac{T_s - T_{fluid}}{L}\right)^{0.25}$$



Substituting it into the heat transfer relation to get

$$\begin{aligned}\dot{Q}_{conv} &= h_{conv}A_s(T_s - T_{fluid})\\ &= 1.42\left(\frac{T_s - T_{fluid}}{L}\right)^{0.25} A_s(T_s - T_{fluid})\\ &= 1.42A_s\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}}\end{aligned}$$

Calculating surface area and characteristic length and substituting them into above equation for the surface temperature yields

$$L = 0.14\text{ m}$$

$$A_s = (0.14\text{ m})(0.2\text{ m}) = 0.028\text{ m}^2$$

$$5\text{ W} = (1.42)(0.028\text{ m}^2)\frac{(90 - T_{fluid})^{1.25}}{(0.14\text{ m})^{0.25}} \longrightarrow T_{fluid} = \mathbf{57.7°C}$$

At an altitude of 3000 m, the atmospheric pressure is 70.12 kPa which is equivalent to

$$P = (70.12\text{ kPa})\frac{1\text{ atm}}{101.325\text{ kPa}} = 0.692\text{ atm}$$

Modifying the heat transfer relation for this pressure (by multiplying by the square root of it) yields

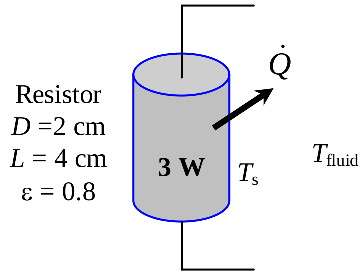
$$5\text{ W} = (1.42)(0.028\text{ m}^2)\frac{(90 - T_{fluid})^{1.25}}{(0.14\text{ m})^{0.25}}\sqrt{0.692} \longrightarrow T_{fluid} = \mathbf{52.6°C}$$

15-84 A cylindrical electronic component is mounted on a board with its axis in the vertical direction. The average surface temperature of the component is to be determined.

Assumptions **1** Steady operating conditions exist. **2** The local atmospheric pressure is 1 atm.

Analysis The natural convection heat transfer coefficient for vertical orientation using Table 15-1 can be determined from

$$h_{conv} = 1.42\left(\frac{T_s - T_{fluid}}{L}\right)^{0.25}$$



Substituting it into the heat transfer relation gives

$$\begin{aligned}\dot{Q}_{conv} &= h_{conv}A_s(T_s - T_{fluid})\\ &= 1.42\left(\frac{T_s - T_{fluid}}{L}\right)^{0.25} A_s(T_s - T_{fluid})\\ &= 1.42A_s\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}}\end{aligned}$$

The rate of heat transfer from the cylinder by radiation is

$$\dot{Q}_{rad} = \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$

Then the total rate of heat transfer can be written as

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad} = 1.42A_s\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}} + \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$

We will calculate total surface area of the cylindrical component including top and bottom surfaces, and assume the natural heat transfer coefficient to be the same throughout all surfaces of the component

$$A_s = 2\left(\frac{\pi D^2}{4}\right) + \pi DL = 2\left[\frac{\pi(0.02\text{ m})^2}{4}\right] + \pi(0.02\text{ m})(0.04\text{ m}) = 0.00314\text{ m}^2$$

Substituting

$$\begin{aligned}3\text{ W} = (1.42)(0.00314\text{ m}^2)&\frac{[T_s - (30+273\text{ K})]^{1.25}}{(0.04\text{ m})^{0.25}}\\ &+ (0.8)(0.00314\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\text{K}^4)[T_s{}^4 - (20+273\text{ K})^4]\end{aligned}$$

Solving for the surface temperature gives

$$T_s = 363\text{ K} = \mathbf{90°C}$$

15-85 A cylindrical electronic component is mounted on a board with its axis in horizontal direction. The average surface temperature of the component is to be determined.

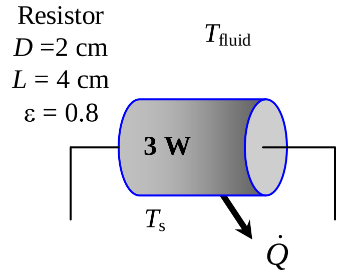
Assumptions **1** Steady operating conditions exist. **2** The local atmospheric pressure is 1 atm.

Analysis Since atmospheric pressure is not given, we assume it to be 1 atm. The natural convection heat transfer coefficient for horizontal orientation using Table 15-1 can be determined from

$$h_{conv} = 1.32\left(\frac{T_s - T_{fluid}}{D}\right)^{0.25}$$

Substituting it into the heat transfer relation to get

$$\begin{aligned}\dot{Q}_{conv} &= h_{conv}A_s(T_s - T_{fluid})\\ &= 1.32\left(\frac{T_s - T_{fluid}}{D}\right)^{0.25} A_s(T_s - T_{fluid})\\ &= 1.32A_s\frac{(T_s - T_{fluid})^{1.25}}{D^{0.25}}\end{aligned}$$



The rate of heat transfer from the cylinder by radiation is

$$\dot{Q}_{rad} = \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$

Then the total heat transfer can be written as

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad} = 1.32A_s\frac{(T_s - T_{fluid})^{1.25}}{D^{0.25}} + \varepsilon A\sigma(T_s{}^4 - T_{surr}{}^4)$$

We will calculate total surface area of the cylindrical component including top and bottom surfaces, and assume the natural heat transfer coefficient to be the same throughout all surfaces of the component

$$A_s = 2\left(\frac{\pi D^2}{4}\right) + \pi DL = 2\left[\frac{\pi(0.02\text{ m})^2}{4}\right] + \pi(0.02\text{ m})(0.04\text{ m}) = 0.00314\text{ m}^2$$

Substituting,

$$\begin{aligned}3\text{ W} = {}&(1.32)(0.00314\text{ m}^2)\frac{[T_s - (30+273)\text{ K}]^{1.25}}{(0.02\text{ m})^{0.25}}\\ &+ (0.8)(0.00314\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\text{K}^4)[T_s{}^4 - (20+273\text{ K})^4]\end{aligned}$$

Solving for the surface temperature gives

$$T_s = 361\text{ K} = \mathbf{88^\circ C}$$

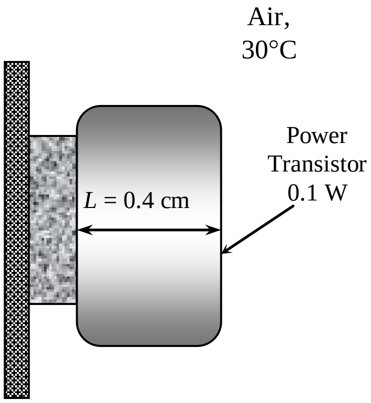
15-87 A power transistor dissipating 0.1 W of power is considered. The heat flux on the surface of the transistor and the surface temperature of the transistor are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat is transferred uniformly from all surfaces of the transistor.

Analysis (*a*) The heat flux on the surface of the transistor is



$$A_s = 2\left(\frac{\pi D^2}{4}\right) + \pi DL$$

$$= 2\left[\frac{\pi(0.4\text{ cm})^2}{4}\right] + \pi(0.4\text{ cm})(0.4\text{ cm}) = 0.754\text{ cm}^2$$

$$\dot{q} = \frac{\dot{Q}}{A_s} = \frac{0.1\text{ W}}{0.754\text{ cm}^2} = 0.1326\text{ W/cm}^2$$

(*b*) The surface temperature of the transistor is determined from Newton's law of cooling to be

$$\dot{q} = h_{combined}(T_s - T_{fluid})$$

$$T_s = T_{fluid} + \frac{\dot{q}}{h_{combined}} = 30°\text{C} + \frac{1326\text{ W/m}^2}{18\text{ W/m}^2.°\text{C}} = \mathbf{103.7°C}$$

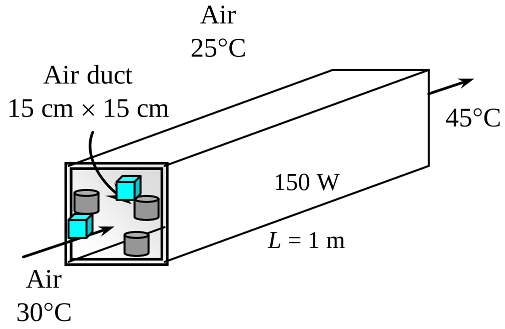
15-88 The components of an electronic equipment located in a horizontal duct with rectangular cross-section are cooled by forced air. The heat transfer from the outer surfaces of the duct by natural convection and the average temperature of the duct are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Radiation heat transfer from the outer surfaces is negligible.

Analysis (*a*) Using air properties at 300 K and 1 atm, the mass flow rate of air and the heat transfer rate by forced convection are determined to be

$$\dot{m} = \rho\dot{V} = (1.177\ \text{kg/m}^3)(0.4/60\ \text{m}^3/\text{s}) = 0.00785\ \text{kg/s}$$

$$\dot{Q}_{\substack{forced\\convection}} = \dot{m}C_p \Delta T = (0.00785\ \text{kg/s})(1005\ \text{J/kg.°C})(45-30)\text{°C} = 118.3\ \text{W}$$



Noting that radiation heat transfer is negligible, the rest of the 150 W heat generated must be dissipated by natural convection,

$$\dot{Q}_{\substack{natural\\convection}} = \dot{Q}_{total} - \dot{Q}_{\substack{forced\\convection}} = 150 - 118.3 = \mathbf{31.7\ W}$$

(*b*) The natural convection heat transfer from the vertical side surfaces of the duct is

$$A_{side} = 2\times(0.15\ \text{m})(1\ \text{m}) = 0.3\ \text{m}^2$$

$$h_{conv,side} = 1.42\left(\frac{\Delta T}{L}\right)^{0.25}$$

$$\dot{Q}_{conv,side} = h_{conv,side}A_{side}(T_s - T_{fluid}) = 1.42\left(\frac{(T_s - T_{fluid})}{L}\right)^{0.25} A_{side}(T_s - T_{fluid})$$

$$= 1.42 A_{side}\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}}$$

Natural convection from the top and bottom surfaces of the duct is

$$L = \frac{4A_{top}}{p} = \frac{(4)(0.15\ \text{m})(1\ \text{m})}{(2)(0.15\ \text{m} + 1\ \text{m})} = 0.26\ \text{m}, \quad A_{top} = (0.15\ \text{m})(1\ \text{m}) = 0.15\ \text{m}^2, \quad h_{conv,top} = 1.32\left(\frac{\Delta T}{L}\right)^{0.25}$$

$$\dot{Q}_{conv,top} = h_{conv,top}A_{top}(T_s - T_{fluid}) = 1.32\left(\frac{(T_s - T_{fluid})}{L}\right)^{0.25} A_{top}(T_s - T_{fluid}) = 1.32 A_{top}\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}}$$

$$h_{conv,bottom} = 0.59\left(\frac{\Delta T}{L}\right)^{0.25}$$

$$\dot{Q}_{conv,bottom} = h_{conv,bot}A_{top}(T_s - T_{fluid}) = 0.59\left(\frac{(T_s - T_{fluid})}{L}\right)^{0.25} A_{bot}(T_s - T_{fluid}) = 0.59 A_{bot}\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}}$$

Then the total heat transfer by natural convection becomes

$$\dot{Q}_{total,conv} = \dot{Q}_{conv,side} + \dot{Q}_{conv,top} + \dot{Q}_{conv,bottom}$$

$$\dot{Q}_{total,conv} = 1.42 A_{side}\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}} + 1.32 A_{top}\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}} + 0.59 A_{bottom}\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}}$$

Substituting all known quantities with proper units gives the average temperature of the duct to be

$$31.7 = (1.42)(0.3)\frac{(T_s - 25)^{1.25}}{0.15^{0.25}} + (1.32)(0.15)\frac{(T_s - 25)^{1.25}}{0.26^{0.25}} + (0.59)(0.15)\frac{(T_s - 25)^{1.25}}{0.26^{0.25}}$$

$$31.7 = (1.086)(T_s - 25)^{1.25} \longrightarrow T_s = \mathbf{40°C}$$

15-89 The components of an electronic equipment located in a circular horizontal duct are cooled by forced air. The heat transfer from the outer surfaces of the duct by natural convection and the average temperature of the duct are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Radiation heat transfer from the outer surfaces is negligible.

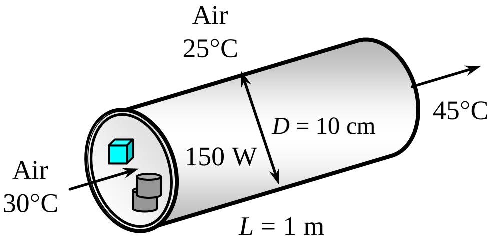
Analysis (*a*) Using air properties at 300 K and 1 atm, the mass flow rate of air and the heat transfer rate by forced convection are determined to be

$$\dot{m} = \rho\dot{V} = (1.177\text{ kg/m}^3)(0.4/60\text{ m}^3/\text{s}) = 0.00785\text{ kg/s}$$

$$\dot{Q}_{\substack{forced\\convection}} = \dot{m}C_p\Delta T = (0.00785\text{ kg/s})(1005\text{ J/kg.°C})(45-30)\text{°C} = 118.3\text{ W}$$

Noting that radiation heat transfer is negligible, the rest of the 150 W heat generated must be dissipated by natural convection,

$$\dot{Q}_{\substack{natural\\convection}} = \dot{Q}_{total} - \dot{Q}_{\substack{forced\\convection}} = 150 - 118.3 = \mathbf{31.7\text{ W}}$$



(*b*) The natural convection heat transfer from the circular duct is

$$L = D = 0.1\text{ m}$$

$$A_s = 2\left(\frac{\pi D^2}{4}\right) + \pi DL = 2\left[\frac{\pi(0.1\text{ m})^2}{4}\right] + \pi(0.1\text{ m})(1\text{ m}) = 0.33\text{ m}^2$$

$$h_{conv} = 1.32\left(\frac{\Delta T}{D}\right)^{0.25}$$

$$\dot{Q}_{conv} = h_{conv}A(T_s - T_{fluid}) = 1.32\left(\frac{(T_s - T_{fluid})}{D}\right)^{0.25} A_s(T_s - T_{fluid})$$

$$= 1.32A_s\frac{(T_s - T_{fluid})^{1.25}}{D^{0.25}}$$

Substituting all known quantities with proper units gives the average temperature of the duct to be

$$31.7\text{ W} = (1.32)(0.33\text{ m}^2)\frac{(T_s - 25)^{1.25}}{(0.1\text{ m})^{0.25}} \longrightarrow T_s = \mathbf{44°C}$$

15-91 The components of an electronic equipment located in a horizontal duct with rectangular cross-section are cooled by forced air. The heat transfer from the outer surfaces of the duct by natural convection and the average temperature of the duct are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Radiation heat transfer from the outer surfaces is negligible.

Analysis In this case the entire 150 W must be dissipated by natural convection from the outer surface of the duct. Natural convection from the vertical side surfaces of the duct can be expressed as

$$L = 0.15\text{ m} \qquad A_{side} = 2\times(0.15\text{ m})(1\text{ m}) = 0.3\text{ m}^2$$

$$h_{conv,side} = 1.42\left(\frac{\Delta T}{L}\right)^{0.25}$$

$$\dot{Q}_{conv,side} = h_{conv,side}A_{side}(T_s - T_{fluid}) = 1.42\left(\frac{(T_s - T_{fluid})}{L}\right)^{0.25}A_{side}(T_s - T_{fluid})$$

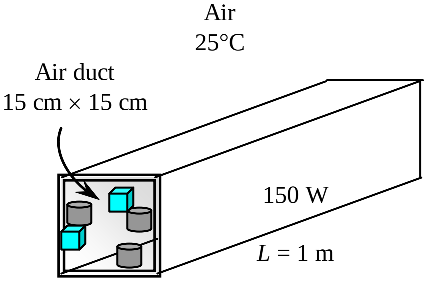
$$= 1.42A_{side}\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}}$$

Natural convection from the top surface of the duct is

$$L = \frac{4A_{top}}{p} = \frac{(4)(0.15\text{ m})(1\text{ m})}{(2)(0.15\text{ m}+1\text{ m})} = 0.26\text{ m}$$

$$A_{top} = (0.15\text{ m})(1\text{ m}) = 0.15\text{ m}^2$$

$$h_{conv,top} = 1.32\left(\frac{\Delta T}{L}\right)^{0.25}$$



$$\dot{Q}_{conv,top} = h_{conv,top}A_{top}(T_s - T_{fluid}) = 1.32\left(\frac{(T_s - T_{fluid})}{L}\right)^{0.25}A_{top}(T_s - T_{fluid})$$

$$= 1.32A_{top}\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}}$$

Natural convection from the bottom surface of the duct is

$$h_{conv,bottom} = 0.59\left(\frac{\Delta T}{L}\right)^{0.25}$$

$$\dot{Q}_{conv,bottom} = h_{conv,bottom}A_{top}(T_s - T_{fluid}) = 0.59\left(\frac{(T_s - T_{fluid})}{L}\right)^{0.25}A_{bottom}(T_s - T_{fluid})$$

$$= 0.59A_{bottom}\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}}$$

Then the total heat transfer by natural convection becomes

$$\dot{Q}_{total,conv} = \dot{Q}_{conv,side} + \dot{Q}_{conv,top} + \dot{Q}_{conv,bottom}$$

$$\dot{Q}_{total,conv} = 1.42A_{side}\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}} + 1.32A_{top}\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}} + 0.59A_{bottom}\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}}$$

Substituting all known quantities with proper units gives the average temperature of the duct to be

$$150 = (1.42)(0.3)\frac{(T_s - 25)^{1.25}}{0.15^{0.25}} + (1.32)(0.15)\frac{(T_s - 25)^{1.25}}{0.26^{0.25}} + (0.59)(0.15)\frac{(T_s - 25)^{1.25}}{0.26^{0.25}}$$

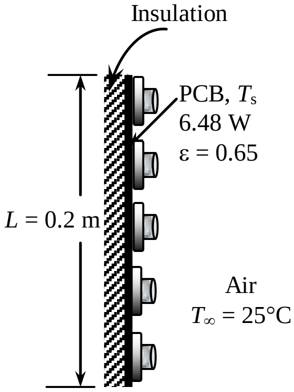
$$150 = (1.086)(T_s - 25)^{1.25} \longrightarrow T_s = \mathbf{77°C}$$

15-92 A wall-mounted circuit board containing 81 square chips is cooled by combined natural convection and radiation. The surface temperature of the chips is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Heat transfer from the back side of the circuit board is negligible. **3** Temperature of surrounding surfaces is the same as the air temperature. **3** The local atmospheric pressure is 1 atm.

Analysis The natural convection heat transfer coefficient for the vertical orientation of board can be determined from (Table 15-1)

$$h_{conv} = 1.42\left(\frac{T_s - T_{fluid}}{L}\right)^{0.25}$$



Substituting it relation into the heat transfer relation gives

$$\dot{Q}_{conv} = h_{conv}A_s(T_s - T_{fluid})$$
$$= 1.42\left(\frac{T_s - T_{fluid}}{L}\right)^{0.25} A(T_s - T_{fluid}) = 1.42A\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}}$$

The rate of heat transfer from the board by radiation is

$$\dot{Q}_{rad} = \varepsilon A_s \sigma\left(T_s^{\,4} - T_{surr}^{\,4}\right)$$

Then the total heat transfer can be expressed as

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad} = 1.42A_s\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}} + \varepsilon A_s \sigma(T_s^{\,4} - T_{surr}^{\,4})$$

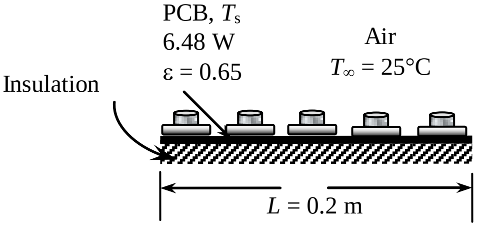
where $\dot{Q}_{total} = (0.08\text{ W})\times 81 = 6.48\text{ W}$. Noting that the characteristic length is L = 0.2 m, calculating the surface area and substituting the known quantities into the above equation, the surface temperature is determined to be

$$L = 0.2\text{ m}$$
$$A_s = (0.2\text{ m})(0.2\text{ m}) = 0.04\text{ m}^2$$
$$6.48\text{ W} = (2.44)(0.04\text{ m}^2)\frac{[T_s - (25+273\text{ K})]^{1.25}}{(0.2\text{ m})^{0.25}}$$
$$+ (0.65)(0.04\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\text{K}^4)\left[T_s^{\,4} - (25+273\text{ K})^4\right]$$
$$T_s = 312.3\text{ K} = \mathbf{39.3°C}$$

15-93 A horizontal circuit board containing 81 square chips is cooled by combined natural convection and radiation. The surface temperature of the chips is to be determined for two cases.

Assumptions **1** Steady operating conditions exist. **2** Heat transfer from the back side of the circuit board is negligible. **3** Temperature of surrounding surfaces is the same as the air temperature. **3** The local atmospheric pressure is 1 atm.

Analysis (*a*) The natural convection heat transfer coefficient for the horizontal orientation of board with chips facing up can be determined from (Table 15-1)



$$h_{conv} = 1.32\left(\frac{T_s - T_{fluid}}{L}\right)^{0.25}$$

Substituting it into the heat transfer relation gives

$$\dot{Q}_{conv} = h_{conv}A_s(T_s - T_{fluid})$$
$$= 1.32\left(\frac{T_s - T_{fluid}}{L}\right)^{0.25} A_s(T_s - T_{fluid}) = 1.32A_s\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}}$$

The rate of heat transfer from the board by radiation is

$$\dot{Q}_{rad} = \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$

Then the total heat transfer can be written as

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad} = 1.32A_s\frac{(T_s - T_{fluid})^{1.25}}{L^{0.25}} + \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)$$

where $\dot{Q}_{total} = (0.08\text{ W})\times 81 = 6.48\text{ W}$. Noting that the characteristic length is L = 0.2 m, calculating the surface area and substituting the known quantities into the above equation, the surface temperature is determined to be

$$L = \frac{4A_s}{p} = \frac{(4)(0.2\text{ m})(0.2\text{ m})}{(4)(0.2\text{ m})} = 0.2\text{ m} \qquad A_s = (0.2\text{ m})(0.2\text{ m}) = 0.04\text{ m}^2$$

$$6.48\text{ W} = (1.32)(0.04\text{ m}^2)\frac{(T_s - (25+273)\text{K})^{1.25}}{(0.2\text{ m})^{0.25}}$$
$$+ (0.65)(0.04\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\text{K}^4)[T_s{}^4 - (25+273\text{ K})^4]$$
$$T_s = 317.2\text{ K} = \mathbf{44.2°C}$$

(*b*) The solution in this case (the chips are facing down instead of up) is identical to the one above, except we must replace the constant 1.32 in the heat transfer coefficient relation by 0.59. Then the surface temperature in this case becomes

$$6.48\text{ W} = (0.59)(0.04\text{ m}^2)\frac{(T_s - (25+273)\text{K})^{1.25}}{(0.2\text{ m})^{0.25}}$$
$$+ (0.65)(0.04\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\text{K}^4)[T_s{}^4 - (25+273\text{ K})^4]$$
$$T_s = 323.3\text{ K} = \mathbf{50.3°C}$$

Air Cooling: Forced Convection

15-94C Radiation heat transfer in forced air cooled systems is usually disregarded with no significant error since the forced convection heat transfer coefficient is usually much larger than the radiation heat transfer coefficient.

15-95C We would definitely prefer natural convection cooling whenever it is adequate in order to avoid all the problems associated with the fans such as cost, power consumption, noise, complexity, maintenance, and possible failure.

15-96C The convection heat transfer coefficient depends strongly on the average fluid velocity. Forced convection usually involves much higher fluid velocities, and thus much higher heat transfer coefficients. Consequently, forced convection cooling is much more effective.

15-97C Increasing the flow rate of air will increase the heat transfer coefficient. Then from Newton's law of cooling $\dot{Q}_{conv} = hA_s(T_s - T_{fluid})$, it becomes obvious that for a fixed amount of power, the temperature difference between the surface and the air will decrease. Therefore, the surface temperature will decrease. The exit temperature of the air will also decrease since $\dot{Q}_{conv} = \dot{m}_{air}C_p(T_{out} - T_{in})$ and the flow rate of air is increased.

15-98C Fluid flow over a body is called external flow, and flow through a confined space such as a tube or the parallel passage area between two circuit boards in an enclosure is called internal flow. A fan cooled personal computer left in windy area involves both types of flow.

15-99C For a specified power dissipation and air inlet temperature, increasing the heat transfer coefficient will decrease the surface temperature of the electronic components since, from Newton's law of cooling, $\dot{Q}_{conv} = hA_s(T_s - T_{fluid})$

15-100C A fan at a fixed speed (or fixed rpm) will deliver a fixed volume of air regardless of the altitude and pressure. But the mass flow rate of air will be less at high altitude as a result of the lower density of air. This may create serious reliability problems and catastrophic failures of electronic equipment if proper precautions are not taken. Variable speed fans which automatically increase the speed when the air density decreases are available to avoid such problems.

15-101C A fan placed at the inlet draws the air in and pressurizes the electronic box, and prevents air infiltration into the box through the cracks or other openings. Having only one location for air inlet makes it practical to install a filter at the inlet to catch all the dust and dirt before they enter the box. This allows the electronic system to operate in a clean environment. Also, the fan placed at the inlet handles cooler and thus denser air which results in a higher mass flow rate for the same volume flow rate or rpm. Being subjected to cool air has the added benefit that it increases the reliability and extends the life of the fan. The major disadvantage associated with the fan mounted at the inlet is that the heat generated by the fan and its motor is picked up by air on its way into the box, which adds to the heat load of the system.

When the fan is placed at the exit, the heat generated by the fan and its motor is immediately discarded to the atmosphere without getting blown first into the electronic box. However, the fan at the exit creates a vacuum inside the box, which draws air into the box through inlet vents as well as any cracks and openings. Therefore, the air is difficult to filter, and the dirt and dust which collects on the components undermine the reliability of the system.

15-102C The volume flow rate of air in a forced-air-cooled electronic system that has a constant speed fan is established at point where the fan static head curve and the system resistance curve intersects. Therefore, a fan will deliver a higher flow rate through a system which offers a lower flow resistance. A few PCBs added into an electronic box will increase the flow resistance and thus decrease the flow rate of air.

15-103C An undersized fan may cause the electronic system to overheat and fail. An oversized fan will definitely provide adequate cooling but it will needlessly be larger, noisier, more expensive, and will consume more power.

15-104 A hollow core PCB is cooled by forced air. The outlet temperature of the air and the highest surface temperature are to be determined.

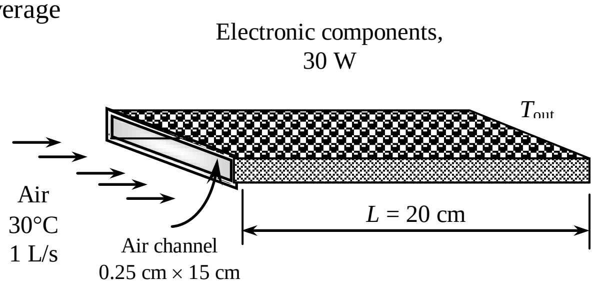
Assumptions **1** Steady operating conditions exist. **2** The inner surfaces of the duct are smooth. **3** Air is an ideal gas. **4** The local atmospheric pressure is 1 atm. **5** The entire heat generated in electronic components is removed by the air flowing through the hollow core.

Properties The air properties at the anticipated average temperature of 40°C and 1 atm (Table A-15) are

$$\rho = 1.127\ \text{kg/m}^3 \qquad C_p = 1007\ \text{J/kg.°C}$$

$$\text{Pr} = 0.7255 \qquad k = 0.02662\ \text{W/m.°C}$$

$$\nu = 1.702\times10^{-5}\ \text{m}^2/\text{s}$$



Analysis (*a*) The cross-sectional area of the channel and its hydraulic diameter are

$$A_c = (height)(width) = (0.15\ \text{m})(0.0025\ \text{m}) = 3.75\times10^{-4}\ \text{m}^2$$

$$D_h = \frac{4A_c}{p} = \frac{(4)(3.75\times10^{-4}\ \text{m}^2)}{(2)(0.15\ \text{m}+0.0025\ \text{m})} = 0.00492\ \text{m}$$

The average velocity and the mass flow rate of air are

$$\mathbf{V} = \frac{\dot{V}}{A_c} = \frac{1\times10^{-3}\ \text{m}^3/\text{s}}{3.75\times10^{-4}\ \text{m}^2} = 2.67\ \text{m/s}$$

$$\dot{m} = \rho\dot{V} = (1.127\ \text{kg/m}^3)(1\times10^{-3}\ \text{m}^3/\text{s}) = 1.127\times10^{-3}\ \text{kg/s}$$

Then the temperature of air at the exit of the hollow core becomes

$$\dot{Q} = \dot{m}C_p(T_{out} - T_{in})$$

$$T_{out} = T_{in} + \frac{\dot{Q}}{\dot{m}C_p} = 30°\text{C} + \frac{30\ \text{W}}{(1.127\times10^{-3}\ \text{kg/s})(1007\ \text{J/kg.°C})} = \mathbf{56.4°C}$$

(*b*) The highest surface temperature in the channel will occur near the exit, and the surface temperature there can be determined from

$$\dot{q}_{conv} = h(T_s - T_{fluid})$$

To determine heat transfer coefficient, we first need to calculate the Reynolds number,

$$\text{Re} = \frac{\mathbf{V}D_h}{\nu} = \frac{(2.67\ \text{m/s})(0.00492\ \text{m})}{1.702\times10^{-5}\ \text{m}^2/\text{s}} = 771.8 < 2300$$

Therefore the flow is laminar. Assuming fully developed flow, the Nusselt number for the air flow in this rectangular cross-section corresponding to the aspect ratio of $a/b = height/width = 15/0.25 = 60 \approx \infty$ is determined from Table 15-3 to be $Nu = 8.24$. Then,

$$h = \frac{k}{D_h}Nu = \frac{0.02662\ \text{W/m.°C}}{0.00492\ \text{m}}(8.24) = 44.58\ \text{W/m}^2.°\text{C}$$

The surface temperature of the hollow core near the exit is determined to be

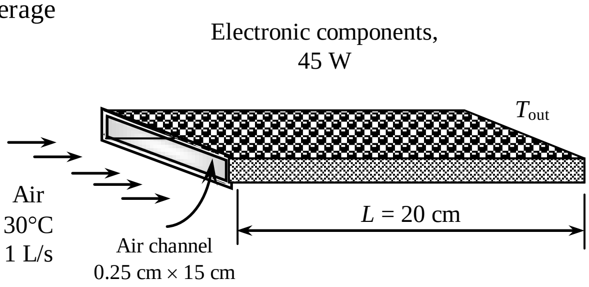
$$T_{s,\max} = T_{out} + \frac{\dot{q}}{h} = 56.4°\text{C} + \frac{(30\ \text{W})/(0.06\ \text{m}^2)}{(44.58\ \text{W/m}^2.°\text{C})} = \mathbf{67.6°C}$$

15-105 A hollow core PCB is cooled by forced air. The outlet temperature of the air and the highest surface temperature are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The inner surfaces of the duct are smooth. **3** Air is an ideal gas. **4** The local atmospheric pressure is 1 atm. **5** The entire heat generated in electronic components is removed by the air flowing through the hollow core.

Properties The air properties at the anticipated average temperature of 40°C and 1 atm (Table A-15) are

$$\rho = 1.127 \text{ kg/m}^3 \qquad C_p = 1007 \text{ J/kg.°C}$$
$$\text{Pr} = 0.7255 \qquad k = 0.02662 \text{ W/m.°C}$$
$$\nu = 1.702\times10^{-5} \text{ m}^2/\text{s}$$



Analysis (*a*) The cross-sectional area of the channel and its hydraulic diameter are

$$A_c = (height)(width) = (0.15 \text{ m})(0.0025 \text{ m}) = 3.75\times10^{-4} \text{ m}^2$$
$$D_h = \frac{4A_c}{p} = \frac{(4)(3.75\times10^{-4} \text{ m}^2)}{(2)(0.15 \text{ m}+0.0025 \text{ m})} = 0.00492 \text{ m}$$

The average velocity and the mass flow rate of air are

$$\mathbf{V} = \frac{\dot V}{A_c} = \frac{1\times10^{-3} \text{ m}^3/\text{s}}{3.75\times10^{-4} \text{ m}^2} = 2.67 \text{ m/s}$$
$$\dot m = \rho\dot V = (1.127 \text{ kg/m}^3)(1\times10^{-3} \text{ m}^3/\text{s}) = 1.127\times10^{-3} \text{ kg/s}$$

Then the temperature of air at the exit of the hollow core becomes

$$\dot Q = \dot m C_p (T_{out} - T_{in})$$
$$T_{out} = T_{in} + \frac{\dot Q}{\dot m C_p} = 30°\text{C} + \frac{45 \text{ W}}{(1.127\times10^{-3} \text{ kg/s})(1007 \text{ J/kg.°C})} = \mathbf{69.7°C}$$

(*b*) The highest surface temperature in the channel will occur near the exit, and the surface temperature there can be determined from

$$\dot q_{conv} = h(T_s - T_{fluid})$$

To determine heat transfer coefficient, we first need to calculate the Reynolds number,

$$\text{Re} = \frac{\mathbf{V}D_h}{\nu} = \frac{(2.67 \text{ m/s})(0.00492 \text{ m})}{1.702\times10^{-5} \text{ m}^2/\text{s}} = 771.8 < 2300$$

Therefore the flow is laminar. Assuming fully developed flow, the Nusselt number for the air flow in this rectangular cross-section corresponding to the aspect ratio of $a/b = height/width = 15/0.25 = 60 \approx \infty$ is determined from Table 15-3 to be $Nu = 8.24$. Then,

$$h = \frac{k}{D_h} Nu = \frac{0.02662 \text{ W/m.°C}}{0.00492 \text{ m}}(8.24) = 44.58 \text{ W/m}^2\text{.°C}$$

The surface temperature of the hollow core near the exit is determined to be

$$T_{s,\max} = T_{out} + \frac{\dot q}{h} = 69.7°\text{C} + \frac{(45 \text{ W})/(0.06 \text{ m}^2)}{(44.58 \text{ W/m}^2\text{.°C})} = \mathbf{86.5°C}$$

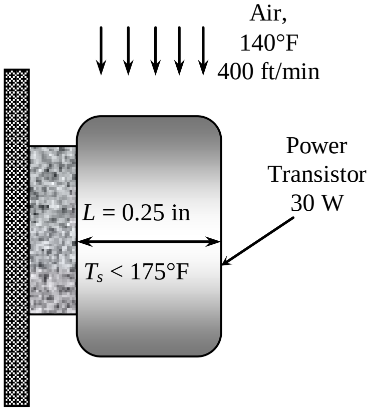
15-107E A transistor mounted on a circuit board is cooled by air flowing over it. The power dissipated when its case temperature is 175°F is to be determined.



Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at 1 atm pressure and the film temperature of $T_f = (T_s+T_{\text{fluid}})/2 = (175+140)/2 = 157.5$°F are (Table A-15E)

$$k = 0.0166 \text{ Btu/h.ft.°F}$$
$$\nu = 0.214\times10^{-3} \text{ ft}^2/\text{s}$$
$$\text{Pr} = 0.718$$

Analysis The transistor is cooled by forced convection through its cylindrical surface as well as its flat top surface. The characteristic length for flow over a cylinder is the diameter D=0.2 in. Then,

$$\text{Re} = \frac{\mathbf{V}D}{\nu} = \frac{(400/60 \text{ ft/s})(0.2/12 \text{ ft})}{0.214\times10^{-3} \text{ ft}^2/\text{s}} = 519$$

which falls into the range of 40-4000. Using the appropriate relation from Table 15-2, the Nusselt number and the convection heat transfer coefficient are determined to be

$$Nu = 0.683\,\text{Re}^{0.466}\,\text{Pr}^{1/3} = (0.683)(519)^{0.466}(0.718)^{1/3} = 11.3$$

$$h = \frac{k}{D}Nu = \frac{0.0166 \text{ Btu/h.ft.°F}}{(0.2/12 \text{ ft})}(11.3) = 11.2 \text{ Btu/h.ft}^2\text{.°F}$$

The transistor loses heat through its cylindrical surface as well as its circular top surface. For convenience, we take the heat transfer coefficient at the top surfaces to be the same as that of the side surface. (The alternative is to treat the top surface as a flat plate, but this will double the amount of calculations without providing much improvement in accuracy since the area of the top surface is much smaller and it is circular in shape rather than being rectangular). Then,

$$A_{cyl} = \pi DL + \pi D^2/4 = \pi(0.2/12 \text{ ft})(0.25/12 \text{ ft}) + \pi(0.2/12 \text{ ft})^2/4 = 0.00131 \text{ ft}^2$$

$$\dot{Q}_{cyl} = hA_{cyl}(T_s - T_{fluid}) = (11.2 \text{ Btu/h.ft}^2\text{.°F})(0.00131 \text{ ft}^2)(175-140)\text{°F} = 0.514 \text{ Btu/h} = \mathbf{0.15\ W}$$

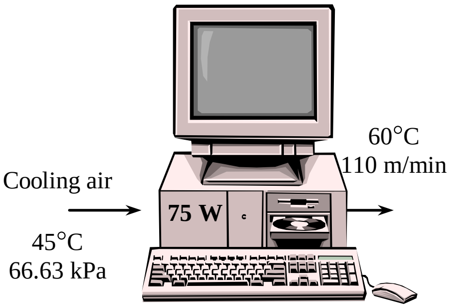
since 1 W = 3.4121 Btu/h. Therefore, the transistor can dissipate 0.15 W safely.

15-108 A desktop computer is to be cooled by a fan safely in hot environments and high elevations. The air flow rate of the fan and the diameter of the casing are to be determined.

Assumptions **1** Steady operation under worst conditions is considered. **2** Air is an ideal gas.

Properties The specific heat of air at the average temperature of T_{ave} = (45+60)/2 = 52.5°C is C_p = 1007 J/kg.°C (Table A-15)

Analysis The fan selected must be able to meet the cooling requirements of the computer at worst conditions. Therefore, we assume air to enter the computer at 66.63 kPa and 45°C, and leave at 60°C. Then the required mass flow rate of air to absorb heat generated is determined to be



$$\dot{Q} = \dot{m}C_p(T_{out} - T_{in}) \rightarrow \dot{m} = \frac{\dot{Q}}{C_p(T_{out} - T_{in})} = \frac{75\text{ W}}{(1007\text{ J/kg.°C})(60 - 45)\text{°C}} = 0.00497\text{ kg/s} = 0.298\text{ kg/min}$$

The density of air entering the fan at the exit and its volume flow rate are

$$\rho = \frac{P}{RT} = \frac{66.63\text{ kPa}}{(0.287\text{ kPa.m}^3\text{/kg.K})(60 + 273)\text{K}} = 0.6972\text{ kg/m}^3$$

$$\dot{V} = \frac{\dot{m}}{\rho} = \frac{0.298\text{ kg/min}}{0.6972\text{ kg/m}^3} = \mathbf{0.427\ m^3/min}$$

For an average exit velocity of 110 m/min, the diameter of the casing of the fan is determined from

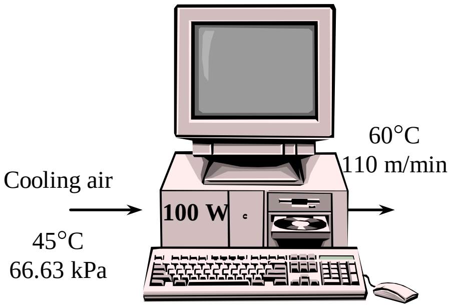
$$\dot{V} = A_c\mathbf{V} = \frac{\pi D^2}{4}\mathbf{V} \longrightarrow D = \sqrt{\frac{4\dot{V}}{\pi \mathbf{V}}} = \sqrt{\frac{(4)(0.427\text{ m}^3\text{/min})}{\pi(110\text{ m/min})}} = 0.070\text{ m} = \mathbf{7.0\ cm}$$

15-109 A desktop computer is to be cooled by a fan safely in hot environments and high elevations. The air flow rate of the fan and the diameter of the casing are to be determined.

Assumptions **1** Steady operation under worst conditions is considered. **2** Air is an ideal gas.

Properties The specific heat of air at the average temperature of T_{ave} = (45+60)/2 = 52.5°C is C_p = 1007 J/kg.°C (Table A-15)

Analysis The fan selected must be able to meet the cooling requirements of the computer at worst conditions. Therefore, we assume air to enter the computer at 66.63 kPa and 45°C, and leave at 60°C. Then the required mass flow rate of air to absorb heat generated is determined to be



$$\dot{Q} = \dot{m}C_p(T_{out} - T_{in}) \rightarrow \dot{m} = \frac{\dot{Q}}{C_p(T_{out} - T_{in})} = \frac{100\text{ W}}{(1007\text{ J/kg.°C})(60 - 45)\text{°C}} = 0.00662\text{ kg/s} = 0.397\text{ kg/min}$$

The density of air entering the fan at the exit and its volume flow rate are

$$\rho = \frac{P}{RT} = \frac{66.63\text{ kPa}}{(0.287\text{ kPa.m}^3\text{/kg.K})(60 + 273)\text{K}} = 0.6972\text{ kg/m}^3$$

$$\dot{V} = \frac{\dot{m}}{\rho} = \frac{0.397\text{ kg/min}}{0.6972\text{ kg/m}^3} = \mathbf{0.570\ m^3/min}$$

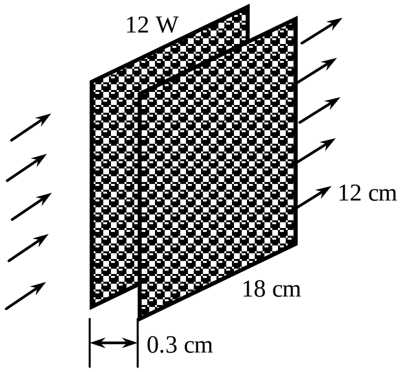
For an average exit velocity of 110 m/min, the diameter of the casing of the fan is determined from

$$\dot{V} = A_c\mathbf{V} = \frac{\pi D^2}{4}\mathbf{V} \longrightarrow D = \sqrt{\frac{4\dot{V}}{\pi \mathbf{V}}} = \sqrt{\frac{(4)(0.570\text{ m}^3\text{/min})}{\pi(110\text{ m/min})}} = 0.081\text{m} = \mathbf{8.1cm}$$

15-110 A computer is cooled by a fan, and the temperature rise of air is limited to 15°C. The flow rate of air, the fraction of the temperature rise of air caused by the fan and its motor, and maximum allowable air inlet temperature are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas. **3** The local atmospheric pressure is 1 atm. **4** The entire heat generated in electronic components is removed by the air flowing through the opening between the PCBs. **5** The entire power consumed by the fan motor is transferred as heat to the cooling air.

Properties We use air properties at 1 atm and 30°C since air enters at room temperature, and the temperature rise is limited to 15°C (Table A-15)



$$\rho = 1.164 \text{ kg/m}^3$$
$$C_p = 1007 \text{ J/kg.°C}$$
$$\Pr = 0.728$$
$$k = 0.0259 \text{ W/m.°C}$$
$$\nu = 1.61\times10^{-5} \text{ m}^2\text{/s}$$

Analysis (*a*) Because of symmetry, we consider the flow area between the two adjacent PCBs only. We assume the flow rate of air through all 8 channels to be identical, and to be equal to one-eighth of the total flow rate. The total mass and volume flow rates of air through the computer are determined from

$$\dot{Q} = \dot{m}C_p(T_{out} - T_{in}) \longrightarrow \dot{m} = \frac{\dot{Q}}{C_p(T_{out} - T_{in})} = \frac{[(8\times12)+15] \text{ J/s}}{(1007 \text{ J/kg.°C})(15\text{°C})} = 0.00735 \text{ kg/s}$$

$$\dot{V} = \frac{\dot{m}}{\rho} = \frac{0.00735 \text{ kg/s}}{1.164 \text{ kg/m}^3} = \mathbf{0.00631 \text{ m}^3\text{/s}}$$

Noting that we have 8 PCBs and the flow area between the PCBs is 0.12 m and 0.003 m wide, the air velocity is determined to be

$$\mathbf{V} = \frac{\dot{V}}{A_c} = \frac{(0.006819 \text{ m}^3\text{/s})/8}{(0.12 \text{ m})(0.003 \text{ m})} = 2.37 \text{ m/s}$$

(*b*) The temperature rise of air due to the 15 W of power consumed by the fan is

$$\Delta T_{air} = \frac{\dot{Q}_{fan}}{\dot{m}C_p} = \frac{15 \text{ W}}{(0.00735 \text{ kg/s})(1007 \text{ J/kg.°C})} = 2.0\text{°C}$$

Then the fraction of temperature rise of air which is due to the heat generated by the fan becomes

$$f = \frac{2.0\text{°C}}{15\text{°C}}\times100 = \mathbf{13.5\%}$$

(*c*) To determine the surface temperature, we need to evaluate the convection heat transfer coefficient,

$$A_c = (height)(width) = (0.12 \text{ m})(0.003 \text{ m}) = 0.00036 \text{ m}^2$$

$$D_h = \frac{4A_c}{p} = \frac{(4)(0.00036 \text{ m}^2)}{(2)(0.12 \text{ m} + 0.003 \text{ m})} = 0.00585 \text{ m}$$

$$\text{Re} = \frac{\mathbf{V}D_h}{\nu} = \frac{(2.37 \text{ m/s})(0.00585 \text{ m})}{1.61\times10^{-5} \text{ m}^2\text{/s}} = 861 < 2300$$

Therefore, the flow is laminar. (Actually, the components will cause the flow to be turbulent. The laminar assumption gives conservative results). Assuming fully developed flow, the Nusselt number for the air flow through this rectangular channel corresponding to the aspect ratio $a/b = 12/0.3 = 40 \approx \infty$ is determined from Table 15-3 to be $Nu = 8.24$. Then the heat transfer coefficient becomes

$$h = \frac{k}{D_h} Nu = \frac{0.0259 \text{ W/m.°C}}{0.00585 \text{ m}}(8.24) = 36.5 \text{ W/m}^2\text{.°C}$$

Disregarding the entrance effects, the temperature difference between the surface of the PCB and the air anywhere along the channel is determined to be

$$T_s - T_{fluid} = \frac{\dot{Q}}{hA_s} = \frac{12 \text{ W}}{(36.5 \text{ W/m}^2\text{.°C})(0.12 \times 0.18 \text{ m}^2)} = 15.2\text{°C}$$

The highest air and component temperatures will occur at the exit. Therefore, in the limiting case, the component surface temperature at the exit will be 90°C. The air temperature at the exit in this case will be

$$T_{out,\max} = T_{s,\max} - \Delta T_{rise} = 90\text{°C} - 15.2\text{°C} = 74.8\text{°C}$$

Noting that the air experiences a temperature rise of 15°C between the inlet and the exit, the inlet temperature of air becomes

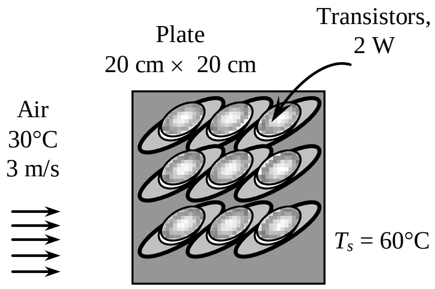
$$T_{in,\max} = T_{out,\max} - 15\text{°C} = 74.8\text{°C} - 15\text{°C} = \mathbf{59.8°C}$$

15-111 An array of power transistors is to be cooled by mounting them on a square aluminum plate and blowing air over the plate. The number of transistors that can be placed on this plate is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas. **3** The local atmospheric pressure is 1 atm. **4** The entire heat generated by transistors is removed by the air flowing over the plate. **5** The heat transfer from the back side of the plate is negligible.

Properties The properties of air at the free stream temperature of 30°C are (Table A-15)

$$\rho = 1.164 \text{ kg/m}^3$$
$$C_p = 1007 \text{ J/kg.°C}$$
$$\text{Pr} = 0.728$$
$$k = 0.0259 \text{ W/m.°C}$$
$$\nu = 1.61 \times 10^{-5} \text{ m}^2/\text{s}$$



Analysis The plate area and the convection heat transfer coefficient are determined to be (from Table 15-2)

$$A_s = (0.2 \text{ m})(0.2 \text{ m}) = 0.04 \text{ m}^2$$

$$\text{Re} = \frac{\mathbf{V}L}{\nu} = \frac{(3 \text{ m/s})(0.2 \text{ m})}{1.61 \times 10^{-5} \text{ m}^2\text{/s}} = 37{,}267$$

$$Nu = 0.664 \text{Re}^{1/2} \text{Pr}^{1/3} = (0.664)(37{,}267)^{1/2}(0.728)^{1/3} = 115.3$$

$$h = \frac{k}{L} Nu = \frac{0.0259 \text{ W/m.°C}}{0.2 \text{ m}}(115.3) = 14.9 \text{ W/m}^2\text{.°C}$$

The rate of heat transfer from the plate is

$$\dot{Q}_{conv} = hA_s(T_s - T_{fluid}) = (14.9 \text{ W/m}^2\text{.°C})(0.04 \text{ m}^2)(60 - 30)\text{°C} = 17.9 \text{ W}$$

Then the number of transistors that can be placed on this plate becomes

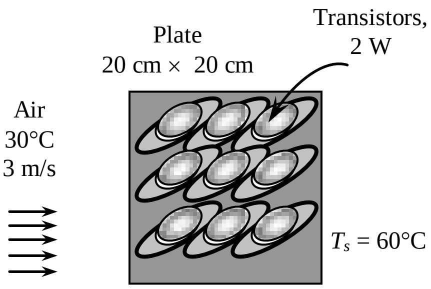
$$n = \frac{17.9 \text{ W}}{2 \text{ W}} = \mathbf{9} \text{ transistors}$$

15-112 An array of power transistors is to be cooled by mounting them on a square aluminum plate and blowing air over the plate. The number of transistors that can be placed on this plate is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas. **3** The local atmospheric pressure is 83.4 kPa. **4** The entire heat generated by transistors is removed by the air flowing over the plate. **5** The heat transfer from the back side of the plate is negligible.

Properties At an elevation of 1610 m, the atmospheric pressure is 83.4 kPa or

$$P = (83.4 \text{ kPa})\frac{1 \text{ atm}}{101.325 \text{ kPa}} = 0.823 \text{ atm}$$



The properties of air at 30°C are (Table A-15)

$$\rho = 1.164 \text{ kg/m}^3$$
$$C_p = 1007 \text{ J/kg.°C}$$
$$\text{Pr} = 0.728$$
$$k = 0.0259 \text{ W/m.°C}$$
$$\nu = 1.61\times10^{-5} \text{ m}^2/\text{s}/0.823 = 1.96\times10^{-5} \text{ m}^2/\text{s}$$

Analysis The plate area and the convection heat transfer coefficient are determined to be (from Table 15-2)

$$A_s = (0.2 \text{ m})(0.2 \text{ m}) = 0.04 \text{ m}^2$$

$$\text{Re} = \frac{\mathbf{V}L}{\nu} = \frac{(3 \text{ m/s})(0.2 \text{ m})}{1.96\times10^{-5} \text{ m}^2/\text{s}} = 30{,}612$$

$$Nu = 0.664\,\text{Re}^{1/2}\,\text{Pr}^{1/3} = (0.664)(30{,}612)^{1/2}(0.728)^{1/3} = 104.5$$

$$h = \frac{k}{L}Nu = \frac{0.0259 \text{ W/m.°C}}{0.2 \text{ m}}(104.5) = 13.5 \text{ W/m}^2\text{.°C}$$

The rate of heat transfer from the plate is

$$\dot{Q}_{conv} = hA_s(T_s - T_{fluid}) = (13.5 \text{ W/m}^2\text{.°C})(0.04 \text{ m}^2)(60-30)\text{°C} = 16.2 \text{ W}$$

Then the number of transistors that can be placed on this plate becomes

$$n = \frac{16.2 \text{ W}}{2 \text{ W}} = \mathbf{8} \text{ transistors}$$

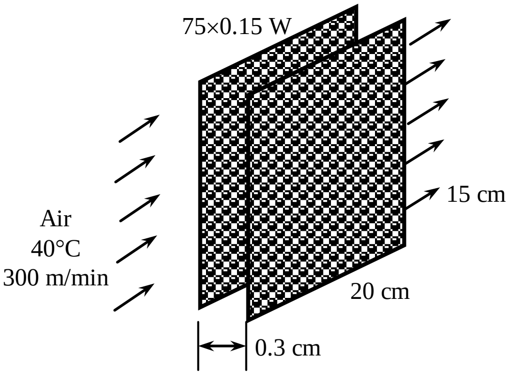
15-114 An enclosure containing an array of circuit boards is cooled by forced air flowing through the clearance between the tips of the components on the PCB and the back surface of the adjacent PCB. The exit temperature of the air and the highest surface temperature of the chips are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas. **3** The local atmospheric pressure is 1 atm. **4** The entire heat generated by the PCBs is removed by the air flowing through the clearance inside the enclosure. **5** The heat transfer from the back side of the circuit board is negligible.

Properties We use the properties of air at 1 atm and 40°C (Table A-15)

$$\rho = 1.127\ \text{kg/m}^3$$
$$C_p = 1007\ \text{J/kg.°C}$$
$$\text{Pr} = 0.726$$
$$k = 0.0266\ \text{W/m.°C}$$
$$\nu = 1.7 \times 10^{-5}\ \text{m}^2/\text{s}$$



Analysis The volume and the mass flow rates of air are

$$\dot{Q} = \dot{m}C_p\Delta T$$

$$\dot{m} = \frac{\dot{Q}}{C_p\Delta T} = \frac{3\ \text{kJ/s}}{(4.18\ \text{kJ/kg.°C})(4\text{°C})} = \mathbf{0.1794\ kg/s}$$

Then the exit temperature of air is determined from

$$\dot{Q} = \dot{m}C_p(T_{out} - T_{in}) \longrightarrow T_{out} = T_{in} + \frac{\dot{Q}}{\dot{m}C_p} = 40\text{°C} + \frac{(75\times 0.15)\text{W}}{(0.00255\ \text{kg/s})(1007\ \text{J/kg.°C})} = \mathbf{44.4°C}$$

To determine the surface temperature, we need to calculate the convection heat transfer coefficient first,

$$A_s = (0.15\ \text{m})(0.2\ \text{m}) = 0.03\ \text{m}^2$$

$$A_c = (0.15\ \text{m})(0.003\ \text{m}) = 0.00045\ \text{m}^2$$

$$D_h = \frac{4A_c}{p} = \frac{(4)(0.00045\ \text{m}^2)}{(2)(0.15\ \text{m} + 0.003\ \text{m})} = 0.0059\ \text{m}$$

$$\text{Re} = \frac{\mathbf{V}D_h}{\nu} = \frac{(300/60\ \text{m/s})(0.0059\ \text{m})}{1.7\times 10^{-5}\ \text{m}^2/\text{s}} = 1735 < 2300$$

Therefore, the flow is laminar. Assuming fully developed flow, the Nusselt number for the air flow in this rectangular cross-section corresponding to the aspect ratio of $a/b = height/width = 15/0.3 = 50 \approx \infty$ is determined from Table 15-3 to be $Nu = 8.24$. Then,

$$h = \frac{k}{L}Nu = \frac{0.0266\ \text{W/m.°C}}{0.0059\ \text{m}}(8.24) = 37.1\ \text{W/m}^2.\text{°C}$$

The highest surface temperature of the chips then becomes

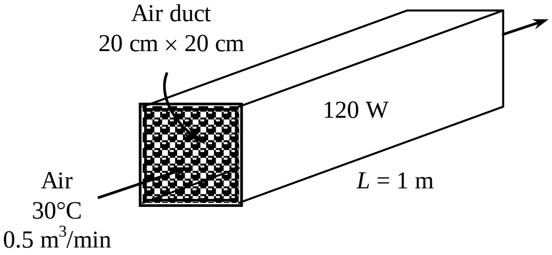
$$\dot{Q} = hA_s(T_{s,\max} - T_{fluid}) \longrightarrow T_{s,\max} = T_{air,out} + \frac{\dot{Q}}{hA_s} = 44.4\text{°C} + \frac{(75\times 0.15)\ \text{W}}{(37.1\ \text{W/m}^2.\text{°C})(0.03\ \text{m}^2)} = \mathbf{54.5°C}$$

15-115 The components of an electronic system located in a horizontal duct of rectangular cross-section are cooled by forced air flowing through the duct. The exit temperature of air and the highest component surface temperature in the duct are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas. **3** The local atmospheric pressure is 1 atm.

Properties We use the properties of air at 1 atm and 30°C (Table A-15)

$$\rho = 1.164 \text{ kg/m}^3$$
$$C_p = 1007 \text{ J/kg.°C}$$
$$\text{Pr} = 0.728$$
$$k = 0.0259 \text{ W/m.°C}$$
$$\nu = 1.61\times10^{-5} \text{ m}^2/\text{s}$$



Analysis (*a*) The rate of heat transfer from the components to the forced air in the duct is

$$\dot{Q} = (0.80)(120 \text{ W}) = 96 \text{ W}$$

The mass flow rate of air is

$$\dot{m} = \rho\dot{V} = (1.164 \text{ kg/m}^3)(0.5/60 \text{ m}^3/\text{s}) = 0.0097 \text{ kg/s}$$

Then the exit temperature of air is determined from

$$\dot{Q} = \dot{m}C_p(T_{out} - T_{in}) \longrightarrow T_{out} = T_{in} + \frac{\dot{Q}}{\dot{m}C_p} = 30°\text{C} + \frac{96 \text{ W}}{(0.0097 \text{ kg/s})(1007 \text{ J/kg.°C})} = \mathbf{39.8°C}$$

(*b*) The highest surface temperature can be determined from

$$\dot{Q}_{conv} = hA_s(T_s - T_{fluid})$$

But we first need to determine convection heat transfer coefficient,

$$A_s = (4)(1 \text{ m})(0.20 \text{ m}) = 0.8 \text{ m}^2$$

$$\mathbf{V} = \frac{\dot{V}}{A_c} = \frac{(0.5/60 \text{ m}^3/\text{s})}{(0.20 \text{ m})^2} = 0.208 \text{ m/s}$$

$$\text{Re} = \frac{\mathbf{V}D_h}{\nu} = \frac{(0.208 \text{ m/s})(0.20 \text{ m})}{1.61\times10^{-5} \text{ m}^2/\text{s}} = 2588$$

From Table 15-2,

$$Nu = 0.102\,\text{Re}^{0.675}\,\text{Pr}^{1/3} = (0.102)(2588)^{0.675}(0.728)^{1/3} = 18.5$$

$$h = \frac{k}{D_h}Nu = \frac{0.0259 \text{ W/m.°C}}{0.20 \text{ m}}(18.5) = 2.39 \text{ W/m}^2.°\text{C}$$

Then the highest component surface temperature in the duct becomes

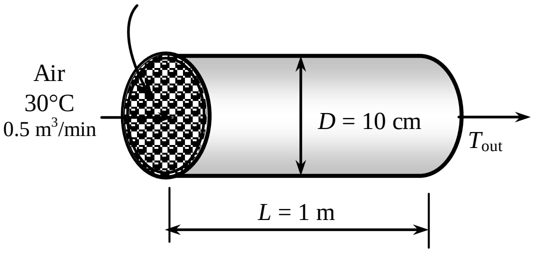
$$\dot{Q} = hA_s(T_{s,\max} - T_{air,out}) \longrightarrow T_{s,\max} = T_{air,out} + \frac{\dot{Q}}{hA_s} = 39.8°\text{C} + \frac{96 \text{ W}}{(2.39 \text{ W/m}^2.°\text{C})(0.8 \text{ m}^2)} = \mathbf{90.0°C}$$

15-116 The components of an electronic system located in a circular horizontal duct are cooled by forced air flowing through the duct. The exit temperature of air and the highest component surface temperature in the duct are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas. **3** The local atmospheric pressure is 1 atm.

Properties We use the properties of air at 1 atm and 30°C (Table A-15)

$$\rho = 1.164\ \text{kg/m}^3$$
$$C_p = 1007\ \text{J/kg.°C}$$
$$\text{Pr} = 0.728$$
$$k = 0.0259\ \text{W/m.°C}$$
$$\nu = 1.61\times10^{-5}\ \text{m}^2/\text{s}$$



Analysis (*a*) The rate of heat transfer from the components to the forced air in the duct is

$$\dot{Q} = (0.80)(120\ \text{W}) = 96\ \text{W}$$

The mass flow rate of air is

$$\dot{m} = \rho\dot{V} = (1.164\ \text{kg/m}^3)(0.5/60\ \text{m}^3/\text{s}) = 0.0097\ \text{kg/s}$$

Then the exit temperature of air is determined from

$$\dot{Q} = \dot{m}C_p(T_{out} - T_{in}) \longrightarrow T_{out} = T_{in} + \frac{\dot{Q}}{\dot{m}C_p} = 30°\text{C} + \frac{96\ \text{W}}{(0.0097\ \text{kg/s})(1007\ \text{J/kg.°C})} = \mathbf{39.8°C}$$

(*b*) The highest surface temperature can be determined from

$$\dot{Q}_{conv} = hA_s(T_s - T_{fluid})$$

But we first need to determine convection heat transfer coefficient,

$$A_s = \pi DL = \pi(0.1\ \text{m})(1\ \text{m}) = 0.314\ \text{m}^2$$

$$\mathbf{V} = \frac{\dot{V}}{A_c} = \frac{(0.5/60\ \text{m}^3/\text{s})}{\pi(0.10\ \text{m})^2/4} = 1.061\ \text{m/s}$$
$$\text{Re} = \frac{\mathbf{V}D}{\nu} = \frac{(1.061\ \text{m/s})(0.10\ \text{m})}{1.61\times10^{-5}\ \text{m}^2/\text{s}} = 6590$$

From Table 15-2,

$$Nu = 0.102\ \text{Re}^{0.675}\ \text{Pr}^{1/3} = (0.102)(6590)^{0.675}(0.728)^{1/3} = 34.7$$

$$h = \frac{k}{D_h}Nu = \frac{0.0259\ \text{W/m.°C}}{0.10\ \text{m}}(34.7) = 8.99\ \text{W/m}^2.°\text{C}$$

Then the highest component surface temperature in the duct becomes

$$\dot{Q} = hA_s(T_{s,\max} - T_{air,out}) \longrightarrow T_{s,\max} = T_{air,out} + \frac{\dot{Q}}{hA_s} = 39.8°\text{C} + \frac{96\ \text{W}}{(8.99\ \text{W/m}^2.°\text{C})(0.314\ \text{m}^2)} = \mathbf{73.8°C}$$

Liquid Cooling

15-117C When both are adequate, we would prefer forced air cooling in order to avoid the potential risks and problems associated with water cooling such as leakage, corrosion, extra weight, and condensation.

15-118C In direct cooling systems, the electronic components are in direct contact with the liquid, and thus the heat generated in the components is transferred directly to the liquid. In indirect cooling systems, however, there is no direct contact with the components. The heat generated in this case is first transferred to a medium such as a cold plate before it is removed by the liquid.

15-119C In closed loop cooling systems the liquid is recirculated while in the open loop systems the liquid is discarded after use. The heated liquid in closed loop systems is cooled in a heat exchanger, and it is recirculated through the system. In open loop systems, liquid (usually tap water) flows through the cooling system is discarded into a drain after it is heated.

15-120C The properties of a liquid ideally suited for cooling electronic equipment include high thermal conductivity, high specific heat, low viscosity, high surface tension, high dielectric strength, chemical inertness, chemical stability, being non toxic, having low freezing and high boiling points, and low cost.

15-121 A cold plate is to be cooled by water. The mass flow rate of water, the diameter of the pipe, and the case temperature of the transistors are to be determined.

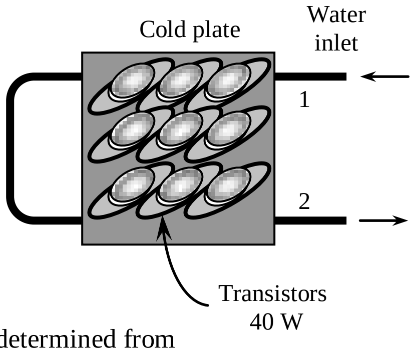
Assumptions **1** Steady operating conditions exist. **2** About 25 percent of the heat generated is dissipated from the components to the surroundings by convection and radiation.

Properties The properties of water at room temperature are ρ = 1000 kg/m^3 and C_p = 4180 J/kg.°C (Table A-9).

Analysis Noting that each of the 10 transistors dissipates 40 W of power and 75% of this power is removed by the water, the rate of heat transfer to the water is

$$\dot{Q} = (10 \text{ transistors})(40 \text{ W / transistor})(0.75) = 300 \text{ W}$$

In order to limit the temperature rise of water to $4\,^\circ\text{C}$, the mass flow rate of water must be no less than



$$\dot{m} = \frac{\dot{Q}}{C_p \Delta T_{\text{rise}}} = \frac{300\text{ W}}{(4180\text{ J/kg.°C})(4°\text{C})} = 0.0179\text{ kg/s} = \mathbf{1.08\ kg/min}$$

The diameter of the pipe to maintain the velocity under 0.5 m/s is determined from

$$\dot{m} = \rho A_c \mathbf{V} = \rho \frac{\pi D^2}{4} \mathbf{V}$$

$$D = \sqrt{\frac{4\dot{m}}{\pi \rho \mathbf{V}}} = \sqrt{\frac{4(0.0179\text{ kg/s})}{\pi (1000\text{ kg/m}^3)(0.5\text{ m/s})}} = 0.0068\text{ m} = \mathbf{0.68\ cm}$$

Noting that the case-to-liquid thermal resistance is 0.04 °C/W, the case temperature of the transistors is

$$\dot{Q} = \frac{T_{case} - T_{liquid}}{R_{case-liquid}} \longrightarrow T_{case} = T_{liquid} + \dot{Q}R_{case-liquid} = 25°\text{C} + (300\text{ W})(0.04\text{ °C/W}) = \mathbf{37°C}$$

ΔT_water [C]

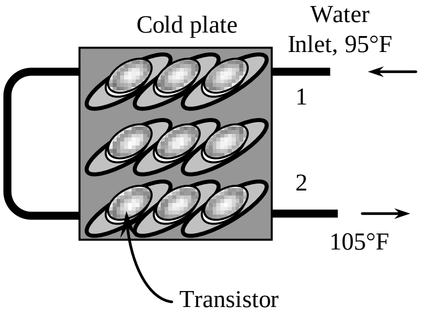
15-123E Electronic devices mounted on a cold plate is cooled by water. The amount of heat generated by the electronic devices is to be determined.



Assumptions **1** Steady operating conditions exist. **2** About 15 percent of the heat generated is dissipated from the components to the surroundings by convection and radiation.

Properties The properties of water at room temperature are ρ = 62.2 lbm/ft^3 and C_p = 0.998 Btu/lbm.°F.

Analysis The mass flow rate of water and the rate of heat removal by the water are

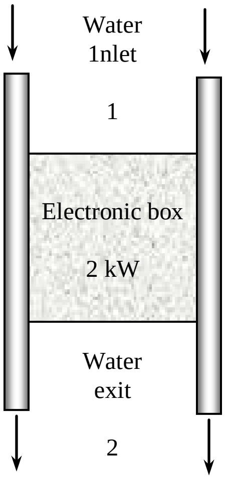
$$\dot{m} = \rho A_c \mathbf{V} = \rho \frac{\pi D^2}{4}\mathbf{V} = (62.2\ \text{lbm/ft}^3)\frac{\pi(0.25/12\ \text{ft})^2}{4}(60\ \text{ft/min}) = 1.272\ \text{lbm/min} = 76.33\ \text{lbm/h}$$

$$\dot{Q} = \dot{m}C_p(T_{out} - T_{in}) = (76.33\ \text{lbm/h})(0.998\ \text{Btu/lbm.°F})(105\text{-}95)\text{°F} = 761.8\ \text{Btu/h}$$

which is 85 percent of the heat generated by the electronic devices. Then the total amount of heat generated by the electronic devices becomes

$$\dot{Q} = \frac{761.8\ \text{Btu/h}}{0.85} = \mathbf{896\ Btu/h = 263\ W}$$

15-124 A sealed electronic box is to be cooled by tap water flowing through channels on two of its sides. The mass flow rate of water and the amount of water used per year are to be determined.



Assumptions **1** Steady operating conditions exist. **2** Entire heat generated is dissipated by water.

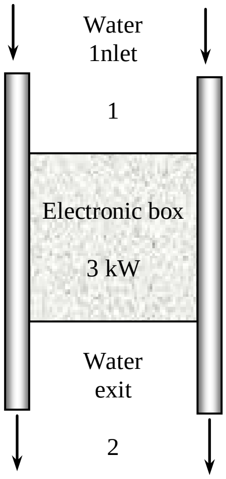
Properties The specific heat of water at room temperature is C_p = 4180 J/kg.°C.

Analysis The mass flow rate of tap water flowing through the electronic box is

$$\dot{Q} = \dot{m}C_p\Delta T \longrightarrow \dot{m} = \frac{\dot{Q}}{C_p\Delta T} = \frac{2\ \text{kJ/s}}{(4.18\ \text{kJ/kg.°C})(3\text{°C})} = \mathbf{0.1595\ kg/s}$$

Therefore, 0.1595 kg water is needed per second to cool this electronic box. Then the amount of cooling water used per year becomes

$$\begin{aligned} m = \dot{m}\Delta t &= (0.1595\ \text{kg/s})(365\ \text{days/yr} \times 24\ \text{h/day} \times 3600\ \text{s/h}) \\ &= 5{,}030{,}000\ \text{kg/yr} = \mathbf{5030\ tons/yr} \end{aligned}$$



15-125 A sealed electronic box is to be cooled by tap water flowing through channels on two of its sides. The mass flow rate of water and the amount of water used per year are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Entire heat generated is dissipated by water.

Properties The specific heat of water at room temperature is C_p = 4180 J/kg.°C.

Analysis The mass flow rate of tap water flowing through the electronic box is

$$\dot{Q} = \dot{m}C_p\Delta T \longrightarrow \dot{m} = \frac{\dot{Q}}{C_p\Delta T} = \frac{3\text{ kJ/s}}{(4.18\text{ kJ/kg.°C})(3\text{°C})} = \mathbf{0.2392\ kg/s}$$

Therefore, 0.2392 kg water is needed per second to cool this electronic box. Then the amount of cooling water used per year becomes

$$\begin{aligned} m &= \dot{m}\Delta t = (0.2392\text{ kg/s})(365\text{ days/yr}\times 24\text{ h/day}\times 3600\text{ s/h}) \\ &= 7{,}544{,}500\text{ kg/yr} = \mathbf{7545\ tons/yr} \end{aligned}$$

Immersion Cooling

15-126C The desirable characteristics of a dielectric liquid used in immersion cooling of electronic devices are non-flammability, being chemically inert, compatibility with materials used in electronic equipment, and low boiling and freezing points.

15-127C An open loop immersion cooling system involves an external reservoir which supplies liquid continually to the electronic enclosure. The vapor generated inside is allowed to escape to the atmosphere. A pressure relief valve on the vapor vent line keeps the pressure and thus the temperature inside the enclosure at a preset value. In a closed loop immersion system, the vapor is condensed and returned to the electronic enclosure instead of being purged into the atmosphere.

15-128C In external immersion cooling systems, the vapor is condensed outside the enclosure whereas in internal immersion cooling systems the vapor is condensed inside the enclosure by circulating a cooling fluid through the vapor. Therefore, in condenser is built into the enclosure in internal immersion cooling systems whereas it is placed outside in external immersion cooling systems.

15-129C The heat transfer coefficient is much greater in the boiling heat transfer than it is in the forced air or liquid cooling. Therefore, in the cooling of high-power electronic devices, boiling heat transfer is used to achieve high cooling rates with minimal temperature differences.

15-130 A logic chip is to be cooled by immersion in a dielectric fluid. The minimum heat transfer coefficient and the type of cooling mechanism are to be determined.

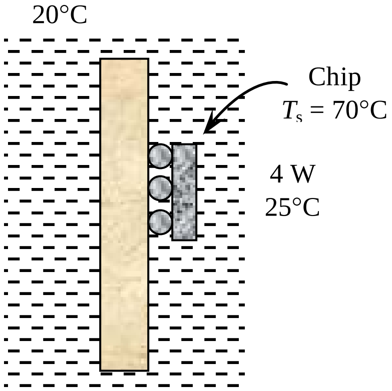
Assumptions Steady operating conditions exist.

Analysis The average heat transfer coefficient over the surface of the chip is determined from Newton's law of cooling to be

$$\dot{Q} = hA_s(T_{chip} - T_{fluid})$$

$$h = \frac{\dot{Q}}{A_s(T_{chip} - T_{fluid})} = \frac{4\text{ W}}{(0.3\times10^{-4}\text{ m}^2)(70-20)^\circ\text{C}} = \mathbf{2667\ W/m^2.^\circ C}$$

which is rather high. An examination of Fig. 15-62 reveals that we can obtain such heat transfer coefficients with the boiling of fluorocarbon fluids. Therefore, a suitable cooling technique in this case is immersion cooling in such a fluid.



15-131 A chip is cooled by boiling in a dielectric fluid. The surface temperature of the chip is to be determined.

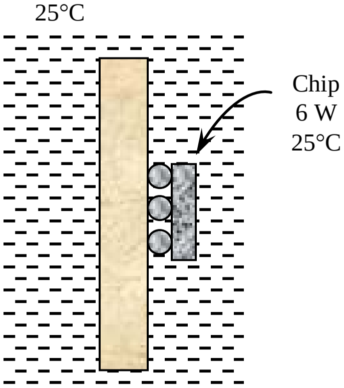
Assumptions The boiling curve in Fig. 15-63 is prepared for a chip having a surface area of 0.457 cm^2 being cooled in FC86 maintained at 5°C. The chart can be used for similar cases with reasonable accuracy.

Analysis The heat flux in this case is

$$\dot{q} = \frac{\dot{Q}}{A_s} = \frac{6\text{ W}}{0.5\text{ cm}^2} = 12\text{ W/cm}^2$$

The temperature of the chip surface corresponding to this heat flux is determined from Fig. 15-63 to be

$$T_{chip} - T_{fluid} = 57^\circ\text{C} \longrightarrow T_{chip} = (T_{fluid} + 57)^\circ\text{C} = (25+57)^\circ\text{C} = \mathbf{82^\circ C}$$



15-132 A logic chip is cooled by immersion in a dielectric fluid. The heat flux and the heat transfer coefficient on the surface of the chip and the thermal resistance between the surface of the chip and the cooling medium are to be determined.

Assumptions Steady operating conditions exist.

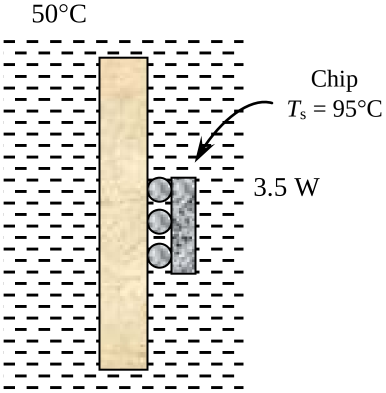
Analysis (*a*) The heat flux on the surface of the chip is

$$\dot{q} = \frac{\dot{Q}}{A_s} = \frac{3.5\text{ W}}{0.8\text{ cm}^2} = \mathbf{4.375\ W/cm^2}$$

(*b*) The heat transfer coefficient on the surface of the chip is

$$\dot{Q} = hA_s(T_{chip} - T_{fluid})$$

$$h = \frac{\dot{Q}}{A_s(T_{chip} - T_{fluid})} = \frac{3.5\text{ W}}{(0.8\times10^{-4}\text{ m}^2)(95-50)^\circ\text{C}} = \mathbf{972\ W/m^2.^\circ C}$$



(*c*) The thermal resistance between the surface of the chip and the cooling medium is

$$\dot{Q} = \frac{T_{chip} - T_{fluid}}{R_{chip-fluid}} \longrightarrow R_{chip-fluid} = \frac{T_{chip} - T_{fluid}}{\dot{Q}} = \frac{(95-50)^\circ\text{C}}{3.5\text{ W}} = \mathbf{12.9^\circ\ C/W}$$

$R_{ChipFluid}$ [C/W]
$\dot{Q}_{total}$ [W]

15-134 A computer chip is to be cooled by immersion in a dielectric fluid. The minimum heat transfer coefficient and the appropriate type of cooling mechanism are to be determined.

Assumptions Steady operating conditions exist.

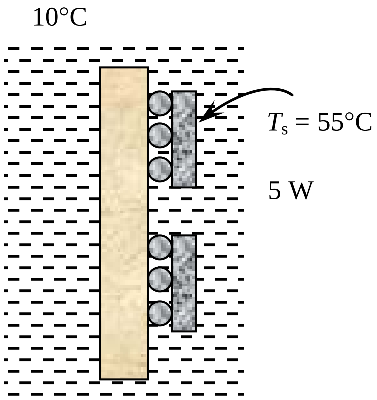
Analysis The average heat transfer coefficient over the surface of the chip is determined from Newton's law of cooling to be

$$\dot{Q} = hA_s(T_{chip} - T_{fluid})$$

$$h = \frac{\dot{Q}}{A_s(T_{chip} - T_{fluid})} = \frac{5\,\text{W}}{(0.4\times10^{-4}\ \text{m}^2)(55-10)^\circ\text{C}}$$

$$= \mathbf{2778\ W/m^2.^\circ C}$$

which is rather high. An examination of Fig. 15-62 reveals that we can obtain such heat transfer coefficients with the boiling of fluorocarbon fluids. Therefore, a suitable cooling technique in this case is immersion cooling in such a fluid.



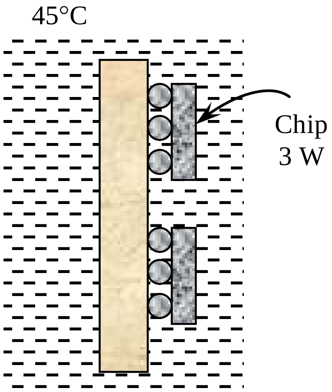
15-135 A chip is cooled by boiling in a dielectric fluid. The surface temperature of the chip is to be determined.

Assumptions The boiling curve in Fig. 15-63 is prepared for a chip having a surface area of 0.457 cm^2 being cooled in FC86 maintained at 5°C. The chart can be used for similar cases with reasonable accuracy.

Analysis The heat flux in this case is

$$\dot{q} = \frac{\dot{Q}}{A_s} = \frac{3\,\text{W}}{0.2\,\text{cm}^2} = 15\,\text{W/cm}^2$$

The temperature of the chip surface corresponding to this value is determined from Fig. 15-63 to be



$$T_{chip} - T_{fluid} = 63^\circ\text{C} \longrightarrow T_{chip} = (T_{fluid} + 63)^\circ\text{C} = (45+63)^\circ\text{C} = \mathbf{108^\circ C}$$

15-136 A chip is cooled by boiling in a dielectric fluid. The maximum power that the chip can dissipate safely is to be determined.

Assumptions The boiling curve in Fig. 15-63 is prepared for a chip having a surface area of 0.457 cm^2 being cooled in FC86 maintained at 5°C. The chart can be used for similar cases with reasonable accuracy.

Analysis The temperature difference between the chip surface and the liquid is

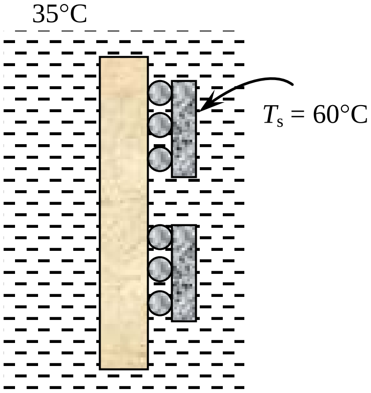
$$T_{chip} - T_{fluid} = (60 - 35)^\circ\text{C} = 25^\circ\text{C}$$

Using this value, the heat flux can be determined from Fig. 15-63 to be

$$\dot{q} = 3.3\,\text{W/cm}^2$$

Then the maximum power that the chip can dissipate safely becomes

$$\dot{Q} = \dot{q}A_s = (3.3\,\text{W/cm}^2)(0.3\,\text{cm}^2) = \mathbf{0.99\ W}$$



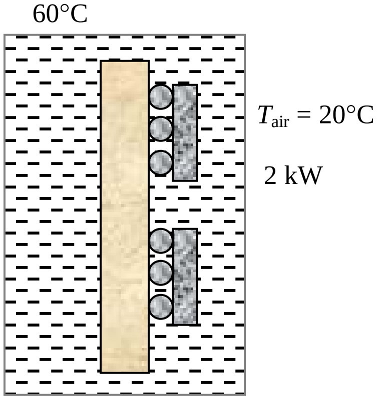
15-137 An electronic device is to be cooled by immersion in a dielectric fluid. It is to be determined if the heat generated inside can be dissipated to the ambient air by natural convection and radiation as well as the heat transfer coefficient at the surface of the electronic device.

Assumptions Steady operating conditions exist.

Analysis Assuming the surfaces of the cubic enclosure to be at the temperature of the boiling dielectric fluid at 60°C, the rate at which heat can be dissipated to the ambient air at 20°C by combined natural convection and radiation is determined from

$$\dot{Q} = hA_s(T_s - T_{air}) = h(6a^2)(T_s - T_{air})$$
$$= (10\,\text{W/m}^2.^\circ\text{C})[6(1\,\text{m})^2](60 - 20)^\circ\text{C} = 2400\,\text{W} = \mathbf{2.4\ kW}$$

Therefore, the heat generated inside the cubic enclosure can be dissipated by natural convection and radiation. The heat transfer coefficient at the surface of the electronic device is



$$\dot{Q} = hA_s(T_s - T_{fluid}) \longrightarrow h = \frac{\dot{Q}}{A_s(T_s - T_{fluid})} = \frac{2000\,\text{W}}{(0.012\,\text{m}^2)(80 - 60)^\circ\text{C}} = \mathbf{8333\ W/m^2.^\circ C}$$

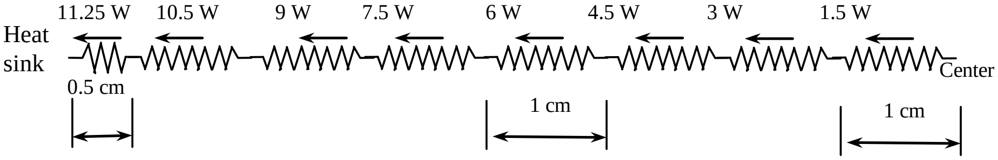
Review Problems

15-138C For most effective cooling, (1) the transistors must be mounted directly over the cooling lines, (2) the thermal contact resistance between the transistors and the cold plate must be minimized by attaching them tightly with a thermal grease, and (3) the thickness of the plates and the tubes should be as small as possible to minimize the thermal resistance between the transistors and the tubes.

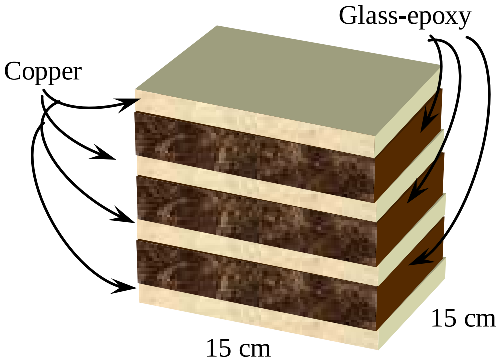
15-139C There is no such thing as heat rising. Only heated fluid rises because of lower density due to buoyancy. Heat conduction in a solid is due to the molecular vibrations and electron movement, and gravitational force has no effect on it. Therefore, the orientation of the bar is irrelevant.

15-140 A multilayer circuit board consisting of four layers of copper and three layers of glass-epoxy sandwiched together is considered. The magnitude and location of the maximum temperature that occurs in the PCB are to be determined.

Assumptions **1** Steady operating conditions exist **2** Thermal properties are constant. **3** There is no direct heat dissipation from the surface of the PCB, and thus all the heat generated is conducted by the PCB to the heat sink.



Analysis The effective thermal conductivity of the board is determined from



$$(k_1t_1)_{copper} = 4[(386\text{ W/m.°C})(0.0001\text{ m})] = 0.1544\text{ W/°C}$$

$$(k_2t_2)_{epoxy} = 3[(0.26\text{ W/m.°C})(0.0005\text{ m})] = 0.00039\text{ W/°C}$$

$$k_{eff} = \frac{(k_1t_1)_{copper} + (k_2t_2)_{epoxy}}{t_1 + t_2} = \frac{(0.1544 + 0.00039)\text{W/°C}}{4(0.0001\text{ m}) + 3(0.0005\text{ m})}$$
$$= 81.5\text{ W/m.°C}$$

The maximum temperature will occur in the middle of the board which is farthest away from the heat sink. We consider half of the board because of symmetry, and divide the region in 1-cm thick strips, starting at the mid-plane. Then from Fourier's law, the temperature difference across a strip can be determined from

$$\dot{Q} = k_{eff}A\frac{\Delta T}{L} \longrightarrow \Delta T = \frac{\dot{Q}L}{k_{eff}A}$$

where L = 1 cm = 0.01 m (except it is 0.5 cm for the strip attached to the heat sink), and the heat transfer area for all the strips is

$$A = (0.15\text{ m})[4(0.0001\text{ m}) + 3(0.0005\text{ m})] = 0.000285\text{ m}^2$$

Then the temperature at the center of the board is determined by adding the temperature differences across all the strips as

$$\Delta T_{\text{center-heat sink}} = \sum\frac{\dot{Q}L}{k_{eff}A} = \frac{(\dot{Q}_1 + \dot{Q}_2 + \dot{Q}_3 + \dot{Q}_4 + \dot{Q}_5 + \dot{Q}_6 + \dot{Q}_7 + \dot{Q}_8/2)L}{k_{eff}A}$$
$$= \frac{(1.5 + 3 + 4.5 + 6 + 7.5 + 9 + 10.5 + 11.25/2\text{ W})(0.01\text{ m})}{(81.5\text{ W/m.°C})(0.000285\text{ m}^2)} = 20.5\text{°C}$$

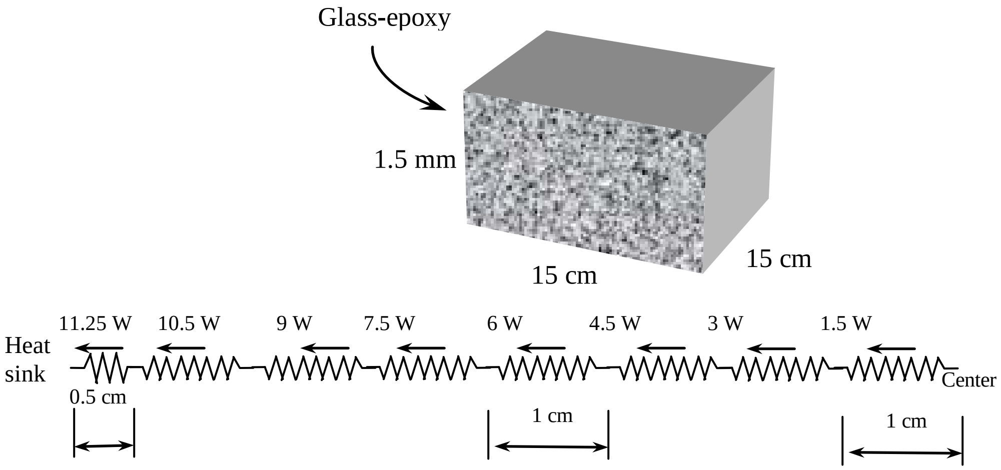
and $T_{\text{center}} = T_{\text{heat sink}} + \Delta T_{\text{center-heat sink}} = 35\text{°C} + 20.5\text{°C} = \mathbf{55.5°C}$

Discussion This problem can also be solved approximately by using the "average" heat transfer rate for the entire half board, and treating it as a constant. The heat transfer rate in each half changes from 0 at the center to 22.5/2 = 11.25 W at the heat sink, with an average of 11.25/2 = 5.625 W. Then the center temperature becomes

$$\dot{Q}_{ave} \cong k_{eff}A\frac{T_1 - T_2}{L} \longrightarrow T_{\text{center}} \cong T_{\text{heat sink}} + \frac{\dot{Q}_{ave}L}{k_{eff}A} = 35\text{°C} + \frac{(5.625\text{ W})(0.075\text{ m})}{(81.5\text{ W/m.°C})(0.000285\text{ m}^2)} = \mathbf{53.2°C}$$

15-141 A circuit board consisting of a single layer of glass-epoxy is considered. The magnitude and location of the maximum temperature that occurs in the PCB are to be determined.

Assumptions **1** Steady operating conditions exist **2** Thermal properties are constant. **3** There is no direct heat dissipation from the surface of the PCB, and thus all the heat generated is conducted by the PCB to the heat sink.



Analysis In this case the board consists of a 1.5-mm thick layer of epoxy. Again the maximum temperature will occur in the middle of the board which is farthest away from the heat sink. We consider half of the board because of symmetry, and divide the region in 1-cm thick strips, starting at the mid-plane. Then from Fourier's law, the temperature difference across a strip can be determined from

$$\dot{Q} = k_{eff} A \frac{\Delta T}{L} \longrightarrow \Delta T = \frac{\dot{Q} L}{k_{eff} A}$$

where L = 1 cm = 0.01 m (except it is 0.5 cm for the strip attached to the heat sink), and the heat transfer area for all the strips is

$$A = (0.15 \text{ m})(0.0015 \text{ m}) = 0.000225 \text{ m}^2$$

Then the temperature at the center of the board is determined by adding the temperature differences across all the strips as

$$\Delta T_{\text{center}-\text{heat sink}} = \sum \frac{\dot{Q} L}{k_{eff} A} = \frac{(\dot{Q}_1 + \dot{Q}_2 + \dot{Q}_3 + \dot{Q}_4 + \dot{Q}_5 + \dot{Q}_6 + \dot{Q}_7 + \dot{Q}_8 / 2) L}{k_{eff} A}$$

$$= \frac{(1.5 + 3 + 4.5 + 6 + 7.5 + 9 + 10.5 + 11.25/2 \text{ W})(0.01 \text{ m})}{(0.26 \text{ W/m.}^\circ\text{C})(0.000225 \text{ m}^2)} = 8141^\circ\text{C}$$

and $T_{\text{center}} = T_{\text{heat sink}} + \Delta T_{\text{center}-\text{heat sink}} = 35^\circ\text{C} + 8141^\circ\text{C} = \mathbf{8176^\circ C}$

Discussion This problem can also be solved approximately by using the "average" heat transfer rate for the entire half board, and treating it as a constant. The heat transfer rate in each half changes from 0 at the center to 22.5/2 = 11.25 W at the heat sink, with an average of 11.25/2 = 5.625 W. Then the center temperature becomes

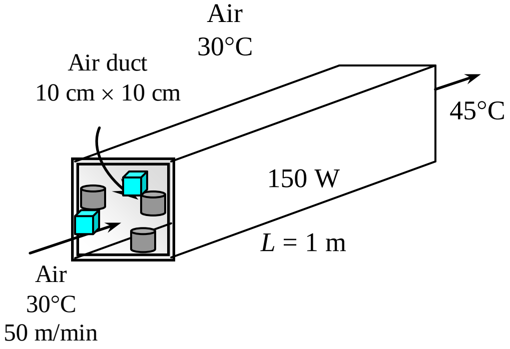
$$\dot{Q}_{ave} \cong k_{eff} A \frac{T_1 - T_2}{L} \longrightarrow T_{\text{center}} \cong T_{\text{heat sink}} + \frac{\dot{Q}_{ave} L}{k_{eff} A} = 35^\circ\text{C} + \frac{(5.625 \text{ W})(0.075 \text{ m})}{(0.26 \text{ W/m.}^\circ\text{C})(0.000225 \text{ m}^2)} = \mathbf{7247^\circ C}$$

15-142 The components of an electronic system located in a horizontal duct of rectangular cross-section are cooled by forced air flowing through the duct. The heat transfer from the outer surfaces of the duct by natural convection, the average temperature of the duct and the highest component surface temperature in the duct are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas. **3** The local atmospheric pressure is 1 atm.

Properties We use the properties of air at (30+45)/2 = 37.5°C are (Table A-15)

$$\rho = 1.136 \text{ kg/m}^3$$
$$C_p = 1007 \text{ J/kg.°C}$$
$$\text{Pr} = 0.726$$
$$k = 0.0264 \text{ W/m.°C}$$
$$\nu = 1.68\times 10^{-5} \text{ m}^2/\text{s}$$



Analysis (*a*) The volume and the mass flow rates of air are

$$\dot{V} = A_c\mathbf{V} = (0.1\text{ m})(0.1\text{ m})(50/60\text{ m/s}) = 0.008333\text{ m}^3/\text{s}$$
$$\dot{m} = \rho\dot{V} = (1.136\text{ kg/m}^3)(0.008333\text{ m}^3/\text{s}) = 0.009466\text{ kg/s}$$

The rate of heat transfer to the air flowing through the duct is

$$\dot{Q}_{forced\ conv} = \dot{m}C_p(T_{in} - T_{out}) = (0.009466\text{ kg/s})(1007\text{ J/kg.°C})(45 - 30)\text{°C} = 143.0\text{ W}$$

Then the rate of heat loss from the outer surfaces of the duct to the ambient air by natural convection becomes

$$\dot{Q}_{conv} = \dot{Q}_{total} - \dot{Q}_{forced\ conv} = 150\text{ W} - 143\text{ W} = \mathbf{57\ W}$$

(*b*) The average surface temperature can be determined from

$$\dot{Q}_{conv} = hA_s(T_{s,duct} - T_{\substack{ambient\\air}})$$

But we first need to determine convection heat transfer coefficient. Using the Nusselt number relation from Table 15-2,

$$A_s = (4)(0.1\text{ m})(1\text{ m}) = 0.4\text{ m}^2$$
$$\text{Re} = \frac{\mathbf{V}D_h}{\nu} = \frac{(50/60\text{ m/s})(0.1\text{ m})}{1.68\times 10^{-5}\text{ m}^2/\text{s}} = 4960$$
$$Nu = 0.102\,\text{Re}^{0.675}\,\text{Pr}^{1/3} = (0.102)(4960)^{0.675}(0.726)^{1/3} = 28.6$$
$$h = \frac{k}{D_h}Nu = \frac{0.0264\text{ W/m.°C}}{0.1\text{ m}}(28.6) = 7.56\text{ W/m}^2.\text{°C}$$

Then the average surface temperature of the duct becomes

$$\dot{Q}_{conv} = hA_s(T_s - T_{ambient}) \longrightarrow T_s = T_{ambient} + \frac{\dot{Q}_{conv}}{hA_s} = 30\text{°C} + \frac{57\text{ W}}{(7.56\text{ W/m}^2.\text{°C})(0.4\text{ m}^2)} = \mathbf{48.9°C}$$

(*c*) The highest component surface temperature will occur at the exit of the duct. From Newton's law relation at the exit,

$$\dot{q}_{conv} = h(T_{s,\max} - T_{air,exit}) \longrightarrow T_{s,\max} = T_{air,exit} + \frac{\dot{Q}_{conv}/A_s}{h} = 45\text{°C} + \frac{57\text{ W}}{(7.56\text{ W/m}^2.\text{°C})(0.4\text{ m}^2)} = \mathbf{63.8°C}$$

15-143 Two power transistors are cooled by mounting them on the two sides of an aluminum bracket that is attached to a liquid-cooled plate. The temperature of the transistor case and the fraction of heat dissipation to the ambient air by natural convection and to the cold plate by conduction are to be determined.

Assumptions **1** Steady operating conditions exist **2** Conduction heat transfer is one-dimensional. **3** We assume the ambient temperature is 25°C.

Analysis The rate of heat transfer by conduction is

$$\dot{Q}_{conduction} = (0.80)(12 \text{ W}) = 9.6 \text{ W}$$

Assuming heat conduction in the plate to be one-dimensional for simplicity, the thermal resistance of the aluminum plate and epoxy adhesive are

$$R_{alu\min um} = \frac{L}{kA} = \frac{0.02 \text{ m}}{(237 \text{ W/m.}^\circ\text{C})(0.003 \text{ m})(0.03 \text{ m})} = 0.938^\circ\text{C/W}$$

$$R_{epoxy} = \frac{L}{kA} = \frac{0.0002 \text{ m}}{(1.8 \text{ W/m.}^\circ\text{C})(0.003 \text{ m})(0.03 \text{ m})} = 1.235^\circ\text{C/W}$$

The total thermal resistance of the plate and the epoxy is

$$R_{plate+epoxy} = R_{epoxy} + R_{plate} = 1.235 + 0.938 = 2.173^\circ\text{C/W}$$

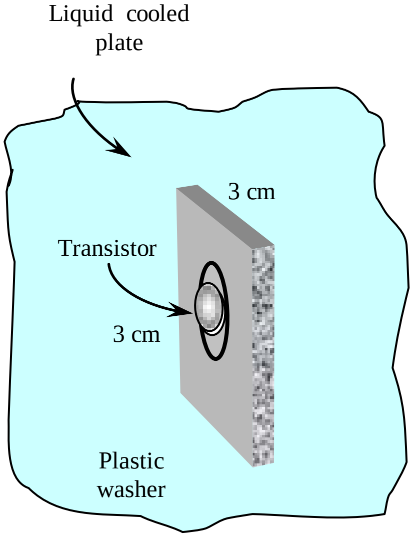
Heat generated by the transistors is conducted to the plate, and then it is dissipated to the cold plate by conduction, and to the ambient air by convection. Denoting the plate temperature where the transistors are connected as $T_{s,\max}$ and using the heat transfer coefficient relation from Table 15-1 for a vertical plate, the total heat transfer from the plate can be expressed as

$$\dot{Q}_{total} = \dot{Q}_{cond} + \dot{Q}_{conv} = \frac{\Delta T_{plate}}{R_{plate+epoxy}} + hA_{side}(T_{s,ave} - T_{air})$$

$$= \frac{T_{s,\max} - T_{cold\ plate}}{R_{plate+epoxy}} + 1.42\left(\frac{(T_{s,ave} - T_{air})}{L}\right)^{0.25} A_{side}(T_{s,\max} - T_{air})$$

where $T_{s,\text{ ave}} = (T_{s,\text{ max}} + T_{\text{cold plate}})/2$, L 0.03 m, and $A_{\text{side}} = 2(0.03 \text{ m})(0.03 \text{ m}) = 0.00018 \text{ m}^2$. Substituting the known quantities gives

$$20 \text{ W} = \frac{T_{s,\max} - 40}{2.173^\circ\text{C/W}} + 1.42(0.00018)\frac{[(T_{s,\max} + 40)/2 - 25]^{1.25}}{(0.03)^{0.25}}$$



Solving for $T_{s,\text{ max}}$ gives

$$T_{s,\text{ max}} = 83.3^\circ\text{C}$$

Then the rate of heat transfer by natural convection becomes

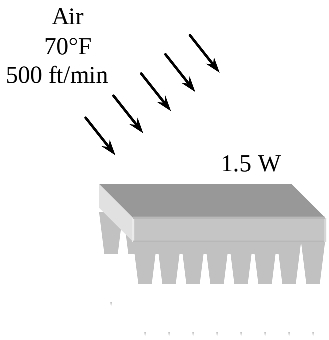
$$\dot{Q}_{conv} = 1.42(0.00018)\frac{[(83.3 + 40)/2 - 25]^{1.25}}{(0.03)^{0.25}} = 0.055 \text{ W}$$

which is 0.055/20 = 0.00275 or **0.3%** of the total heat dissipated. The remaining **99.7%** of the heat is transferred by conduction. Therefore, heat transfer by natural convection is negligible. Then the surface temperature of the transistor case becomes

$$T_{\text{case}} = T_{s,\max} + \dot{Q}R_{\text{plastic washer}} = 83.3^\circ\text{C} + (10 \text{ W})(2^\circ\text{C/W}) = \mathbf{103.3^\circ C}$$

15-144E A plastic DIP with 24 leads is cooled by forced air. Using data supplied by the manufacturer, the junction temperature is to be determined for two cases.

Assumptions Steady operating conditions exist.



Analysis The junction-to-ambient thermal resistance of the device with 24 leads corresponding to an air velocity of 500 × 0.3048 = 152.4 m/min is determined from Fig. 15-23 to be

$$R_{junction-ambient} = 50\ ^\circ\text{C/W} = (50 \times 1.8) + 32 = 122\ ^\circ\text{F/W}$$

Then the junction temperature becomes

$$\dot{Q} = \frac{T_{junction} - T_{ambient}}{R_{junction-ambient}} \longrightarrow T_{junction} = T_{ambient} + \dot{Q}R_{junction-ambient}$$

$$= 70°\text{F} + (1.5\text{ W})(122\ °\text{F/W}) = \mathbf{253°F}$$

When the fan fails the total thermal resistance is determined from Fig. 15-23 by reading the value at the intersection of the curve at the vertical axis to be

$$R_{junction-ambient} = 66\ ^\circ\text{C/W} = (66 \times 1.8) + 32 = 150.8\ ^\circ\text{F/W}$$

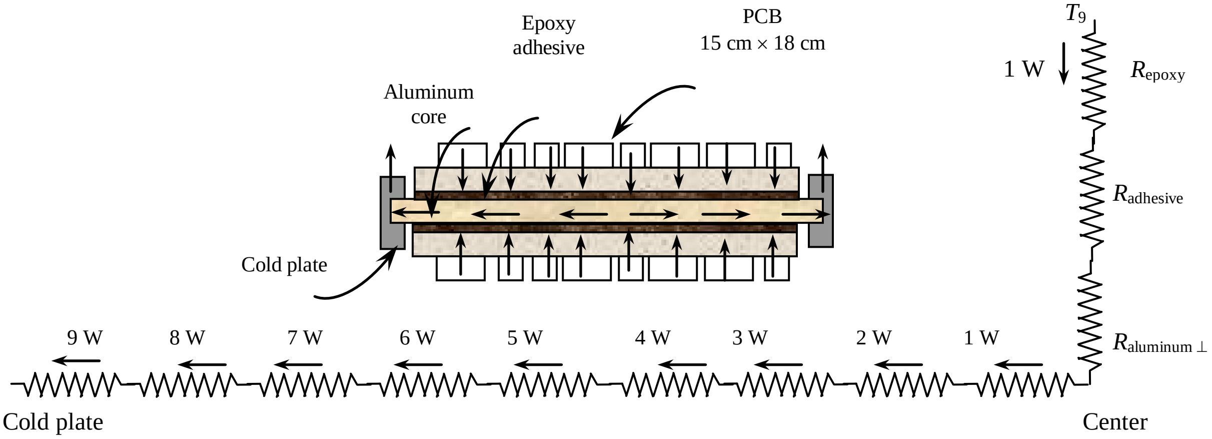
which yields

$$\dot{Q} = \frac{T_{junction} - T_{ambient}}{R_{junction-ambient}} \longrightarrow T_{junction} = T_{ambient} + \dot{Q}R_{junction-ambient}$$

$$= 70°\text{F} + (1.5\text{ W})(150.8\ °\text{F/W}) = \mathbf{296°F}$$

15-145 A circuit board is to be conduction-cooled by aluminum core plate sandwiched between two epoxy laminates. The maximum temperature rise between the center and the sides of the PCB is to be determined.

Assumptions **1** Steady operating conditions exist **2** Thermal properties are constant. **3** There is no direct heat dissipation from the surface of the PCB., and thus all the heat generated is conducted by the PCB to the heat sink.



Analysis Using the half thickness of the aluminum frame because of symmetry, the thermal resistances against heat flow in the vertical direction for a 1-cm wide strip are

$$R_{\text{aluminum},\perp}=\frac{L}{kA}=\frac{0.0006\text{ m}}{(237\text{ W/m.}^\circ\text{C})(0.01\text{ m})(0.15\text{ m})}=0.00169\ ^\circ\text{C/W}$$

$$R_{\text{epoxy}}=\frac{L}{kA}=\frac{0.0005\text{ m}}{(0.26\text{ W/m.}^\circ\text{C})(0.01\text{ m})(0.15\text{ m})}=1.28205\ ^\circ\text{C/W}$$

$$R_{\text{adhesive}}=\frac{L}{kA}=\frac{0.0001\text{ m}}{(1.8\text{ W/m.}^\circ\text{C})(0.01\text{ m})(0.15\text{ m})}=0.03703\ ^\circ\text{C/W}$$

$$R_{\text{vertical}}=R_{\text{aluminum},\perp}+R_{\text{epoxy}}+R_{\text{adhesive}}=0.00169+1.28205+0.03704=1.321\ ^\circ\text{C/W}$$

We assume heat conduction along the epoxy and adhesive in the horizontal direction to be negligible, and heat to be conduction to the heat sink along the aluminum frame. The thermal resistance of the aluminum frame against heat conduction in the horizontal direction for a 1-cm long strip is

$$R_{\text{frame}}=R_{\text{aluminum},\parallel}=\frac{L}{kA}=\frac{0.01\text{ m}}{(237\text{ W/m.}^\circ\text{C})(0.0012\text{ m})(0.18\text{ m})}=0.1953\ ^\circ\text{C/W}$$

The temperature difference across a strip is determined from

$$\Delta T=\dot{Q}R_{\text{aluminum},\parallel}$$

The maximum temperature rise across the 9 cm distance between the center and the sides of the board is determined by adding the temperature differences across all the strips as

$$\begin{aligned}\Delta T_{\text{horizontal}}&=\sum\dot{Q}R_{\text{aluminum},\parallel}=(\dot{Q}_1+\dot{Q}_2+\dot{Q}_3+\dot{Q}_4+\dot{Q}_5+\dot{Q}_6+\dot{Q}_7+\dot{Q}_8 2)R_{\text{aluminum},\parallel}\\&=(1+2+3+4+5+6+7+8+9\text{ W})(0.1953\ ^\circ\text{C/W})=8.8^\circ\text{C}\end{aligned}$$

The temperature difference between the center of the aluminum core and the outer surface of the PCB is determined similarly to be

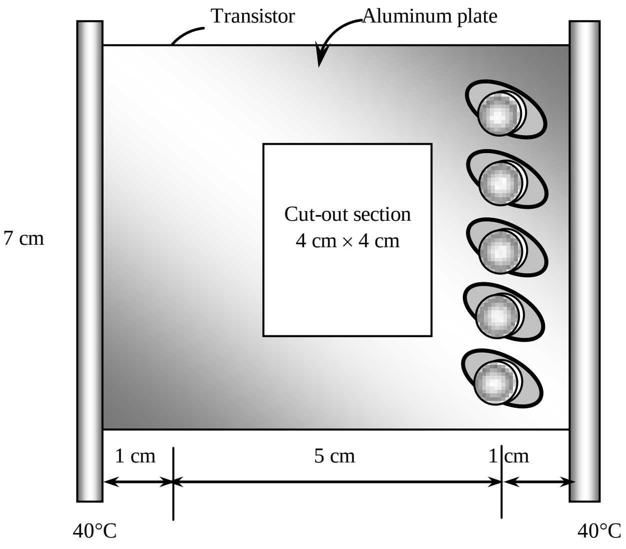
$$\Delta T_{\text{vertical}}=\sum\dot{Q}R_{\text{vertical},\perp}=(1\text{ W})(1.321\ ^\circ\text{C/W})=1.3^\circ\text{C}$$

Then the maximum temperature rise across the 9-cm distance between the center and the sides of the PCB becomes

$$\Delta T_{\max}=\Delta T_{\text{horizontal}}+\Delta T_{\text{vertical}}=8.8+1.3=\mathbf{10.1^\circ C}$$

15-146 Ten power transistors attached to an aluminum plate are cooled from two sides of the plate by liquid. The temperature rise between the transistors and the heat sink is to be determined.

Assumptions **1** Steady operating conditions exist **2** Thermal properties are constant.



Analysis We consider only half of the plate because of symmetry. It is stated that 70% of the heat generated is conducted through the aluminum plate, and this heat will be conducted across the 1-cm wide section between the transistors and the cooled edge of the plate. (Note that the mid section of the plate will essentially be isothermal and thus there will be no significant heat transfer towards the midsection). The rate of heat conduction to each side is of the plate is

$$\dot{Q}_{\text{cond,1-side}} = 0.70 \times (10\text{ W}) = 7\text{ W}$$

Then the temperature rise across the 1-cm wide section of the plate can be determined from

$$\dot{Q}_{\text{cond. 1-side}} = kA\frac{(\Delta T)_{\text{plate}}}{L}$$

Solving for $(\Delta T)_{\text{plate}}$ and substituting gives

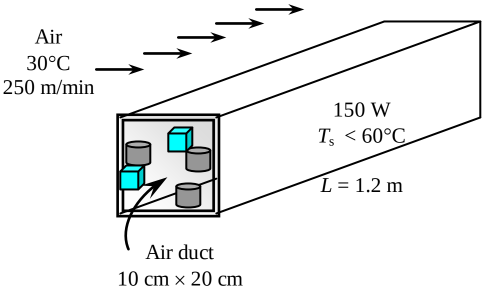
$$(\Delta T)_{\text{plate}} = \frac{\dot{Q}_{\text{cond.1-side}}L}{kA} = \frac{(7\text{ W})(0.01\text{ m})}{(237\text{ W/m.°C})(0.07 \times 0.002\text{ m}^2)} = \mathbf{2.1°C}$$

15-147 The components of an electronic system located in a horizontal duct are cooled by air flowing over the duct. The total power rating of the electronic devices that can be mounted in the duct is to be determined for two cases.

Assumptions **1** Steady operating conditions exist **2** Thermal properties of air are constant. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at the film temperature of (30+60)/2 = 45°C are (Table A-15)

$$\mathrm{Pr} = 0.724$$
$$k = 0.0270\ \mathrm{W/m.°C}$$
$$\nu = 1.75\times10^{-5}\ \mathrm{m^2/s}$$



Analysis The surface area of the duct is

$$A_s = 2\{[(1.2\ \mathrm{m})(0.1\ \mathrm{m})] + [(1.2\ \mathrm{m})(0.2\ \mathrm{m})]\} = 0.72\ \mathrm{m}^2$$

The duct is oriented such that air strikes the 10 cm high side normally. Using the Nusselt number relation from Table 15-2 for a 10-cm by 10-cm cross-section square as an approximation, the heat transfer coefficient is determined to be

$$\mathrm{Re} = \frac{\mathbf{V}D}{\nu} = \frac{(250/60\ \mathrm{m/s})(0.1\ \mathrm{m})}{1.75\times10^{-5}\ \mathrm{m^2/s}} = 23{,}810$$

$$Nu = 0.102\,\mathrm{Re}^{0.675}\,\mathrm{Pr}^{1/3} = (0.102)(23{,}810)^{0.675}(0.724)^{1/3} = 82.4$$

$$h = \frac{k}{D_h}Nu = \frac{0.0270\ \mathrm{W/m.°C}}{0.1\ \mathrm{m}}(82.4) = 22.3\ \mathrm{W/m^2.°C}$$

Then the heat transfer rate (and thus the power rating of the components inside) in this orientation is determined from

$$\dot{Q} = hA_s(T_s - T_{fluid}) = (22.3\ \mathrm{W/m^2.°C})(0.72\ \mathrm{m^2})(60-30)\mathrm{°C} = \mathbf{481\ W}$$

We now consider the duct oriented such that air strikes the 20 cm high side normally. Using the Nusselt number relation from Table 15-2 for a 20-cm by 20-cm cross-section square as an approximation, the heat transfer coefficient is determined to be

$$\mathrm{Re} = \frac{\mathbf{V}D}{\nu} = \frac{(250/60\ \mathrm{m/s})(0.2\ \mathrm{m})}{1.75\times10^{-5}\ \mathrm{m^2/s}} = 47{,}619$$

$$Nu = 0.102\,\mathrm{Re}^{0.675}\,\mathrm{Pr}^{1/3} = (0.102)(47{,}619)^{0.675}(0.724)^{1/3} = 131.6$$

$$h = \frac{k}{D_h}Nu = \frac{0.0270\ \mathrm{W/m.°C}}{0.2\ \mathrm{m}}(131.6) = 17.8\ \mathrm{W/m^2.°C}$$

Then the heat transfer rate (and thus the power rating of the components inside) in this orientation is determined from

$$\dot{Q} = hA_s(T_s - T_{fluid}) = (17.8\ \mathrm{W/m^2.°C})(0.72\ \mathrm{m^2})(60-30)\mathrm{°C} = \mathbf{384\ W}$$

15-148 The components of an electronic system located in a horizontal duct are cooled by air flowing over the duct. The total power rating of the electronic devices that can be mounted in the duct is to be determined for two cases.

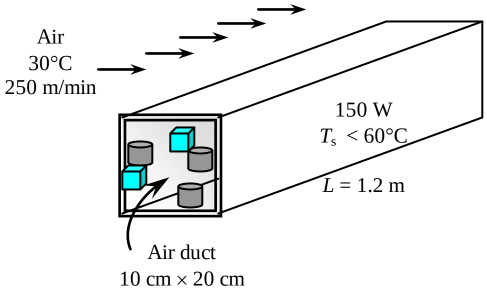
Assumptions **1** Steady operating conditions exist **2** Thermal properties of air are constant. **3** The local atmospheric pressure is 1 atm.

Properties The properties of air at the film temperature of (30+60)/2 = 45°C and 54.05 kPa are (Table A-15)

$$\Pr = 0.724$$

$$k = 0.0270 \text{ W/m.°C}$$

$$\nu = \frac{1.75\times10^{-5} \text{ m}^2/\text{s}}{54.05/101.325} = 3.28\times10^{-5} \text{ m}^2/\text{s}$$



Analysis The surface area of the duct is

$$A_s = 2\{[(1.2\text{ m})(0.1\text{ m})] + [(1.2\text{ m})(0.2\text{ m})]\} = 0.72 \text{ m}^2$$

The duct is oriented such that air strikes the 10 cm high side normally. Using the Nusselt number relation from Table 15-2 for a 10-cm by 10-cm cross-section square as an approximation, the heat transfer coefficient is determined to be

$$\text{Re} = \frac{\mathbf{V}D}{\nu} = \frac{(250/60 \text{ m/s})(0.1\text{ m})}{3.28\times10^{-5} \text{ m}^2/\text{s}} = 12{,}703$$

$$Nu = 0.102\,\text{Re}^{0.675}\,\Pr^{1/3} = (0.102)(12{,}703)^{0.675}(0.724)^{1/3} = 53.9$$

$$h = \frac{k}{D_h} Nu = \frac{0.0270 \text{ W/m.°C}}{0.1\text{ m}}(53.9) = 14.6 \text{ W/m}^2.\text{°C}$$

Then the heat transfer rate (and thus the power rating of the components inside) in this orientation is determined from

$$\dot{Q} = hA_s(T_s - T_{fluid}) = (14.6 \text{ W/m}^2.\text{°C})(0.72 \text{ m}^2)(60-30)\text{°C} = \mathbf{315 \text{ W}}$$

We now consider the duct oriented such that air strikes the 20 cm high side normally. Using the Nusselt number relation from Table 15-2 for a 20-cm by 20-cm cross-section square as an approximation, the heat transfer coefficient is determined to be

$$\text{Re} = \frac{\mathbf{V}D}{\nu} = \frac{(250/60 \text{ m/s})(0.2\text{ m})}{3.28\times10^{-5} \text{ m}^2/\text{s}} = 25{,}407$$

$$Nu = 0.102\,\text{Re}^{0.675}\,\Pr^{1/3} = (0.102)(25{,}407)^{0.675}(0.724)^{1/3} = 86.1$$

$$h = \frac{k}{D_h} Nu = \frac{0.0270 \text{ W/m.°C}}{0.2\text{ m}}(86.1) = 11.6 \text{ W/m}^2.\text{°C}$$

Then the heat transfer rate (and thus the power rating of the components inside) in this orientation is determined from

$$\dot{Q} = hA_s(T_s - T_{fluid}) = (11.6 \text{ W/m}^2.\text{°C})(0.72 \text{ m}^2)(60-30)\text{°C} = \mathbf{251 \text{ W}}$$

15-149E A computer is cooled by a fan blowing air into the computer enclosure. The fraction of heat lost from the outer surfaces of the computer case is to be determined.

Assumptions **1** Steady operating conditions exist **2** Thermal properties of air are constant. **3** The local atmospheric pressure is 1 atm.

Analysis Using the proper relation from Table 15-1, the heat transfer coefficient and the rate of natural convection heat transfer from the vertical side surfaces are determined to be

$$L = \frac{6}{12}\text{ ft}$$

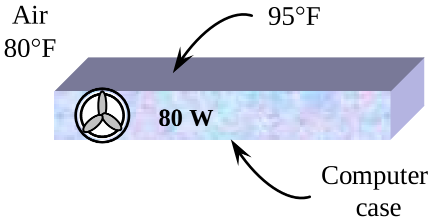
$$A_{side} = (2)\left(\frac{20}{12}\text{ ft} + \frac{24}{12}\text{ ft}\right)\left(\frac{6}{12}\text{ ft}\right) = 3.67\text{ ft}^2$$

$$h_{conv,side} = 1.42\left(\frac{\Delta T}{L}\right)^{0.25} = 1.42\left(\frac{95-80}{6/12}\right)^{0.25} = 3.32\text{ Btu/h.ft}^2.°\text{F}$$

$$\dot{Q}_{conv,side} = h_{conv,side}A_{side}(T_s - T_{fluid}) = (3.32\text{ Btu/h.ft}^2.°\text{F})(3.67\text{ ft}^2)(95-80)°\text{F} = 182.9\text{ Btu/h}$$

Similarly, the rate of heat transfer from the horizontal top surface by natural convection is determined to be

$$L = \frac{4A_{top}}{p} = \frac{4\left(\frac{20}{12}\text{ ft}\right)\left(\frac{24}{12}\text{ ft}\right)}{2\left[\left(\frac{20}{12}\text{ ft}\right)+\left(\frac{24}{12}\text{ ft}\right)\right]} = 1.82\text{ ft}$$



$$A_{top} = \left(\frac{20}{12}\text{ ft}\right)\left(\frac{24}{12}\text{ ft}\right) = 3.33\text{ ft}^2$$

$$h_{conv,top} = 1.32\left(\frac{\Delta T}{L}\right)^{0.25} = 1.32\left(\frac{95-80}{1.82}\right)^{0.25} = 2.24\text{ Btu/h.ft}^2.°\text{F}$$

$$\dot{Q}_{conv,top} = h_{conv,top}A_{top}(T_s - T_{fluid}) = (2.24\text{ Btu/h.ft}^2.°\text{F})(3.33\text{ ft}^2)(95-80)°\text{F} = 111.7\text{ Btu/h}$$

The rate of heat transfer from the outer surfaces of the computer case by radiation is

$$\begin{aligned}\dot{Q}_{rad} &= \varepsilon A_s\sigma(T_s{}^4 - T_{surr}{}^4)\\ &= (0.85)(3.67\text{ ft}^2 + 3.33\text{ ft}^2)(0.1714\text{ Btu/h.ft}^2.\text{R}^4)[(95+460\text{ R})^4 - (80+273\text{ R})^4]\\ &= 100.4\text{ Btu/h}\end{aligned}$$

Then the total rate of heat transfer from the outer surfaces of the computer case becomes

$$\dot{Q}_{total} = \dot{Q}_{conv,side} + \dot{Q}_{conv,top} + \dot{Q}_{rad} = 182.9 + 111.7 + 100.4 = 395\text{ Btu / h}$$

Therefore, the fraction of the heat loss from the outer surfaces of the computer case is

$$f = \frac{(395/3.41214)\text{ W}}{170\text{ W}} = 0.68 = \mathbf{68\%}$$
